# Heat and Mass Transfer

*Fundamentals  
& Applications*

Yunus A. Çengel  
Afshin J. Ghajar

# HEAT AND MASS TRANSFER

FUNDAMENTALS & APPLICATIONS

## ***Quotes on Ethics***

*Without ethics, everything happens as if we were all five billion passengers on a big machinery and nobody is driving the machinery. And it's going faster and faster, but we don't know where.*

—Jacques Cousteau

*Because you're able to do it and because you have the right to do it doesn't mean it's right to do it.*

—Laura Schlessinger

*A man without ethics is a wild beast loosed upon this world.*

—Manly Hall

*The concern for man and his destiny must always be the chief interest of all technical effort. Never forget it among your diagrams and equations.*

—Albert Einstein

*Cowardice asks the question, 'Is it safe?' Expediency asks the question, 'Is it politic?' Vanity asks the question, 'Is it popular?' But, conscience asks the question, 'Is it right?' And there comes a time when one must take a position that is neither safe, nor politic, nor popular but one must take it because one's conscience tells one that it is right.*

—Martin Luther King, Jr

*To educate a man in mind and not in morals is to educate a menace to society.*

—Theodore Roosevelt

*Politics which revolves around benefit is savagery.*

—Said Nursi

*The true test of civilization is, not the census, nor the size of the cities, nor the crops, but the kind of man that the country turns out.*

—Ralph W. Emerson

*The measure of a man's character is what he would do if he knew he never would be found out.*

—Thomas B. Macaulay

# ABOUT THE AUTHORS

**Yunus A. Çengel** is Professor Emeritus of Mechanical Engineering at the University of Nevada, Reno. He received his B.S. in mechanical engineering from Istanbul Technical University and his M.S. and Ph.D. in mechanical engineering from North Carolina State University. His areas of interest are renewable energy, energy efficiency, energy policies, heat transfer enhancement, and engineering education. He served as the director of the Industrial Assessment Center (IAC) at the University of Nevada, Reno, from 1996 to 2000. He has led teams of engineering students to numerous manufacturing facilities in Northern Nevada and California to perform industrial assessments, and has prepared energy conservation, waste minimization, and productivity enhancement reports for them. He has also served as an advisor for various government organizations and corporations.

Dr. Çengel is also the author or coauthor of the widely adopted textbooks *Thermodynamics: An Engineering Approach* (8th ed., 2015), *Fluid Mechanics: Fundamentals and Applications* (3rd ed., 2014), *Fundamentals of Thermal-Fluid Sciences* (3rd ed., 2008), *Introduction to Thermodynamics and Heat Transfer* (2nd ed., 2008), and *Differential Equations for Engineers and Scientists* (1st ed., 2013), all published by McGraw-Hill. Some of his textbooks have been translated into Chinese, Japanese, Korean, Thai, Spanish, Portuguese, Turkish, Italian, Greek, and French.

Dr. Çengel is the recipient of several outstanding teacher awards, and he has received the ASEE Meriam/Wiley Distinguished Author Award for excellence in authorship in 1992 and again in 2000. Dr. Çengel is a registered Professional Engineer in the State of Nevada, and is a member of the American Society of Mechanical Engineers (ASME) and the American Society for Engineering Education (ASEE).

**Afshin J. Ghajar** is *Regents Professor* and *John Brammer Professor* in the School of Mechanical and Aerospace Engineering at Oklahoma State University, Stillwater, Oklahoma, USA and a Honorary Professor of Xi'an Jiaotong University, Xi'an, China. He received his B.S., M.S., and Ph.D. all in Mechanical Engineering from Oklahoma State University. His expertise is in experimental heat transfer/fluid mechanics and development of practical engineering correlations. Dr. Ghajar has made significant contributions to the field of thermal sciences through his experimental, empirical, and numerical works in heat transfer and stratification in sensible heat storage systems, heat transfer to non-Newtonian fluids, heat transfer in the transition region, and non-boiling heat transfer in two-phase flow. His current research is in two-phase flow heat transfer/pressure drop studies in pipes with different orientations, heat transfer/pressure drop in mini/micro tubes, and mixed convective heat transfer/pressure drop in the transition region (plain and enhanced tubes). Dr. Ghajar has been a Summer Research Fellow at Wright Patterson AFB (Dayton, Ohio) and Dow Chemical Company (Freeport, Texas). He and his co-workers have published over 200 reviewed research papers. He has delivered numerous keynote and invited lectures at major technical conferences and institutions. He has received several outstanding teaching, research, advising, and service awards from College of Engineering at Oklahoma State University. His latest award is the 75th Anniversary Medal of the ASME Heat Transfer Division “*in recognition of his service to the heat transfer community and contributions to the field*”. Dr. Ghajar is a *Fellow* of the American Society of Mechanical Engineers (ASME), *Heat Transfer Series Editor* for CRC Press/Taylor & Francis and *Editor-in-Chief* of *Heat Transfer Engineering*, an international journal aimed at practicing engineers and specialists in heat transfer published by Taylor and Francis.

# BRIEF CONTENTS

## CHAPTER ONE

INTRODUCTION AND BASIC CONCEPTS 1

## CHAPTER TWO

HEAT CONDUCTION EQUATION 67

## CHAPTER THREE

STEADY HEAT CONDUCTION 142

## CHAPTER FOUR

TRANSIENT HEAT CONDUCTION 237

## CHAPTER FIVE

NUMERICAL METHODS IN HEAT CONDUCTION 307

## CHAPTER SIX

FUNDAMENTALS OF CONVECTION 379

## CHAPTER SEVEN

EXTERNAL FORCED CONVECTION 424

## CHAPTER EIGHT

INTERNAL FORCED CONVECTION 473

## CHAPTER NINE

NATURAL CONVECTION 533

## CHAPTER TEN

BOILING AND CONDENSATION 598

## CHAPTER ELEVEN

HEAT EXCHANGERS 649

## CHAPTER TWELVE

FUNDAMENTALS OF THERMAL RADIATION 715

## CHAPTER THIRTEEN

RADIATION HEAT TRANSFER 767

## CHAPTER FOURTEEN

MASS TRANSFER 835

## CHAPTER FIFTEEN (WEB CHAPTER)

COOLING OF ELECTRONIC EQUIPMENT

## CHAPTER SIXTEEN (WEB CHAPTER)

HEATING AND COOLING OF BUILDINGS

## CHAPTER SEVENTEEN (WEB CHAPTER)

REFRIGERATION AND FREEZING OF FOODS

## APPENDIX I

PROPERTY TABLES AND CHARTS (SI UNITS) 907

## APPENDIX 2

# CONTENTS

Preface xiii

## CHAPTER ONE INTRODUCTION AND BASIC CONCEPTS 1

- 1–1 Thermodynamics and Heat Transfer 2**
  - Application Areas of Heat Transfer 3
  - Historical Background 3
- 1–2 Engineering Heat Transfer 4**
  - Modeling in Engineering 5
- 1–3 Heat and Other Forms of Energy 6**
  - Specific Heats of Gases, Liquids, and Solids 7
  - Energy Transfer 9
- 1–4 The First Law of Thermodynamics 11**
  - Energy Balance for Closed Systems (*Fixed Mass*) 12
  - Energy Balance for Steady-Flow Systems 12
  - Surface Energy Balance 13
- 1–5 Heat Transfer Mechanisms 17**
- 1–6 Conduction 17**
  - Thermal Conductivity 19
  - Thermal Diffusivity 22
- 1–7 Convection 25**
- 1–8 Radiation 27**
- 1–9 Simultaneous Heat Transfer Mechanisms 30**
- 1–10 Prevention Through Design 35**
- 1–11 Problem-Solving Technique 38**
  - Engineering Software Packages 40
  - Engineering Equation Solver (EES) 41
  - A Remark on Significant Digits 42
- Topic of Special Interest:***
  - Thermal Comfort 43
- Summary 50
- References and Suggested Reading 51
- Problems 51

## CHAPTER TWO HEAT CONDUCTION EQUATION 67

- 2–1 Introduction 68**
  - Steady versus Transient Heat Transfer 69
  - Multidimensional Heat Transfer 70
  - Heat Generation 72
- 2–2 One-Dimensional Heat Conduction Equation 73**
  - Heat Conduction Equation in a Large Plane Wall 73
  - Heat Conduction Equation in a Long Cylinder 75
  - Heat Conduction Equation in a Sphere 76
  - Combined One-Dimensional Heat Conduction Equation 77
- 2–3 General Heat Conduction Equation 79**
  - Rectangular Coordinates 79
  - Cylindrical Coordinates 81
  - Spherical Coordinates 81
- 2–4 Boundary and Initial Conditions 82**
  - 1 Specified Temperature Boundary Condition 84
  - 2 Specified Heat Flux Boundary Condition 84
    - Special Case: Insulated Boundary 85
    - Another Special Case: Thermal Symmetry 85
  - 3 Convection Boundary Condition 86
  - 4 Radiation Boundary Condition 88
  - 5 Interface Boundary Conditions 89
  - 6 Generalized Boundary Conditions 89
- 2–5 Solution of Steady One-Dimensional Heat Conduction Problems 91**
- 2–6 Heat Generation in a Solid 104**
- 2–7 Variable Thermal Conductivity,  $k(T)$  112**
  - Topic of Special Interest:***
    - A Brief Review of Differential Equations 115
  - Classification of Differential Equations 117
  - Solutions of Differential Equations 118
  - General Solution to Selected Differential Equations 119
- Summary 121
- References and Suggested Reading 122
- Problems 122

## CHAPTER THREE

### STEADY HEAT CONDUCTION 142

|            |  |     |
|------------|--|-----|
| <b>3–1</b> | Steady Heat Conduction in Plane Walls    | 143 |
|            | Thermal Resistance Concept               | 144 |
|            | Thermal Resistance Network               | 146 |
|            | Multilayer Plane Walls                   | 148 |
| <b>3–2</b> | Thermal Contact Resistance               | 153 |
| <b>3–3</b> | Generalized Thermal Resistance Networks  | 158 |
| <b>3–4</b> | Heat Conduction in Cylinders and Spheres | 161 |
|            | Multilayered Cylinders and Spheres       | 163 |
| <b>3–5</b> | Critical Radius of Insulation            | 167 |
| <b>3–6</b> | Heat Transfer from Finned Surfaces       | 170 |
|            | Fin Equation                             | 171 |
|            | Fin Efficiency                           | 176 |
|            | Fin Effectiveness                        | 178 |
|            | Proper Length of a Fin                   | 181 |
| <b>3–7</b> | Bioheat Transfer Equation                | 187 |
| <b>3–8</b> | Heat Transfer in Common Configurations   | 192 |
|            | <i>Topic of Special Interest:</i>        |     |
|            | Heat Transfer through Walls and Roofs    | 197 |
|            | Summary                                  | 207 |
|            | References and Suggested Reading         | 209 |
|            | Problems                                 | 209 |

## CHAPTER FOUR

### TRANSIENT HEAT CONDUCTION 237

|            |  |     |
|------------|--|-----|
| <b>4–1</b> | Lumped System Analysis   | 238 |
|            | Criteria for Lumped System Analysis  | 239 |
|            | Some Remarks on Heat Transfer in Lumped Systems  | 241 |
| <b>4–2</b> | Transient Heat Conduction in Large Plane Walls, Long Cylinders, and Spheres with Spatial Effects | 244 |
|            | Nondimensionalized One-Dimensional Transient Conduction Problem                                  | 245 |
|            | Exact Solution of One-Dimensional Transient Conduction Problem                                   | 247 |
|            | Approximate Analytical and Graphical Solutions   | 250 |
| <b>4–3</b> | Transient Heat Conduction in Semi-Infinite Solids  | 261 |
|            | Contact of Two Semi-Infinite Solids  | 265 |
| <b>4–4</b> | Transient Heat Conduction in Multidimensional Systems  | 268 |
|            | <i>Topic of Special Interest:</i>  |     |
|            | Refrigeration and Freezing of Foods  | 276 |

|                                     |     |
|-------------------------------------|-----|
| Control of Microorganisms in Foods  | 276 |
| Refrigeration and Freezing of Foods | 278 |
| Beef Products                       | 279 |
| Poultry Products                    | 283 |
| Summary                             | 287 |
| References and Suggested Reading    | 289 |
| Problems                            | 289 |

## CHAPTER FIVE

### NUMERICAL METHODS IN HEAT CONDUCTION 307

|            |   |     |
|------------|---|-----|
| <b>5–1</b> | Why Numerical Methods?  | 308 |
| 1          | Limitations   | 309 |
| 2          | Better Modeling   | 309 |
| 3          | Flexibility   | 310 |
| 4          | Complications   | 310 |
| 5          | Human Nature  | 310 |
| <b>5–2</b> | Finite Difference Formulation of Differential Equations                       | 311 |
| <b>5–3</b> | One-Dimensional Steady Heat Conduction  | 314 |
|            | Boundary Conditions   | 316 |
|            | Treating Insulated Boundary Nodes as Interior Nodes: The Mirror Image Concept | 318 |
| <b>5–4</b> | Two-Dimensional Steady Heat Conduction  | 325 |
|            | Boundary Nodes  | 326 |
|            | Irregular Boundaries  | 330 |
| <b>5–5</b> | Transient Heat Conduction   | 334 |
|            | Transient Heat Conduction in a Plane Wall                                     | 336 |
|            | Stability Criterion for Explicit Method: Limitation on $\Delta t$             | 338 |
|            | Two-Dimensional Transient Heat Conduction                                     | 347 |
|            | <i>Topic of Special Interest:</i>   |     |
|            | Controlling the Numerical Error   | 352 |
|            | Discretization Error  | 352 |
|            | Round-Off Error   | 353 |
|            | Controlling the Error in Numerical Methods                                    | 354 |
|            | Summary   | 355 |
|            | References and Suggested Reading  | 356 |
|            | Problems  | 357 |

## CHAPTER SIX

### FUNDAMENTALS OF CONVECTION 379

|            |   |     |
|------------|---|-----|
| <b>6–1</b> | Physical Mechanism of Convection        | 380 |
|            | Nusselt Number                          | 382 |
| <b>6–2</b> | Classification of Fluid Flows           | 384 |
|            | Viscous versus Inviscid Regions of Flow | 384 |
|            | Internal versus External Flow           | 384 |
|            | Compressible versus Incompressible Flow | 384 |
|            | Laminar versus Turbulent Flow           | 385 |

Natural (or Unforced) versus Forced Flow 385  
 Steady versus Unsteady Flow 385  
 One-, Two-, and Three-Dimensional Flows 386

### **6–3 Velocity Boundary Layer 387**

Wall Shear Stress 388

### **6–4 Thermal Boundary Layer 389**

Prandtl Number 390

### **6–5 Laminar and Turbulent Flows 390**

Reynolds Number 391

### **6–6 Heat and Momentum Transfer in Turbulent Flow 392**

### **6–7 Derivation of Differential Convection Equations 394**

The Continuity Equation 395

The Momentum Equations 395

Conservation of Energy Equation 397

### **6–8 Solutions of Convection Equations for a Flat Plate 401**

The Energy Equation 403

### **6–9 Nondimensionalized Convection Equations and Similarity 405**

### **6–10 Functional Forms of Friction and Convection Coefficients 406**

### **6–11 Analogies Between Momentum and Heat Transfer 407**

*Topic of Special Interest:*

Microscale Heat Transfer 410

Summary 413

References and Suggested Reading 414

Problems 415

## **CHAPTER SEVEN**

### **EXTERNAL FORCED CONVECTION 424**

### **7–1 Drag and Heat Transfer in External Flow 425**

Friction and Pressure Drag 425

Heat Transfer 427

### **7–2 Parallel Flow over Flat Plates 428**

Friction Coefficient 429

Heat Transfer Coefficient 430

Flat Plate with Unheated Starting Length 432

Uniform Heat Flux 433

### **7–3 Flow across Cylinders and Spheres 438**

Effect of Surface Roughness 440

Heat Transfer Coefficient 442

### **7–4 Flow across Tube Banks 446**

Pressure Drop 449

Summary 453  
 References and Suggested Reading 454  
 Problems 455

## **CHAPTER EIGHT**

### **INTERNAL FORCED CONVECTION 473**

### **8–1 Introduction 474**

### **8–2 Average Velocity and Temperature 475**

Laminar and Turbulent Flow in Tubes 476

### **8–3 The Entrance Region 477**

Entry Lengths 479

### **8–4 General Thermal Analysis 480**

Constant Surface Heat Flux ( $\dot{q}_s = \text{constant}$ ) 481

Constant Surface Temperature ( $T_s = \text{constant}$ ) 482

### **8–5 Laminar Flow in Tubes 485**

Pressure Drop 487

Temperature Profile and the Nusselt Number 489

Constant Surface Heat Flux 489

Constant Surface Temperature 490

Laminar Flow in Noncircular Tubes 491

Developing Laminar Flow in the Entrance Region 492

### **8–6 Turbulent Flow in Tubes 496**

Fully Developed Transitional Flow Heat Transfer 497

Rough Surfaces 498

Developing Turbulent Flow in the Entrance Region 500

Turbulent Flow in Noncircular Tubes 500

Flow through Tube Annulus 500

Heat Transfer Enhancement 501

*Topic of Special Interest:*

Transitional Flow in Tubes 507

Pressure Drop in the Transition Region 508

Heat Transfer in the Transition Region 512

Pressure Drop in the Transition Region

in Mini and Micro Tubes 517

References 517

Summary 518

References and Suggested Reading 519

Problems 520

## **CHAPTER NINE**

### **NATURAL CONVECTION 533**

### **9–1 Physical Mechanism of Natural Convection 534**

### **9–2 Equation of Motion and the Grashof Number 537**

The Grashof Number 539

### **9–3 Natural Convection over Surfaces 540**

Vertical Plates ( $T_s = \text{constant}$ ) 541

Vertical Plates ( $\dot{q}_s = \text{constant}$ ) 541

Vertical Cylinders 543

x  
**CONTENTS**

|   |            |   |            |
|---|------------|---|------------|
| Inclined Plates   | 543        | Effect of Vapor Velocity  | 622        |
| Horizontal Plates   | 544        | The Presence of Noncondensable Gases in Condensers                      | 622        |
| Horizontal Cylinders and Spheres  | 544        |   |            |

## BACKGROUND

**H**eat and mass transfer is a basic science that deals with the rate of transfer of thermal energy. It has a broad application area ranging from biological systems to common household appliances, residential and commercial buildings, industrial processes, electronic devices, and food processing. Students are assumed to have an adequate background in calculus and physics. The completion of first courses in thermodynamics, fluid mechanics, and differential equations prior to taking heat transfer is desirable. However, relevant concepts from these topics are introduced and reviewed as needed.

## OBJECTIVES

This book is intended for undergraduate engineering students in their sophomore or junior year, and as a reference book for practicing engineers. The objectives of this text are

- To cover the *basic principles* of heat transfer.
- To present a wealth of real-world *engineering examples* to give students a feel for how heat transfer is applied in engineering practice.
- To develop an *intuitive understanding* of heat transfer by emphasizing the physics and physical arguments.

It is our hope that this book, through its careful explanations of concepts and its use of numerous practical examples and figures, helps the students develop the necessary skills to bridge the gap between knowledge and the confidence for proper application of that knowledge.

In engineering practice, an understanding of the mechanisms of heat transfer is becoming increasingly important since heat transfer plays a crucial role in the design of vehicles, power plants, refrigerators, electronic devices, buildings, and bridges, among other things. Even a chef needs to have an intuitive understanding of the heat transfer mechanism in order to cook the food “right” by adjusting the rate of heat transfer. We may not be aware of it, but we already use the principles of heat transfer when seeking thermal comfort. We insulate our bodies by putting on heavy coats in winter, and we minimize heat gain by radiation by staying in shady places in summer. We speed up the cooling of hot food by blowing on it and keep warm in cold weather by cuddling up and thus minimizing the exposed surface area. That is, we already use heat transfer whether we realize it or not.

## GENERAL APPROACH

This text is the outcome of an attempt to have a textbook for a practically oriented heat transfer course for engineering students. The text covers the standard topics of heat transfer with an emphasis on physics and real-world applications. This approach is more in line with students' intuition, and makes learning the subject matter enjoyable.

The philosophy that contributed to the overwhelming popularity of the prior editions of this book has remained unchanged in this edition. Namely, our goal has been to offer an engineering textbook that

- Communicates directly to the minds of tomorrow's engineers in a *simple yet precise* manner.
- Leads students toward a clear understanding and firm grasp of the *basic principles* of heat transfer.
- Encourages *creative thinking* and development of a *deeper understanding* and *intuitive feel* for heat transfer.
- Is *read* by students with *interest* and *enthusiasm* rather than being used as an aid to solve problems.

Special effort has been made to appeal to students' natural curiosity and to help them explore the various facets of the exciting subject area of heat transfer. The enthusiastic response we received from the users of prior editions—from small colleges to large universities all over the world—indicates that our objectives have largely been achieved. It is our philosophy that the best way to learn is by practice. Therefore, special effort is made throughout the book to reinforce material that was presented earlier.

Yesterday's engineer spent a major portion of his or her time substituting values into the formulas and obtaining numerical results. However, now formula manipulations and number crunching are being left mainly to the computers. Tomorrow's engineer will have to have a clear understanding and a firm grasp of the *basic principles* so that he or she can understand even the most complex problems, formulate them, and interpret the results. A conscious effort is made to emphasize these basic principles while also providing students with a perspective at how computational tools are used in engineering practice.

## NEW IN THIS EDITION

Some of the primary changes in this fifth edition of the text include new and expanded coverage of heat transfer in biological systems, a new section on the general solutions to selected differential equations, and inclusion of example problems and end of chapter problems which incorporate the new Prevention through Design (PtD) concept. The concept of PtD involves proper use of design to promote safety and reduce accidents and injuries. We also have incorporated over 350 new problems. Each chapter, with the exception of Chapters 5 and 6, now contains one new solved example problem based on the concept of PtD, and a significant part of existing problems were modified. All the popular features of the previous editions are retained. The main body of all chapters, the organization of the text, and the tables and charts in the appendices remain mostly unchanged.

The fifth edition also includes **McGraw-Hill's Connect® Engineering**. This online homework management tool allows assignment of algorithmic problems for homework, quizzes and tests. It connects students with the tools and resources they'll need to achieve success. To learn more, visit [www.mcgrawhillconnect.com](http://www.mcgrawhillconnect.com)

**McGraw-Hill LearnSmart™** is also available as an integrated feature of McGraw-Hill Connect® Engineering. It is an adaptive learning system designed to help students learn faster, study more efficiently, and retain more knowledge for greater success. LearnSmart assesses a student's knowledge of course content through a series of adaptive questions. It pinpoints concepts the student does not understand and maps out a personalized study plan for success. Visit the following site for a demonstration: [www.mhlearnsmart.com](http://www.mhlearnsmart.com)

## FUNDAMENTALS OF ENGINEERING (FE) EXAM PROBLEMS

To prepare students for the Fundamentals of Engineering Exam and to facilitate multiple-choice tests, over 200 *multiple-choice problems* are included in the end-of-chapter problem sets of this edition also. They are placed under the title "Fundamentals of Engineering (FE) Exam Problems" for easy recognition. These problems are intended to check the understanding of fundamentals and to help readers avoid common pitfalls. The EES solutions of these problems are available for instructors for ease of facilitation and easy modification.

## PREVENTION THROUGH DESIGN (PtD) PROBLEMS

In 2007, the National Institute for Occupational Safety and Health launched the National Prevention through Design (PtD) initiative, with the mission to prevent or reduce work-related injuries, illnesses, and fatalities by including prevention considerations in all circumstances that impact individuals in the workplace. As such, the concept of PtD involves applying the means of reducing risks and preventing hazards in the design of equipment, tools, processes, and work facilities. The PtD concept is first introduced in Chapter 1. The idea of having example problems and end of chapter problems throughout the different chapters in the text is not only to simply provide discussions of interesting real world applications, but also to introduce the concepts of PtD to the minds of tomorrow's engineers whereby they may influence a change in culture toward more emphasis on safety designs.

## NEW COVERAGE OF HEAT TRANSFER IN BIOLOGICAL SYSTEMS

Thermal Comfort is presented as a Topic of Special Interest in Chapter 1. This section is expanded and the term *thermoregulation* is introduced in this section. Thermoregulation means the body has mechanisms to act as a thermostat, when the core body temperature deviates from the normal resting value. Thermoregulation in the human body is achieved by keeping a tight balance between heat gain and heat loss. The "Bioheat Transfer Equation" introduced in Chapter 3 is used to calculate the heat transfer between a human body and its surroundings. Thermoregulation can be adjusted by both behavioral changes and physiological changes. Behavioral changes could be relocating to a more desirable environment within the structure or putting on more clothing. Physiological changes include blood vessel diameter changes and the production of sweat. However, under normal conditions, few of these changes

are needed because of the efficient organization of arteries and veins; they are arranged as a counter-current heat exchanger. This concept is presented in Chapter 11 as a Topic of Special Interest “The Human Cardiovascular System as a Counter-Current Heat Exchanger”.

### EXPANDED COVERAGE OF MINI AND MICRO TUBES

Owing to the rapid advancement in fabrication techniques, the use of the miniaturized devices and components is ever increasing. Whether it is in the application of miniature heat exchangers, fuel cells, pumps, compressors, turbines, sensors, or artificial blood vessels, a sound understanding of fluid flow in micro-scale channels and tubes is essential. Microscale Heat Transfer is presented as a Topic of Special Interest in Chapter 6. This edition expands the coverage of plain mini and micro tubes to spiral micro-fin tubes in Chapter 8.

### THREE ONLINE APPLICATION CHAPTERS

The application chapters “Cooling of Electronic Equipment” (Chapter 15), “Heating and Cooling of Buildings” (Chapter 16), and “Refrigeration and Freezing of Foods” (Chapter 17) are available for download via the text website; go to [www.mhhe.com/cengel](http://www.mhhe.com/cengel) for detailed coverage of these topics.

### CONTENT CHANGES AND REORGANIZATION

With the exception of the changes already mentioned, minor changes are made in the main body of the text. Over 350 new problems are added, and a significant number of the existing problems are revised. The noteworthy changes in various chapters are summarized here for those who are familiar with the previous edition.

- In Chapter 1, the concept of Prevention through Design (PtD) has been introduced by Dr. Clement C. Tang of University of North Dakota. In addition, the coverage of Thermal Comfort presented as a Topic of Special Interest has been expanded by Dr. David A. Rubenstein of Stony Brook University.
- In Chapter 2, a new section “General Solution to Selected Differential Equations” is added.
- In Chapter 3, a new section “Bioheat Transfer Equation” is added.
- In Chapter 5, the section on “Interactive SS-T-CONDUCT Software” which introduced the software and demonstrated its use has been deleted and moved to text website. This information and the software are available from the online learning center ([www.mhhe.com/cengel](http://www.mhhe.com/cengel)) to the instructors and students. The software can be used to solve or to check the solutions of many of the one- and two-dimensional heat conduction problems with uniform energy generation in rectangular geometries.
- In Chapter 8, a new subsection “Fully Developed Transitional Flow Heat Transfer” is added. Also, the coverage of subsections on “Pressure Drop in the Transition Region” and “Heat Transfer in the Transition Region” of the Topic of Special Interest on Transitional Flow in Tubes has been expanded.
- In Chapter 10, the coverage of the Topic of Special Interest on “Non-Boiling Two-Phase Flow Heat Transfer” has been expanded and a new

subsection on “Application of Reynolds Analogy to Non-Boiling Two-Phase Flow” has been added.

- In Chapter 11, the coverage of Heat Exchangers has been expanded and this chapter now has the Topic of Special Interest “The Human Cardiovascular System as a Counter-Current Heat Exchanger” contributed by Dr. David A. Rubenstein of Stony Brook University.
- In Chapter 14, the section on Water Vapor Migration in Buildings has been expanded.

## LEARNING TOOLS

### EMPHASIS ON PHYSICS

The authors believe that the emphasis in undergraduate education should remain on *developing a sense of underlying physical mechanisms* and a *mastery of solving practical problems* that an engineer is likely to face in the real world.

### EFFECTIVE USE OF ASSOCIATION

An observant mind should have no difficulty understanding engineering sciences. After all, the principles of engineering sciences are based on our *everyday experiences and experimental observations*. The process of cooking, for example, serves as an excellent vehicle to demonstrate the basic principles of heat transfer.

### SELF-INSTRUCTING

The material in the text is introduced at a level that an average student can follow comfortably. It speaks *to* students, not *over* students. In fact, it is *self-instructive*. The order of coverage is from *simple* to *general*.

### EXTENSIVE USE OF ARTWORK

Art is an important learning tool that helps students “get the picture.” The fifth edition of *Heat and Mass Transfer: Fundamentals & Applications* contains more figures and illustrations than any other book in this category.

### LEARNING OBJECTIVES AND SUMMARIES

Each chapter begins with an *Overview* of the material to be covered and chapter-specific *Learning Objectives*. A *Summary* is included at the end of each chapter, providing a quick review of basic concepts and important relations, and pointing out the relevance of the material.

### NUMEROUS WORKED-OUT EXAMPLES WITH A SYSTEMATIC SOLUTIONS PROCEDURE

Each chapter contains several worked-out *examples* that clarify the material and illustrate the use of the basic principles. An *intuitive* and *systematic* approach is used in the solution of the example problems, while maintaining an informal conversational style. The problem is first stated, and the objectives are identified. The assumptions are then stated, together with their justifications. The properties needed to solve the problem are listed separately,

if appropriate. This approach is also used consistently in the solutions presented in the instructor's solutions manual.

## A WEALTH OF REAL-WORLD END-OF-CHAPTER PROBLEMS

The end-of-chapter problems are grouped under specific topics to make problem selection easier for both instructors and students. Within each group of problems are:

- **Concept Questions**, indicated by “C,” to check the students’ level of understanding of basic concepts.
- **Review Problems** are more comprehensive in nature and are not directly tied to any specific section of a chapter—in some cases they require review of material learned in previous chapters.
- **Fundamentals of Engineering (FE) Exam Problems** are designed to help students prepare for the *Fundamentals of Engineering* exam, as they prepare for their Professional Engineering license.

 These problems are “Prevention through Design” related problems.

 These problems are solved using EES, and complete solutions together with parametric studies are included on the textbook’s website.

 These problems are comprehensive in nature and are intended to be solved with a computer, possibly using the EES software.

- **Design and Essay** are intended to encourage students to make engineering judgments, to conduct independent exploration of topics of interest, and to communicate their findings in a professional manner.

Several economics- and safety-related problems are incorporated throughout to enhance cost and safety awareness among engineering students. Answers to selected problems are listed immediately following the problem for convenience to students.

## A CHOICE OF SI ALONE OR SI/ENGLISH UNITS

In recognition of the fact that English units are still widely used in some industries, both SI and English units are used in this text, with an emphasis on SI. The material in this text can be covered using combined SI/English units or SI units alone, depending on the preference of the instructor. The property tables and charts in the appendices are presented in both units, except the ones that involve dimensionless quantities. Problems, tables, and charts in English units are designated by “E” after the number for easy recognition, and they can be ignored by SI users.

## TOPICS OF SPECIAL INTEREST

Most chapters contain a real world application, end-of-chapter optional section called “Topic of Special Interest” where interesting applications of heat transfer are discussed such as *Thermal Comfort* in Chapter 1, *Heat Transfer through the Walls and Roofs* in Chapter 3, *Microscale Heat Transfer* in Chapter 6, *Transitional Flow in Tubes* in Chapter 8, *Heat Transfer through Windows* in

Chapter 9, *Non-Boiling Two-Phase Flow Heat Transfer* in Chapter 10, *Human Cardiovascular System as a Counter-Current Heat Exchanger* in Chapter 11, and *Heat Transfer from the Human Body* in Chapter 13.

## CONVERSION FACTORS

Frequently used conversion factors and physical constants are listed on the inner cover pages of the text for easy reference.

## SUPPLEMENTS

The following supplements are available to the users of the book.

### ENGINEERING EQUATION SOLVER (EES)

Developed by Sanford Klein and William Beckman from the University of Wisconsin—Madison, this software combines equation-solving capability and engineering property data. EES can do optimization, parametric analysis, and linear and nonlinear regression, and provides publication-quality plotting capabilities. Thermodynamics and transport properties for air, water, and many other fluids are built in, and EES allows the user to enter property data or functional relationships.

EES is a powerful equation solver with built-in functions and property tables for thermodynamic and transport properties as well as automatic unit checking capability. It requires less time than a calculator for data entry and allows more time for thinking critically about modeling and solving engineering problems. Look for the EES icons in the homework problems sections of the text.

The Limited Academic Version of EES is available for departmental license upon adoption of the Fifth Edition of Heat and Mass Transfer: Fundamentals and Applications (meaning that the text is required for students in the course). You may load this software onto your institution's computer system, for use by students and faculty related to the course, as long as the arrangement between McGraw-Hill Education and F-Chart is in effect. There are minimum order requirements stipulated by F-Chart to qualify.

### TEXT WEBSITE

Web support is provided for the text on the text specific website at [www.mhhe.com/cengel](http://www.mhhe.com/cengel)

Visit this website for general text information, errata, and author information. The site also includes resources for students including a list of helpful web links. The instructor side of the site includes the solutions manual, the text's images in PowerPoint form, and more!

### COSMOS

(Available to Instructors Only)

McGraw-Hill's COSMOS (Complete Online Solutions Manual Organization System) allows instructors to streamline the creation of assignments, quizzes, and texts by using problems and solutions from the textbook, as well as their own custom material. COSMOS is now available online at <http://cosmos.mhhe.com>

## ACKNOWLEDGMENTS

We would like to acknowledge with appreciation the contribution of new sections, problems, and the numerous and valuable comments, suggestions, constructive criticisms, and praise from the following contributors, evaluators and reviewers:

# INTRODUCTION AND BASIC CONCEPTS

The science of thermodynamics deals with the *amount* of heat transfer as a system undergoes a process from one equilibrium state to another, and makes no reference to *how long* the process will take. But in engineering, we are often interested in the *rate* of heat transfer, which is the topic of the science of *heat transfer*.

We start this chapter with a review of the fundamental concepts of thermodynamics that form the framework for heat transfer. We first present the relation of heat to other forms of energy and review the energy balance. We then present the three basic mechanisms of heat transfer, which are conduction, convection, and radiation, and discuss thermal conductivity. *Conduction* is the transfer of energy from the more energetic particles of a substance to the adjacent, less energetic ones as a result of interactions between the particles. *Convection* is the mode of heat transfer between a solid surface and the adjacent liquid or gas that is in motion, and it involves the combined effects of conduction and fluid motion. *Radiation* is the energy emitted by matter in the form of electromagnetic waves (or photons) as a result of the changes in the electronic configurations of the atoms or molecules. We close this chapter with a discussion of simultaneous heat transfer.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Understand how thermodynamics and heat transfer are related to each other,
- Distinguish thermal energy from other forms of energy, and heat transfer from other forms of energy transfer,
- Perform general energy balances as well as surface energy balances,
- Understand the basic mechanisms of heat transfer, which are conduction, convection, and radiation, and Fourier's law of heat conduction, Newton's law of cooling, and the Stefan–Boltzmann law of radiation,
- Identify the mechanisms of heat transfer that occur simultaneously in practice,
- Develop an awareness of the cost associated with heat losses, and
- Solve various heat transfer problems encountered in practice.

## 1–1 • THERMODYNAMICS AND HEAT TRANSFER

We all know from experience that a cold canned drink left in a room warms up and a warm canned drink left in a refrigerator cools down. This is accomplished by the transfer of *energy* from the warm medium to the cold one. The energy transfer is always from the higher temperature medium to the lower temperature one, and the energy transfer stops when the two mediums reach the same temperature.

You will recall from thermodynamics that energy exists in various forms. In this text we are primarily interested in **heat**, which is *the form of energy that can be transferred from one system to another as a result of temperature difference*. The science that deals with the determination of the *rates* of such energy transfers is **heat transfer**.

You may be wondering why we need to undertake a detailed study on heat transfer. After all, we can determine the amount of heat transfer for any system undergoing any process using a thermodynamic analysis alone. The reason is that thermodynamics is concerned with the *amount* of heat transfer as a system undergoes a process from one equilibrium state to another, and it gives no indication about *how long* the process will take. A thermodynamic analysis simply tells us how much heat must be transferred to realize a specified change of state to satisfy the conservation of energy principle.

In practice we are more concerned about the rate of heat transfer (heat transfer per unit time) than we are with the amount of it. For example, we can determine the amount of heat transferred from a thermos bottle as the hot coffee inside cools from 90°C to 80°C by a thermodynamic analysis alone. But a typical user or designer of a thermos bottle is primarily interested in *how long* it will be before the hot coffee inside cools to 80°C, and a thermodynamic analysis cannot answer this question. Determining the rates of heat transfer to or from a system and thus the times of heating or cooling, as well as the variation of the temperature, is the subject of *heat transfer* (Fig. 1–1).

Thermodynamics deals with equilibrium states and changes from one equilibrium state to another. Heat transfer, on the other hand, deals with systems that lack thermal equilibrium, and thus it is a *nonequilibrium* phenomenon. Therefore, the study of heat transfer cannot be based on the principles of thermodynamics alone. However, the laws of thermodynamics lay the framework for the science of heat transfer. The *first law* requires that the rate of energy transfer into a system be equal to the rate of increase of the energy of that system. The *second law* requires that heat be transferred in the direction of decreasing temperature (Fig. 1–2). This is like a car parked on an inclined road must go downhill in the direction of decreasing elevation when its brakes are released. It is also analogous to the electric current flowing in the direction of decreasing voltage or the fluid flowing in the direction of decreasing total pressure.

The basic requirement for heat transfer is the presence of a *temperature difference*. There can be no net heat transfer between two bodies that are at the same temperature. The temperature difference is the *driving force* for heat transfer, just as the *voltage difference* is the driving force for electric current flow and *pressure difference* is the driving force for fluid flow. The rate of heat transfer in a certain direction depends on the magnitude of the *temperature gradient* (the temperature difference per unit length or the rate of change of temperature) in that direction. The larger the temperature gradient, the higher the rate of heat transfer.

**FIGURE 1–1**

We are normally interested in how long it takes for the hot coffee in a thermos bottle to cool to a certain temperature, which cannot be determined from a thermodynamic analysis alone.

**FIGURE 1–2**

Heat flows in the direction of decreasing temperature.

## Application Areas of Heat Transfer

Heat transfer is commonly encountered in engineering systems and other aspects of life, and one does not need to go very far to see some application areas of heat transfer. In fact, one does not need to go anywhere. The human body is constantly rejecting heat to its surroundings, and human comfort is closely tied to the rate of this heat rejection. We try to control this heat transfer rate by adjusting our clothing to the environmental conditions.

Many ordinary household appliances are designed, in whole or in part, by using the principles of heat transfer. Some examples include the electric or gas range, the heating and air-conditioning system, the refrigerator and freezer, the water heater, the iron, and even the computer, the TV, and the DVD player. Of course, energy-efficient homes are designed on the basis of minimizing heat loss in winter and heat gain in summer. Heat transfer plays a major role in the design of many other devices, such as car radiators, solar collectors, various components of power plants, and even spacecraft (Fig. 1–3). The optimal insulation thickness in the walls and roofs of the houses, on hot water or steam pipes, or on water heaters is again determined on the basis of a heat transfer analysis with economic consideration.

### Historical Background

Heat has always been perceived to be something that produces in us a sensation of warmth, and one would think that the nature of heat is one of the first

**FIGURE 1–4**

In the early nineteenth century, heat was thought to be an invisible fluid called the *caloric* that flowed from warmer bodies to the cooler ones.

things understood by mankind. But it was only in the middle of the nineteenth century that we had a true physical understanding of the nature of heat, thanks to the development at that time of the **kinetic theory**, which treats molecules as tiny balls that are in motion and thus possess kinetic energy. Heat is then defined as the energy associated with the random motion of atoms and molecules. Although it was suggested in the eighteenth and early nineteenth centuries that heat is the manifestation of motion at the molecular level (called the *live force*), the prevailing view of heat until the middle of the nineteenth century was based on the **caloric theory** proposed by the French chemist Antoine Lavoisier (1743–1794) in 1789. The caloric theory asserts that heat is a fluid-like substance called the **caloric** that is a massless, colorless, odorless, and tasteless substance that can be poured from one body into another (Fig. 1–4). When caloric was added to a body, its temperature increased; and when caloric was removed from a body, its temperature decreased. When a body could not contain any more caloric, much the same way as when a glass of water could not dissolve any more salt or sugar, the body was said to be saturated with caloric. This interpretation gave rise to the terms *saturated liquid* and *saturated vapor* that are still in use today.

The caloric theory came under attack soon after its introduction. It maintained that heat is a substance that could not be created or destroyed. Yet it was known that heat can be generated indefinitely by rubbing one's hands together or rubbing two pieces of wood together. In 1798, the American Benjamin Thompson (Count Rumford) (1753–1814) showed in his papers that heat can be generated continuously through friction. The validity of the caloric theory was also challenged by several others. But it was the careful experiments of the Englishman James P. Joule (Fig. 1–5) published in 1843 that finally convinced the skeptics that heat was not a substance after all, and thus put the caloric theory to rest. Although the caloric theory was totally abandoned in the middle of the nineteenth century, it contributed greatly to the development of thermodynamics and heat transfer.

## 1–2 ■ ENGINEERING HEAT TRANSFER

Heat transfer equipment such as heat exchangers, boilers, condensers, radiators, heaters, furnaces, refrigerators, and solar collectors are designed primarily on the basis of heat transfer analysis. The heat transfer problems encountered in practice can be considered in two groups: (1) *rating* and (2) *sizing* problems. The rating problems deal with the determination of the heat transfer rate for an existing system at a specified temperature difference. The sizing problems deal with the determination of the size of a system in order to transfer heat at a specified rate for a specified temperature difference.

An engineering device or process can be studied either *experimentally* (testing and taking measurements) or *analytically* (by analysis or calculations). The experimental approach has the advantage that we deal with the actual physical system, and the desired quantity is determined by measurement, within the limits of experimental error. However, this approach is expensive, timeconsuming, and often impractical. Besides, the system we are analyzing may not even exist. For example, the entire heating and plumbing systems of a building must usually be sized *before* the building is actually built on the basis of the specifications given. The analytical approach (including the

numerical approach) has the advantage that it is fast and inexpensive, but the results obtained are subject to the accuracy of the assumptions, approximations, and idealizations made in the analysis. In engineering studies, often a good compromise is reached by reducing the choices to just a few by analysis, and then verifying the findings experimentally.

## Modeling in Engineering

The descriptions of most scientific problems involve equations that relate the changes in some key variables to each other. Usually the smaller the increment chosen in the changing variables, the more general and accurate the description. In the limiting case of infinitesimal or differential changes in variables, we obtain differential equations that provide precise mathematical formulations for the physical principles and laws by representing the rates of change as derivatives. Therefore, differential equations are used to investigate a wide variety of problems in sciences and engineering (Fig. 1–6). However, many problems encountered in practice can be solved without resorting to differential equations and the complications associated with them.

The study of physical phenomena involves two important steps. In the first step, all the variables that affect the phenomena are identified, reasonable assumptions and approximations are made, and the interdependence of these variables is studied. The relevant physical laws and principles are invoked, and the problem is formulated mathematically. The equation itself is very instructive as it shows the degree of dependence of some variables on others, and the relative importance of various terms. In the second step, the problem is solved using an appropriate approach, and the results are interpreted.

Many processes that seem to occur in nature randomly and without any order are, in fact, being governed by some visible or not-so-visible physical laws. Whether we notice them or not, these laws are there, governing consistently and predictably what seem to be ordinary events. Most of these laws are well defined and well understood by scientists. This makes it possible to predict the course of an event before it actually occurs, or to study various aspects of an event mathematically without actually running expensive and timeconsuming experiments. This is where the power of analysis lies. Very accurate results to meaningful practical problems can be obtained with relatively little effort by using a suitable and realistic mathematical model. The preparation of such models requires an adequate knowledge of the natural phenomena involved and the relevant laws, as well as a sound judgment. An unrealistic model will obviously give inaccurate and thus unacceptable results.

An analyst working on an engineering problem often finds himself or herself in a position to make a choice between a very accurate but complex model, and a simple but not-so-accurate model. The right choice depends on the situation at hand. The right choice is usually the simplest model that yields adequate results. For example, the process of baking potatoes or roasting a round chunk of beef in an oven can be studied analytically in a simple way by modeling the potato or the roast as a spherical solid ball that has the properties of water (Fig. 1–7). The model is quite simple, but the results obtained are sufficiently accurate for most practical purposes. As another example, when we analyze the heat losses from a building in order to select the right size for a heater, we determine the heat losses under anticipated worst conditions and select a furnace that will provide sufficient energy to make up for those

**FIGURE 1–5**

**James Prescott Joule** (1818–1889) is a British physicist born in Salford,

Lancashire, England. Joule is best known for his work on the conversion of electrical and mechanical energy into heat and the first law of thermodynamics. The energy unit joule (J) is named after him. The Joule's law of electric heating that he formulated states that the rate of heat production in a conducting wire is proportional to the product of the resistance of the wire and the square of the electric current.

Through his experiments, Joule has demonstrated the mechanical equivalence of heat, i.e., the conversion of mechanical energy into an equivalent amount of thermal energy, which laid the foundation for the conservation of energy principle. Joule, together with William Thomson (later Lord Kelvin), discovered the temperature drop of a substance during free expansion, a phenomenon known as the Joule-Thomson effect, which forms the foundation of the operation of the common vapor-compression refrigeration and air conditioning systems.

**FIGURE 1–6**

Mathematical modeling of physical problems.

losses. Often we tend to choose a larger furnace in anticipation of some future expansion, or just to provide a factor of safety. A very simple analysis is adequate in this case.

When selecting heat transfer equipment, it is important to consider the actual operating conditions. For example, when purchasing a heat exchanger that will handle hard water, we must consider that some calcium deposits will form on the heat transfer surfaces over time, causing fouling and thus a gradual decline in performance. The heat exchanger must be selected on the basis of operation under these adverse conditions instead of under new conditions.

Preparing very accurate but complex models is usually not so difficult. But such models are not much use to an analyst if they are very difficult and time-consuming to solve. At the minimum, the model should reflect the essential features of the physical problem it represents. There are many significant real-world problems that can be analyzed with a simple model. But it should always be kept in mind that the results obtained from an analysis are as accurate as the assumptions made in simplifying the problem. Therefore, the solution obtained should not be applied to situations for which the original assumptions do not hold.

A solution that is not quite consistent with the observed nature of the problem indicates that the mathematical model used is too crude. In that case, a more realistic model should be prepared by eliminating one or more of the questionable assumptions. This will result in a more complex problem that, of course, is more difficult to solve. Thus any solution to a problem should be interpreted within the context of its formulation.

### 1–3 ▪ HEAT AND OTHER FORMS OF ENERGY

Energy can exist in numerous forms such as thermal, mechanical, kinetic, potential, electrical, magnetic, chemical, and nuclear, and their sum constitutes the **total energy**  $E$  (or  $e$  on a unit mass basis) of a system. The forms of energy related to the molecular structure of a system and the degree of the molecular activity are referred to as the *microscopic energy*. The sum of all microscopic forms of energy is called the **internal energy** of a system, and is denoted by  $U$  (or  $u$  on a unit mass basis).

The international unit of energy is *joule* (J) or *kilojoule* (1 kJ = 1000 J). In the English system, the unit of energy is the *British thermal unit* (Btu), which is defined as the energy needed to raise the temperature of 1 lbm of water at 60°F by 1°F. The magnitudes of kJ and Btu are almost identical (1 Btu = 1.055056 kJ). Another well known unit of energy is the *calorie* (1 cal = 4.1868 J), which is defined as the energy needed to raise the temperature of 1 gram of water at 14.5°C by 1°C.

Internal energy may be viewed as the sum of the kinetic and potential energies of the molecules. The portion of the internal energy of a system associated with the kinetic energy of the molecules is called **sensible energy** or **sensible heat**. The average velocity and the degree of activity of the molecules are proportional to the temperature. Thus, at higher temperatures the molecules possess higher kinetic energy, and as a result, the system has a higher internal energy.

The internal energy is also associated with the intermolecular forces between the molecules of a system. These are the forces that bind the molecules to each

**FIGURE 1–7**

Modeling is a powerful engineering tool that provides great insight and simplicity at the expense of some accuracy.

other, and, as one would expect, they are strongest in solids and weakest in gases. If sufficient energy is added to the molecules of a solid or liquid, they will overcome these molecular forces and simply break away, turning the system to a gas. This is a *phase change* process and because of this added energy, a system in the gas phase is at a higher internal energy level than it is in the solid or the liquid phase. The internal energy associated with the phase of a system is called **latent energy** or **latent heat**.

The changes mentioned above can occur without a change in the chemical composition of a system. Most heat transfer problems fall into this category, and one does not need to pay any attention to the forces binding the atoms in a molecule together. The internal energy associated with the atomic bonds in a molecule is called **chemical (or bond) energy**, whereas the internal energy associated with the bonds within the nucleus of the atom itself is called **nuclear energy**. The chemical and nuclear energies are absorbed or released during chemical or nuclear reactions, respectively.

In the analysis of systems that involve fluid flow, we frequently encounter the combination of properties  $u$  and  $Pv$ . For the sake of simplicity and convenience, this combination is defined as **enthalpy**  $h$ . That is,  $h = u + Pv$  where the term  $Pv$  represents the *flow energy* of the fluid (also called the *flow work*), which is the energy needed to push a fluid and to maintain flow. In the energy analysis of flowing fluids, it is convenient to treat the flow energy as part of the energy of the fluid and to represent the microscopic energy of a fluid stream by enthalpy  $h$  (Fig. 1–8).

**FIGURE 1–8**

The *internal energy*  $u$  represents the microscopic energy of a nonflowing fluid, whereas *enthalpy*  $h$  represents the microscopic energy of a flowing fluid.

## Specific Heats of Gases, Liquids, and Solids

You may recall that an **ideal gas** is defined as a gas that obeys the relation

$$PV = RT \quad \text{or} \quad P = \rho RT \quad (1-1)$$

where  $P$  is the absolute pressure,  $v$  is the specific volume,  $T$  is the thermodynamic (or absolute) temperature,  $\rho$  is the density, and  $R$  is the gas constant. It has been experimentally observed that the ideal gas relation given above closely approximates the  $P$ - $v$ - $T$  behavior of real gases at low densities. At low pressures and high temperatures, the density of a gas decreases and the gas behaves like an ideal gas. In the range of practical interest, many familiar gases such as air, nitrogen, oxygen, hydrogen, helium, argon, neon, and krypton and even heavier gases such as carbon dioxide can be treated as ideal gases with negligible error (often less than one percent). Dense gases such as water vapor in steam power plants and refrigerant vapor in refrigerators, however, should not always be treated as ideal gases since they usually exist at a state near saturation.

You may also recall that **specific heat** is defined as *the energy required to raise the temperature of a unit mass of a substance by one degree* (Fig. 1–9). In general, this energy depends on how the process is executed. We are usually interested in two kinds of specific heats: specific heat at constant volume  $c_v$  and specific heat at constant pressure  $c_p$ . The **specific heat at constant volume**  $c_v$  can be viewed as the energy required to raise the temperature of a unit mass of a substance by one degree as the volume is held constant. The energy required to do the same as the pressure is held constant is the **specific heat at constant pressure**  $c_p$ . The specific heat at constant pressure  $c_p$  is greater

**FIGURE 1–9**

Specific heat is the energy required to raise the temperature of a unit mass of a substance by one degree in a specified way.

**FIGURE 1-10**

The specific heat of a substance changes with temperature.

than  $c_v$  because at constant pressure the system is allowed to expand and the energy for this expansion work must also be supplied to the system. For ideal gases, these two specific heats are related to each other by  $c_p = c_v + R$ .

A common unit for specific heats is  $\text{kJ/kg} \cdot ^\circ\text{C}$  or  $\text{kJ/kg} \cdot \text{K}$ . Notice that these two units are *identical* since  $\Delta T(^{\circ}\text{C}) = \Delta T(\text{K})$ , and  $1^{\circ}\text{C}$  change in temperature is equivalent to a change of 1 K. Also,

$$1 \text{ kJ/kg} \cdot ^\circ\text{C} \equiv 1 \text{ J/g} \cdot ^\circ\text{C} \equiv 1 \text{ kJ/kg} \cdot \text{K} \equiv 1 \text{ J/g} \cdot \text{K}$$

The specific heats of a substance, in general, depend on two independent properties such as temperature and pressure. For an *ideal gas*, however, they depend on *temperature* only (Fig. 1-10). At low pressures all real gases approach ideal gas behavior, and therefore their specific heats depend on temperature only.

The differential changes in the internal energy  $u$  and enthalpy  $h$  of an ideal gas can be expressed in terms of the specific heats as

$$du = c_v dT \quad \text{and} \quad dh = c_p dT \quad (1-2)$$

The finite changes in the internal energy and enthalpy of an ideal gas during a process can be expressed approximately by using specific heat values at the average temperature as

$$\Delta u = c_{v,\text{avg}} \Delta T \quad \text{and} \quad \Delta h = c_{p,\text{avg}} \Delta T \quad (\text{J/g}) \quad (1-3)$$

or

$$\Delta U = mc_{v,\text{avg}} \Delta T \quad \text{and} \quad \Delta H = mc_{p,\text{avg}} \Delta T \quad (\text{J}) \quad (1-4)$$

where  $m$  is the mass of the system.

A substance whose specific volume (or density) does not change with temperature or pressure is called an **incompressible substance**. The specific volumes of solids and liquids essentially remain constant during a process, and thus they can be approximated as incompressible substances without sacrificing much in accuracy.

The constant-volume and constant-pressure specific heats are identical for incompressible substances (Fig. 1-11). Therefore, for solids and liquids the subscripts on  $c_v$  and  $c_p$  can be dropped and both specific heats can be represented by a single symbol,  $c$ . That is,  $c_p \equiv c_v \equiv c$ . This result could also be deduced from the physical definitions of constant-volume and constant-pressure specific heats. Specific heats of several common gases, liquids, and solids are given in the Appendix.

The specific heats of incompressible substances depend on temperature only. Therefore, the change in the internal energy of solids and liquids can be expressed as

$$\Delta U = mc_{\text{avg}} \Delta T \quad (\text{J}) \quad (1-5)$$

**FIGURE 1-11**

The  $c_v$  and  $c_p$  values of incompressible substances are identical and are denoted by  $c$ .

where  $c_{\text{avg}}$  is the average specific heat evaluated at the average temperature. Note that the internal energy change of the systems that remain in a single phase (liquid, solid, or gas) during the process can be determined very easily using average specific heats.

## Energy Transfer

Energy can be transferred to or from a given mass by two mechanisms: *heat transfer*  $Q$  and *work*  $W$ . An energy interaction is heat transfer if its driving force is a temperature difference. Otherwise, it is work. A rising piston, a rotating shaft, and an electrical wire crossing the system boundaries are all associated with work interactions. Work done *per unit time* is called **power**, and is denoted by  $W$ . The unit of power is W or hp (1 hp = 746 W). Car engines and hydraulic, steam, and gas turbines produce work; compressors, pumps, and mixers consume work. Notice that the energy of a system decreases as it does work, and increases as work is done on it.

In daily life, we frequently refer to the sensible and latent forms of internal energy as **heat**, and we talk about the heat content of bodies (Fig. 1–12). In thermodynamics, however, those forms of energy are usually referred to as **thermal energy** to prevent any confusion with *heat transfer*.

The term *heat* and the associated phrases such as *heat flow*, *heat addition*, *heat rejection*, *heat absorption*, *heat gain*, *heat loss*, *heat storage*, *heat generation*, *electrical heating*, *latent heat*, *body heat*, and *heat source* are in common use today, and the attempt to replace *heat* in these phrases by *thermal energy* had only limited success. These phrases are deeply rooted in our vocabulary and they are used by both ordinary people and scientists without causing any misunderstanding. For example, the phrase *body heat* is understood to mean the *thermal energy content* of a body. Likewise, *heat flow* is understood to mean the *transfer of thermal energy*, not the flow of a fluid-like substance called *heat*, although the latter incorrect interpretation, based on the caloric theory, is the origin of this phrase. Also, the transfer of heat into a system is frequently referred to as *heat addition* and the transfer of heat out of a system as *heat rejection*.

Keeping in line with current practice, we will refer to the thermal energy as *heat* and the transfer of thermal energy as *heat transfer*. The amount of heat transferred during the process is denoted by  $Q$ . The amount of heat transferred per unit time is called **heat transfer rate**, and is denoted by  $\dot{Q}$ . The overdot stands for the time derivative, or “per unit time.” The heat transfer rate  $\dot{Q}$  has the unit J/s, which is equivalent to W.

When the *rate* of heat transfer  $\dot{Q}$  is available, then the total amount of heat transfer  $Q$  during a time interval  $\Delta t$  can be determined from

$$Q = \int_0^{\Delta t} \dot{Q} dt \quad (\text{J}) \quad (1-6)$$

provided that the variation of  $\dot{Q}$  with time is known. For the special case of  $\dot{Q} = \text{constant}$ , the equation above reduces to

$$Q = \dot{Q} \Delta t \quad (\text{J}) \quad (1-7)$$

**FIGURE 1–12**

The sensible and latent forms of internal energy can be transferred as a result of a temperature difference, and they are referred to as *heat* or *thermal energy*.

**FIGURE 1-13**

Heat flux is heat transfer *per unit time* and *per unit area*, and is equal to  $\dot{q} = \dot{Q}/A$  when  $\dot{Q}$  is uniform over the area  $A$ .

**FIGURE 1-14**

Schematic for Example 1-1.

The rate of heat transfer per unit area normal to the direction of heat transfer is called **heat flux**, and the average heat flux is expressed as (Fig. 1-13)

$$\dot{q} = \frac{\dot{Q}}{A} \quad (\text{W/m}^2) \quad (1-8)$$

where  $A$  is the heat transfer area. The unit of heat flux in English units is  $\text{Btu/h}\cdot\text{ft}^2$ . Note that heat flux may vary with time as well as position on a surface.

### EXAMPLE 1-1 Heating of a Copper Ball

A 10-cm-diameter copper ball is to be heated from  $100^\circ\text{C}$  to an average temperature of  $150^\circ\text{C}$  in 30 minutes (Fig. 1-14). Taking the average density and specific heat of copper in this temperature range to be  $\rho = 8950 \text{ kg/m}^3$  and  $c_p = 0.395 \text{ kJ/kg}\cdot\text{C}$ , respectively, determine (a) the total amount of heat transfer to the copper ball, (b) the average rate of heat transfer to the ball, and (c) the average heat flux.

**SOLUTION** The copper ball is to be heated from  $100^\circ\text{C}$  to  $150^\circ\text{C}$ . The total heat transfer, the average rate of heat transfer, and the average heat flux are to be determined.

**Assumptions** Constant properties can be used for copper at the average temperature.

**Properties** The average density and specific heat of copper are given to be  $\rho = 8950 \text{ kg/m}^3$  and  $c_p = 0.395 \text{ kJ/kg}\cdot\text{C}$ .

**Analysis** (a) The amount of heat transferred to the copper ball is simply the change in its internal energy, and is determined from

Energy transfer to the system = Energy increase of the system

$$Q = \Delta U = mc_{\text{avg}}(T_2 - T_1)$$

where

$$m = \rho V = \frac{\pi}{6} \rho D^3 = \frac{\pi}{6} (8950 \text{ kg/m}^3)(0.1 \text{ m})^3 = 4.686 \text{ kg}$$

Substituting,

$$Q = (4.686 \text{ kg})(0.395 \text{ kJ/kg}\cdot\text{C})(150 - 100)^\circ\text{C} = \mathbf{92.6 \text{ kJ}}$$

Therefore, 92.6 kJ of heat needs to be transferred to the copper ball to heat it from  $100^\circ\text{C}$  to  $150^\circ\text{C}$ .

(b) The rate of heat transfer normally changes during a process with time. However, we can determine the *average* rate of heat transfer by dividing the total amount of heat transfer by the time interval. Therefore,

$$\dot{Q}_{\text{avg}} = \frac{Q}{\Delta t} = \frac{92.6 \text{ kJ}}{1800 \text{ s}} = 0.0514 \text{ kJ/s} = \mathbf{51.4 \text{ W}}$$

(c) Heat flux is defined as the heat transfer per unit time per unit area, or the rate of heat transfer per unit area. Therefore, the average heat flux in this case is

$$\dot{q}_{\text{avg}} = \frac{\dot{Q}_{\text{avg}}}{A} = \frac{\dot{Q}_{\text{avg}}}{\pi D^2} = \frac{51.4 \text{ W}}{\pi(0.1 \text{ m})^2} = 1636 \text{ W/m}^2$$

**Discussion** Note that heat flux may vary with location on a surface. The value calculated above is the *average* heat flux over the entire surface of the ball.

## 1–4 • THE FIRST LAW OF THERMODYNAMICS

The **first law of thermodynamics**, also known as the **conservation of energy principle**, states that *energy can neither be created nor destroyed during a process; it can only change forms*. Therefore, every bit of energy must be accounted for during a process. The conservation of energy principle (or the energy balance) for any system undergoing any process may be expressed as follows: *The net change (increase or decrease) in the total energy of the system during a process is equal to the difference between the total energy entering and the total energy leaving the system during that process*. That is

$$\left( \begin{array}{l} \text{Total energy} \\ \text{entering the} \\ \text{system} \end{array} \right) - \left( \begin{array}{l} \text{Total energy} \\ \text{leaving the} \\ \text{system} \end{array} \right) = \left( \begin{array}{l} \text{Change in the} \\ \text{total energy of} \\ \text{the system} \end{array} \right) \quad (1-9)$$

Noting that energy can be transferred to or from a system by *heat, work, and mass flow*, and that the total energy of a simple compressible system consists of internal, kinetic, and potential energies, the **energy balance** for any system undergoing any process can be expressed as

$$\underbrace{E_{\text{in}} - E_{\text{out}}}_{\substack{\text{Net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\Delta E_{\text{system}}}_{\substack{\text{Change in internal, kinetic,} \\ \text{potential, etc., energies}}} \quad (J) \quad (1-10)$$

or, in the **rate form**, as

$$\underbrace{\dot{E}_{\text{in}} - \dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer} \\ \text{by heat, work, and mass}}} = \underbrace{\frac{dE_{\text{system}}}{dt}}_{\substack{\text{Rate of change in internal,} \\ \text{kinetic, potential, etc., energies}}} \quad (W) \quad (1-11)$$

Energy is a property, and the value of a property does not change unless the state of the system changes. Therefore, the energy change of a system is zero ( $\Delta E_{\text{system}} = 0$ ) if the state of the system does not change during the process, that is, the process is steady. The energy balance in this case reduces to (Fig. 1–15)

$$\underbrace{\dot{E}_{\text{in}}}_{\substack{\text{Rate of net energy transfer in} \\ \text{by heat, work, and mass}}} = \underbrace{\dot{E}_{\text{out}}}_{\substack{\text{Rate of net energy transfer out} \\ \text{by heat, work, and mass}}} \quad (1-12)$$

In the absence of significant electric, magnetic, motion, gravity, and surface tension effects (i.e., for stationary simple compressible systems), the change

FIGURE 1–15

In steady operation, the rate of energy transfer to a system is equal to the rate of energy transfer from the system.

in the *total energy* of a system during a process is simply the change in its *internal energy*. That is,  $\Delta E_{\text{system}} = \Delta U_{\text{system}}$ .

In heat transfer analysis, we are usually interested only in the forms of energy that can be transferred as a result of a temperature difference, that is, heat or thermal energy. In such cases it is convenient to write a **heat balance** and to treat the conversion of nuclear, chemical, mechanical, and electrical energies into thermal energy as *heat generation*. The *energy balance* in that case can be expressed as

$$\underbrace{Q_{\text{in}} - Q_{\text{out}}}_{\text{Net heat transfer}} + \underbrace{E_{\text{gen}}}_{\text{Heat generation}} = \underbrace{\Delta E_{\text{thermal, system}}}_{\text{Change in thermal energy of the system}} \quad (\text{J}) \quad (1-13)$$

**FIGURE 1–16**

In the absence of any work interactions, the change in the energy content of a closed system is equal to the net heat transfer.

## Energy Balance for Closed Systems (Fixed Mass)

A closed system consists of a *fixed mass*. The total energy  $E$  for most systems encountered in practice consists of the internal energy  $U$ . This is especially the case for stationary systems since they don't involve any changes in their velocity or elevation during a process. The energy balance relation in that case reduces to

$$\text{Stationary closed system:} \quad E_{\text{in}} - E_{\text{out}} = \Delta U = mc_v\Delta T \quad (\text{J}) \quad (1-14)$$

where we expressed the internal energy change in terms of mass  $m$ , the specific heat at constant volume  $c_v$ , and the temperature change  $\Delta T$  of the system. When the system involves heat transfer only and no work interactions across its boundary, the energy balance relation further reduces to (Fig. 1–16)

$$\text{Stationary closed system, no work:} \quad Q = mc_v\Delta T \quad (\text{J}) \quad (1-15)$$

where  $Q$  is the net amount of heat transfer to or from the system. This is the form of the energy balance relation we will use most often when dealing with a fixed mass.

## Energy Balance for Steady-Flow Systems

A large number of engineering devices such as water heaters and car radiators involve mass flow in and out of a system, and are modeled as *control volumes*. Most control volumes are analyzed under steady operating conditions. The term *steady* means *no change with time* at a specified location. The opposite of steady is *unsteady* or *transient*. Also, the term *uniform* implies *no change with position* throughout a surface or region at a specified time. These meanings are consistent with their everyday usage (steady girlfriend, uniform distribution, etc.). The total energy content of a control volume during a *steady-flow process* remains constant ( $E_{\text{CV}} = \text{constant}$ ). That is, the change in the total energy of the control volume during such a process is zero ( $\Delta E_{\text{CV}} = 0$ ). Thus the amount of energy entering a control volume in all forms (heat, work, mass transfer) for a steady-flow process must be equal to the amount of energy leaving it.

The amount of mass flowing through a cross section of a flow device per unit time is called the **mass flow rate**, and is denoted by  $\dot{m}$ . A fluid may flow in and out of a control volume through pipes or ducts. The mass flow

rate of a fluid flowing in a pipe or duct is proportional to the cross-sectional area  $A_c$  of the pipe or duct, the density  $\rho$ , and the velocity  $V$  of the fluid. The mass flow rate through a differential area  $dA_c$  can be expressed as  $\delta\dot{m} = \rho V_n dA_c$  where  $V_n$  is the velocity component normal to  $dA_c$ . The mass flow rate through the entire cross-sectional area is obtained by integration over  $A_c$ .

The flow of a fluid through a pipe or duct can often be approximated to be *one-dimensional*. That is, the properties can be assumed to vary in one direction only (the direction of flow). As a result, all properties are assumed to be uniform at any cross section normal to the flow direction, and the properties are assumed to have *bulk average values* over the entire cross section. Under the one-dimensional flow approximation, the mass flow rate of a fluid flowing in a pipe or duct can be expressed as (Fig. 1–17)

$$\dot{m} = \rho V A_c \quad (\text{kg/s}) \quad (1-16)$$

where  $\rho$  is the fluid density,  $V$  is the average fluid velocity in the flow direction, and  $A_c$  is the cross-sectional area of the pipe or duct.

The volume of a fluid flowing through a pipe or duct per unit time is called the **volume flow rate**  $\dot{V}$ , and is expressed as

$$\dot{V} = V A_c = \frac{\dot{m}}{\rho} \quad (\text{m}^3/\text{s}) \quad (1-17)$$

Note that the mass flow rate of a fluid through a pipe or duct remains constant during steady flow. This is not the case for the volume flow rate, however, unless the density of the fluid remains constant.

For a steady-flow system with one inlet and one exit, the rate of mass flow into the control volume must be equal to the rate of mass flow out of it. That is,  $\dot{m}_{\text{in}} = \dot{m}_{\text{out}} = \dot{m}$ . When the changes in kinetic and potential energies are negligible, which is usually the case, and there is no work interaction, the energy balance for such a steady-flow system reduces to (Fig. 1–18)

$$\dot{Q} = \dot{m} \Delta h = \dot{m} c_p \Delta T \quad (\text{kJ/s}) \quad (1-18)$$

where  $\dot{Q}$  is the rate of net heat transfer into or out of the control volume. This is the form of the energy balance relation that we will use most often for steady-flow systems.

## Surface Energy Balance

As mentioned in the chapter opener, heat is transferred by the mechanisms of conduction, convection, and radiation, and heat often changes vehicles as it is transferred from one medium to another. For example, the heat conducted to the outer surface of the wall of a house in winter is convected away by the cold outdoor air while being radiated to the cold surroundings. In such cases, it may be necessary to keep track of the energy interactions at the surface, and this is done by applying the conservation of energy principle to the surface.

A surface contains no volume or mass, and thus no energy. Therefore, a surface can be viewed as a fictitious system whose energy content remains

**FIGURE 1–17**

The mass flow rate of a fluid at a cross section is equal to the product of the fluid density, average fluid velocity, and the cross-sectional area.

**FIGURE 1–18**

Under steady conditions, the net rate of energy transfer to a fluid in a control volume is equal to the rate of increase in the energy of the fluid stream flowing through the control volume.

**FIGURE 1-19**

Energy interactions at the outer wall surface of a house.

constant during a process (just like a steady-state or steady-flow system). Then the energy balance for a surface can be expressed as

$$\text{Surface energy balance: } \dot{E}_{\text{in}} = \dot{E}_{\text{out}} \quad (1-19)$$

This relation is valid for both steady and transient conditions, and the surface energy balance does not involve heat generation since a surface does not have a volume. The energy balance for the outer surface of the wall in Fig. 1-19, for example, can be expressed as

$$\dot{Q}_1 = \dot{Q}_2 + \dot{Q}_3 \quad (1-20)$$

where  $\dot{Q}_1$  is conduction through the wall to the surface,  $\dot{Q}_2$  is convection from the surface to the outdoor air, and  $\dot{Q}_3$  is net radiation from the surface to the surroundings.

When the directions of interactions are not known, all energy interactions can be assumed to be towards the surface, and the surface energy balance can be expressed as  $\sum \dot{E}_{\text{in}} = 0$ . Note that the interactions in opposite direction will end up having negative values, and balance this equation.

**FIGURE 1-20**

Schematic for Example 1-2.

### EXAMPLE 1-2 Cooling of Stainless Steel Sheets

A heated continuous AISI 304 stainless steel sheet is being conveyed at a constant speed of 1 cm/s into a chamber to be cooled (Fig. 1-20). The stainless steel sheet is 5 mm thick and 2 m wide, and it enters and exits the chamber at 500 K and 300 K, respectively. Determine the rate of heat loss from the stainless steel sheet inside the chamber.

**SOLUTION** The rate of heat loss from a stainless steel sheet being conveyed inside a chamber is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The stainless steel sheet has constant properties. 3 Changes in potential and kinetic energy are negligible.

**Properties** The constant pressure specific heat of AISI 304 stainless steel at the average temperature of  $(500 + 300)/2 = 400$  K is 515 J/kg·K. The density of AISI 304 stainless steel is 7900 kg/m<sup>3</sup> (Table A-3).

**Analysis** The mass of the stainless steel sheet being conveyed enters and exits the chamber at a rate of

$$\begin{aligned} \dot{m} &= \rho V w t \\ &= (7900 \text{ kg/m}^3)(0.01 \text{ m/s})(2 \text{ m})(0.005 \text{ m}) \\ &= 0.79 \text{ kg/s} \end{aligned}$$

The rate of heat loss from the stainless steel sheet in the chamber can be determined as

$$\begin{aligned} \dot{Q}_{\text{loss}} &= \dot{m} c_p (T_{\text{in}} - T_{\text{out}}) \\ &= (0.79 \text{ kg/s})(515 \text{ J/kg·K})(500 - 300) \text{ K} = 81370 \text{ J/s} \\ &= 81.4 \text{ kW} \end{aligned}$$

**Discussion** The stainless steel sheet being conveyed in and out of the chamber is treated as a control volume.

**EXAMPLE 1–3 Heat Loss from Heating Ducts in a Basement**

A 5-m-long section of an air heating system of a house passes through an unheated space in the basement (Fig. 1–21). The cross section of the rectangular duct of the heating system is 20 cm × 25 cm. Hot air enters the duct at 100 kPa and 60°C at an average velocity of 5 m/s. The temperature of the air in the duct drops to 54°C as a result of heat loss to the cool space in the basement. Determine the rate of heat loss from the air in the duct to the basement under steady conditions. Also, determine the cost of this heat loss per hour if the house is heated by a natural gas furnace that has an efficiency of 80 percent, and the cost of the natural gas in that area is \$1.60/therm (1 therm = 100,000 Btu = 105,500 kJ).

**SOLUTION** The temperature of the air in the heating duct of a house drops as a result of heat loss to the cool space in the basement. The rate of heat loss from the hot air and its cost are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Air can be treated as an ideal gas with constant properties at room temperature.

**Properties** The constant pressure specific heat of air at the average temperature of  $(54 + 60)/2 = 57^\circ\text{C}$  is 1.007 kJ/kg·K (Table A-15).

**Analysis** We take the basement section of the heating system as our system, which is a steady-flow system. The rate of heat loss from the air in the duct can be determined from

$$\dot{Q} = \dot{m}c_p\Delta T$$

where  $\dot{m}$  is the mass flow rate and  $\Delta T$  is the temperature drop. The density of air at the inlet conditions is

$$\rho = \frac{P}{RT} = \frac{100 \text{ kPa}}{(0.287 \text{ kPa}\cdot\text{m}^3/\text{kg}\cdot\text{K})(60 + 273)\text{K}} = 1.046 \text{ kg/m}^3$$

The cross-sectional area of the duct is

$$A_c = (0.20 \text{ m})(0.25 \text{ m}) = 0.05 \text{ m}^2$$

Then the mass flow rate of air through the duct and the rate of heat loss become

$$\dot{m} = \rho V A_c = (1.046 \text{ kg/m}^3)(5 \text{ m/s})(0.05 \text{ m}^2) = 0.2615 \text{ kg/s}$$

and

$$\begin{aligned}\dot{Q}_{\text{loss}} &= \dot{m}c_p(T_{\text{in}} - T_{\text{out}}) \\ &= (0.2615 \text{ kg/s})(1.007 \text{ kJ/kg}\cdot\text{°C})(60 - 54)\text{°C} \\ &= \mathbf{1.58 \text{ kJ/s}}\end{aligned}$$

**FIGURE 1–21**  
Schematic for Example 1–3.

or 5688 kJ/h. The cost of this heat loss to the home owner is

$$\begin{aligned}\text{Cost of heat loss} &= \frac{(\text{Rate of heat loss})(\text{Unit cost of energy input})}{\text{Furnace efficiency}} \\ &= \frac{(5688 \text{ kJ/h})(\$1.60/\text{therm})}{0.80} \left( \frac{1 \text{ therm}}{105,500 \text{ kJ}} \right) \\ &= \$0.108/\text{h}\end{aligned}$$

**Discussion** The heat loss from the heating ducts in the basement is costing the home owner 10.8 cents per hour. Assuming the heater operates 2000 hours during a heating season, the annual cost of this heat loss adds up to \$216. Most of this money can be saved by insulating the heating ducts in the unheated areas.

**FIGURE 1-22**

Schematic for Example 1-4.

### EXAMPLE 1-4 Electric Heating of a House at High Elevation

Consider a house that has a floor space of 2000 ft<sup>2</sup> and an average height of 9 ft at 5000 ft elevation where the standard atmospheric pressure is 12.2 psia (Fig. 1-22). Initially the house is at a uniform temperature of 50°F. Now the electric heater is turned on, and the heater runs until the air temperature in the house rises to an average value of 70°F. Determine the amount of energy transferred to the air assuming (a) the house is air-tight and thus no air escapes during the heating process and (b) some air escapes through the cracks as the heated air in the house expands at constant pressure. Also determine the cost of this heat for each case if the cost of electricity in that area is \$0.075/kWh.

**SOLUTION** The air in the house is heated by an electric heater. The amount and cost of the energy transferred to the air are to be determined for constant-volume and constant-pressure cases.

**Assumptions** 1 Air can be treated as an ideal gas with constant properties. 2 Heat loss from the house during heating is negligible. 3 The volume occupied by the furniture and other things is negligible.

**Properties** The specific heats of air at the average temperature of (50 + 70)/2 = 60°F are  $c_p = 0.240 \text{ Btu/lbm}\cdot\text{R}$  and  $c_v = c_p - R = 0.171 \text{ Btu/lbm}\cdot\text{R}$  (Tables A-1E and A-15E).

**Analysis** The volume and the mass of the air in the house are

$$V = (\text{Floor area})(\text{Height}) = (2000 \text{ ft}^2)(9 \text{ ft}) = 18,000 \text{ ft}^3$$

$$m = \frac{PV}{RT} = \frac{(12.2 \text{ psia})(18,000 \text{ ft}^3)}{(0.3704 \text{ psia}\cdot\text{ft}^3/\text{lbm}\cdot\text{R})(50 + 460)\text{R}} = 1162 \text{ lbm}$$

(a) The amount of energy transferred to air at constant volume is simply the change in its internal energy, and is determined from

$$\begin{aligned}E_{\text{in}} - E_{\text{out}} &= \Delta E_{\text{system}} \\ E_{\text{in, constant volume}} &= \Delta U_{\text{air}} = mc_v\Delta T \\ &= (1162 \text{ lbm})(0.171 \text{ Btu/lbm}\cdot\text{°F})(70 - 50)\text{°F} \\ &= 3974 \text{ Btu}\end{aligned}$$

At a unit cost of \$0.075/kWh, the total cost of this energy is

$$\begin{aligned}\text{Cost of energy} &= (\text{Amount of energy})(\text{Unit cost of energy}) \\ &= (3974 \text{ Btu})(\$0.075/\text{kWh})\left(\frac{1 \text{ kWh}}{3412 \text{ Btu}}\right) \\ &= \$\mathbf{0.087}\end{aligned}$$

(b) The amount of energy transferred to air at constant pressure is the change in its enthalpy, and is determined from

$$\begin{aligned}E_{\text{in, constant pressure}} &= \Delta H_{\text{air}} = mc_p\Delta T \\ &= (1162 \text{ lbm})(0.240 \text{ Btu/lbm}\cdot^{\circ}\text{F})(70 - 50)^{\circ}\text{F} \\ &= \mathbf{5578 \text{ Btu}}\end{aligned}$$

At a unit cost of \$0.075/kWh, the total cost of this energy is

$$\begin{aligned}\text{Cost of energy} &= (\text{Amount of energy})(\text{Unit cost of energy}) \\ &= (5578 \text{ Btu})(\$0.075/\text{kWh})\left(\frac{1 \text{ kWh}}{3412 \text{ Btu}}\right) \\ &= \$\mathbf{0.123}\end{aligned}$$

**Discussion** It costs about 9 cents in the first case and 12 cents in the second case to raise the temperature of the air in this house from 50°F to 70°F. The second answer is more realistic since every house has cracks, especially around the doors and windows, and the pressure in the house remains essentially constant during a heating process. Therefore, the second approach is used in practice. This conservative approach somewhat overpredicts the amount of energy used, however, since some of the air escapes through the cracks before it is heated to 70°F.

## 1–5 ▪ HEAT TRANSFER MECHANISMS

In Section 1–1, we defined *heat* as the form of energy that can be transferred from one system to another as a result of temperature difference. A thermodynamic analysis is concerned with the *amount* of heat transfer as a system undergoes a process from one equilibrium state to another. The science that deals with the determination of the *rates* of such energy transfers is the *heat transfer*. The transfer of energy as heat is always from the higher-temperature medium to the lower-temperature one, and heat transfer stops when the two mediums reach the same temperature.

Heat can be transferred in three different modes: *conduction*, *convection*, and *radiation*. All modes of heat transfer require the existence of a temperature difference, and all modes are from the high-temperature medium to a lower-temperature one. Below we give a brief description of each mode. A detailed study of these modes is given in later chapters of this text.

## 1–6 ▪ CONDUCTION

**Conduction** is the transfer of energy from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between the particles. Conduction can take place in solids, liquids, or gases.

**FIGURE 1–23**

Heat conduction through a large plane wall of thickness  $\Delta x$  and area  $A$ .

In gases and liquids, conduction is due to the *collisions* and *diffusion* of the molecules during their random motion. In solids, it is due to the combination of *vibrations* of the molecules in a lattice and the energy transport by *free electrons*. A cold canned drink in a warm room, for example, eventually warms up to the room temperature as a result of heat transfer from the room to the drink through the aluminum can by conduction.

The *rate* of heat conduction through a medium depends on the *geometry* of the medium, its *thickness*, and the *material* of the medium, as well as the *temperature difference* across the medium. We know that wrapping a hot water tank with glass wool (an insulating material) reduces the rate of heat loss from the tank. The thicker the insulation, the smaller the heat loss. We also know that a hot water tank loses heat at a higher rate when the temperature of the room housing the tank is lowered. Further, the larger the tank, the larger the surface area and thus the rate of heat loss.

Consider steady heat conduction through a large plane wall of thickness  $\Delta x = L$  and area  $A$ , as shown in Fig. 1–23. The temperature difference across the wall is  $\Delta T = T_2 - T_1$ . Experiments have shown that the rate of heat transfer  $\dot{Q}$  through the wall is *doubled* when the temperature difference  $\Delta T$  across the wall or the area  $A$  normal to the direction of heat transfer is doubled, but is *halved* when the wall thickness  $L$  is doubled. Thus we conclude that *the rate of heat conduction through a plane layer is proportional to the temperature difference across the layer and the heat transfer area, but is inversely proportional to the thickness of the layer*. That is,

$$\text{Rate of heat conduction} \propto \frac{\text{(Area)}(\text{Temperature difference})}{\text{Thickness}}$$

or,

$$\dot{Q}_{\text{cond}} = kA \frac{T_1 - T_2}{\Delta x} = -kA \frac{\Delta T}{\Delta x} \quad (\text{W}) \quad (1-21)$$

where the constant of proportionality  $k$  is the **thermal conductivity** of the material, which is a *measure of the ability of a material to conduct heat* (Fig. 1–24). In the limiting case of  $\Delta x \rightarrow 0$ , the equation above reduces to the differential form

$$\dot{Q}_{\text{cond}} = -kA \frac{dT}{dx} \quad (\text{W}) \quad (1-22)$$

which is called **Fourier's law of heat conduction** after J. Fourier (Fig. 1–25), who expressed it first in his heat transfer text in 1822. Here  $dT/dx$  is the **temperature gradient**, which is the slope of the temperature curve on a  $T$ - $x$  diagram (the rate of change of  $T$  with  $x$ ), at location  $x$ . The relation above indicates that the rate of heat conduction in a given direction is proportional to the temperature gradient in that direction. Heat is conducted in the direction of decreasing temperature, and the temperature gradient becomes negative when temperature decreases with increasing  $x$ . The *negative sign* in Eq. 1–22 ensures that heat transfer in the positive  $x$  direction is a positive quantity.

The heat transfer area  $A$  is always *normal* to the direction of heat transfer. For heat loss through a 5-m-long, 3-m-high, and 25-cm-thick wall, for example, the heat transfer area is  $A = 15 \text{ m}^2$ . Note that the thickness of the wall has no effect on  $A$  (Fig. 1–26).

(a) Copper ( $k = 401 \text{ W/m}\cdot\text{K}$ )(b) Silicon ( $k = 148 \text{ W/m}\cdot\text{K}$ )**FIGURE 1–24**

The rate of heat conduction through a solid is directly proportional to its thermal conductivity.

**EXAMPLE 1–5** The Cost of Heat Loss through a Roof

The roof of an electrically heated home is 6 m long, 8 m wide, and 0.25 m thick, and is made of a flat layer of concrete whose thermal conductivity is  $k = 0.8 \text{ W/m}\cdot\text{K}$  (Fig. 1–27). The temperatures of the inner and the outer surfaces of the roof one night are measured to be 15°C and 4°C, respectively, for a period of 10 hours. Determine (a) the rate of heat loss through the roof that night and (b) the cost of that heat loss to the home owner if the cost of electricity is \$0.08/kWh.

**SOLUTION** The inner and outer surfaces of the flat concrete roof of an electrically heated home are maintained at specified temperatures during a night. The heat loss through the roof and its cost that night are to be determined.

**Assumptions** 1 Steady operating conditions exist during the entire night since the surface temperatures of the roof remain constant at the specified values. 2 Constant properties can be used for the roof.

**Properties** The thermal conductivity of the roof is given to be  $k = 0.8 \text{ W/m}\cdot\text{K}$ .

**Analysis** (a) Noting that heat transfer through the roof is by conduction and the area of the roof is  $A = 6 \text{ m} \times 8 \text{ m} = 48 \text{ m}^2$ , the steady rate of heat transfer through the roof is

$$\dot{Q} = kA \frac{T_1 - T_2}{L} = (0.8 \text{ K})(48 \text{ m}^2) \frac{(15 - 4)^\circ\text{C}}{0.25 \text{ m}} = 1690 \text{ W} = 1.69 \text{ kW}$$

(b) The amount of heat lost through the roof during a 10-hour period and its cost is

$$Q = \dot{Q} \Delta t = (1.69 \text{ kW})(10 \text{ h}) = 16.9 \text{ kWh}$$

$$\begin{aligned} \text{Cost} &= (\text{Amount of energy})(\text{Unit cost of energy}) \\ &= (16.9 \text{ kWh})(\$0.08/\text{kWh}) = \$1.35 \end{aligned}$$

**Discussion** The cost to the home owner of the heat loss through the roof that night was \$1.35. The total heating bill of the house will be much larger since the heat losses through the walls are not considered in these calculations.

**FIGURE 1–25**

**Jean Baptiste Joseph Fourier** (1768–1830) was a French mathematician and physicist born in Auxerre, France. He is best known for his work on the infinite series of trigonometric functions that bear his name and for his development of the mathematical theory of heat conduction. Fourier established the partial differential equation governing heat diffusion, and he solved it by using the Fourier series. The Fourier transform, Fourier number, and the Fourier's law of heat conduction are named in his honor. Fourier is also credited with the discovery of the phenomenon of greenhouse effect in 1824.

**Thermal Conductivity**

We have seen that different materials store heat differently, and we have defined the property specific heat  $c_p$  as a measure of a material's ability to store thermal energy. For example,  $c_p = 4.18 \text{ kJ/kg}\cdot^\circ\text{C}$  for water and  $c_p = 0.45 \text{ kJ/kg}\cdot^\circ\text{C}$  for iron at room temperature, which indicates that water can store almost 10 times the energy that iron can per unit mass. Likewise, the thermal conductivity  $k$  is a measure of a material's ability to conduct heat. For example,  $k = 0.607 \text{ W/m}\cdot\text{K}$  for water and  $k = 80.2 \text{ W/m}\cdot\text{K}$  for iron at room temperature, which indicates that iron conducts heat more than 100 times faster than water can. Thus we say that water is a poor heat conductor relative to iron, although water is an excellent medium to store thermal energy.

Equation 1–21 for the rate of conduction heat transfer under steady conditions can also be viewed as the defining equation for thermal conductivity. Thus the **thermal conductivity** of a material can be defined as *the rate of*

**FIGURE 1–26**

In heat conduction analysis,  $A$  represents the area *normal* to the direction of heat transfer.

**FIGURE 1–27**

Schematic for Example 1–5.

**TABLE 1–1**

The thermal conductivities of some materials at room temperature

| Material             | $k$ , W/m·K* |
|----------------------|--------------|
| Diamond              | 2300         |
| Silver               | 429          |
| Copper               | 401          |
| Gold                 | 317          |
| Aluminum             | 237          |
| Iron                 | 80.2         |
| Mercury (l)          | 8.54         |
| Glass                | 0.78         |
| Brick                | 0.72         |
| Water (l)            | 0.607        |
| Human skin           | 0.37         |
| Wood (oak)           | 0.17         |

| Urethane, rigid foam | 0.026        |

\*Multiply by 0.5778 to convert to Btu/h·ft·°F.

heat transfer through a unit thickness of the material per unit area per unit temperature difference. The thermal conductivity of a material is a measure of the ability of the material to conduct heat. A high value for thermal conductivity indicates that the material is a good heat conductor, and a low value indicates that the material is a poor heat conductor or *insulator*. The thermal conductivities of some common materials at room temperature are given in Table 1–1. The thermal conductivity of pure copper at room temperature is  $k = 401 \text{ W/m}\cdot\text{K}$ , which indicates that a 1-m-thick copper wall will conduct heat at a rate of 401 W per  $\text{m}^2$  area per K temperature difference across the wall. Note that materials such as copper and silver that are good electric conductors are also good heat conductors, and have high values of thermal conductivity. Materials such as rubber, wood, and Styrofoam are poor conductors of heat and have low conductivity values.

A layer of material of known thickness and area can be heated from one side by an electric resistance heater of known output. If the outer surfaces of the heater are well insulated, all the heat generated by the resistance heater will be transferred through the material whose conductivity is to be determined. Then measuring the two surface temperatures of the material when steady heat transfer is reached and substituting them into Eq. 1–21 together with other known quantities give the thermal conductivity (Fig. 1–28).

The thermal conductivities of materials vary over a wide range, as shown in Fig. 1–29. The thermal conductivities of gases such as air vary by a factor of  $10^4$  from those of pure metals such as copper. Note that pure crystals and metals have the highest thermal conductivities, and gases and insulating materials the lowest.

Temperature is a measure of the kinetic energies of the particles such as the molecules or atoms of a substance. In a liquid or gas, the kinetic energy of the molecules is due to their random translational motion as well as their vibrational and rotational motions. When two molecules possessing different kinetic energies collide, part of the kinetic energy of the more energetic (higher-temperature) molecule is transferred to the less energetic (lower-temperature) molecule, much the same as when two elastic balls of the same mass at different velocities collide, part of the kinetic energy of the faster ball is transferred to the slower one. The higher the temperature, the faster the molecules move and the higher the number of such collisions, and the better the heat transfer.

The *kinetic theory* of gases predicts and the experiments confirm that the thermal conductivity of gases is proportional to the *square root of the thermodynamic temperature  $T$* , and inversely proportional to the *square root of the molar mass  $M$* . Therefore, for a particular gas (fixed  $M$ ), the thermal conductivity increases with increasing temperature and at a fixed temperature the thermal conductivity decreases with increasing  $M$ . For example, at a fixed temperature of 1000 K, the thermal conductivity of helium ( $M = 4$ ) is 0.343 W/m·K and that of air ( $M = 29$ ) is 0.0667 W/m·K, which is much lower than that of helium.

The thermal conductivities of *gases* at 1 atm pressure are listed in Table A-16. However, they can also be used at pressures other than 1 atm, since the thermal conductivity of gases is *independent of pressure* in a wide range of pressures encountered in practice.

The mechanism of heat conduction in a *liquid* is complicated by the fact that the molecules are more closely spaced, and they exert a stronger intermolecular force field. The thermal conductivities of liquids usually lie between those of

solids and gases. The thermal conductivity of a substance is normally highest in the solid phase and lowest in the gas phase. The thermal conductivity of liquids is generally insensitive to pressure except near the thermodynamic critical point. Unlike gases, the thermal conductivities of most liquids decrease with increasing temperature, with water being a notable exception. Like gases, the conductivity of liquids decreases with increasing molar mass. Liquid metals such as mercury and sodium have high thermal conductivities and are very suitable for use in applications where a high heat transfer rate to a liquid is desired, as in nuclear power plants.

In *solids*, heat conduction is due to two effects: the *lattice vibrational waves* induced by the vibrational motions of the molecules positioned at relatively fixed positions in a periodic manner called a lattice, and the energy transported via the *free flow of electrons* in the solid (Fig. 1–30). The thermal conductivity of a solid is obtained by adding the lattice and electronic components. The relatively high thermal conductivities of pure metals are primarily due to the electronic component. The lattice component of thermal conductivity strongly depends on the way the molecules are arranged. For example, diamond, which is a highly ordered crystalline solid, has the highest known thermal conductivity at room temperature.

Unlike metals, which are good electrical and heat conductors, *crystalline solids* such as diamond and semiconductors such as silicon are good heat conductors but poor electrical conductors. As a result, such materials find

**TABLE 1-2**

The thermal conductivity of an alloy is usually much lower than the thermal conductivity of either metal of which it is composed

| Pure metal or alloy                          | $k$ , W/m·K,<br>at 300 K |
|--|--------------------------|
| Copper                                       | 401                      |
| Nickel                                       | 91                       |
| <i>Constantan</i><br>(55% Cu, 45% Ni)        | 23                       |
| Copper                                       | 401                      |
| Aluminum                                     | 237                      |
| <i>Commercial bronze</i><br>(90% Cu, 10% Al) | 52                       |

widespread use in the electronics industry. Despite their higher price, diamond heat sinks are used in the cooling of sensitive electronic components because of the excellent thermal conductivity of diamond. Silicon oils and gaskets are commonly used in the packaging of electronic components because they provide both good thermal contact and good electrical insulation.

Pure metals have high thermal conductivities, and one would think that *metal alloys* should also have high conductivities. One would expect an alloy made of two metals of thermal conductivities  $k_1$  and  $k_2$  to have a conductivity  $k$  between  $k_1$  and  $k_2$ . But this turns out not to be the case. The thermal conductivity of an alloy of two metals is usually much lower than that of either metal, as shown in Table 1-2. Even small amounts in a pure metal of “foreign” molecules that are good conductors themselves seriously disrupt the transfer of heat in that metal. For example, the thermal conductivity of steel containing just 1 percent of chrome is 62 W/m·K, while the thermal conductivities of iron and chromium are 83 and 95 W/m·K, respectively.

The thermal conductivities of materials vary with temperature (Table 1-3). The variation of thermal conductivity over certain temperature ranges is negligible for some materials, but significant for others, as shown in Fig. 1-31. The thermal conductivities of certain solids exhibit dramatic increases at temperatures near absolute zero, when these solids become *superconductors*. For example, the conductivity of copper reaches a maximum value of about 20,000 W/m·K at 20 K, which is about 50 times the conductivity at room temperature. The thermal conductivities and other thermal properties of various materials are given in Tables A-3 to A-17.

Values of thermal conductivity given in Tables A-3 to A-17 are appropriate when the physical dimensions of the material under consideration are relatively large. In some of the emerging areas of technology, such as microelectronics, the physical dimensions are typically in the order of micro or nano meters. For these applications the small physical dimensions most likely will influence the value of thermal conductivity in the solid and liquid states. In these situations, as the physical dimensions decrease, the average net distance traveled by the energy carriers typically decreases and this reduces the value of thermal conductivity.

The temperature dependence of thermal conductivity causes considerable complexity in conduction analysis. Therefore, it is common practice to evaluate the thermal conductivity  $k$  at the *average temperature* and treat it as a *constant* in calculations.

In heat transfer analysis, a material is normally assumed to be *isotropic*; that is, to have uniform properties in all directions. This assumption is realistic for most materials, except those that exhibit different structural characteristics in different directions, such as laminated composite materials and wood. The thermal conductivity of wood across the grain, for example, is different than that parallel to the grain.

## Thermal Diffusivity

The product  $\rho c_p$ , which is frequently encountered in heat transfer analysis, is called the **heat capacity** of a material. Both the specific heat  $c_p$  and the heat capacity  $\rho c_p$  represent the heat storage capability of a material. But  $c_p$  expresses it *per unit mass* whereas  $\rho c_p$  expresses it *per unit volume*, as can be noticed from their units J/kg·K and J/m<sup>3</sup>·K, respectively.

**TABLE 1–3**

Thermal conductivities of materials vary with temperature

| T, K | k, W/m·K |          |
|------|----------|----------|
|      | Copper   | Aluminum |
| 100  | 482      | 302      |
| 200  | 413      | 237      |
| 300  | 401      | 237      |
| 400  | 393      | 240      |
| 600  | 379      | 231      |
| 800  | 366      | 218      |

**FIGURE 1–31**

The variation of the thermal conductivity of various solids, liquids, and gases with temperature.

Another material property that appears in the transient heat conduction analysis is the **thermal diffusivity**, which represents how fast heat diffuses through a material and is defined as

$$\alpha = \frac{\text{Heat conduction}}{\text{Heat storage}} = \frac{k}{\rho c_p} \quad (\text{m}^2/\text{s}) \quad (1-23)$$

Note that the thermal conductivity  $k$  represents how well a material conducts heat, and the heat capacity  $\rho c_p$  represents how much energy a material stores per unit volume. Therefore, the thermal diffusivity of a material can be viewed as the ratio of the *heat conducted* through the material to the *heat stored* per unit volume. A material that has a high thermal conductivity or a low heat capacity will obviously have a large thermal diffusivity. The larger the thermal diffusivity, the faster the propagation of heat into the medium. A small value of thermal diffusivity means that heat is mostly absorbed by the material and a small amount of heat is conducted further.

The thermal diffusivities of some common materials at 20°C are given in Table 1–4. Note that the thermal diffusivity ranges from  $\alpha = 0.14 \times 10^{-6}$  m<sup>2</sup>/s for water to  $149 \times 10^{-6}$  m<sup>2</sup>/s for silver, which is a difference of more than a thousand times. Also note that the thermal diffusivities of beef and water are the same. This is not surprising, since meat as well as fresh vegetables and fruits are mostly water, and thus they possess the thermal properties of water.

**TABLE 1–4**

The thermal diffusivities of some materials at room temperature

| Material         | $\alpha$ , m <sup>2</sup> /s* |
|------------------|-------------------------------|
| Silver           | $149 \times 10^{-6}$          |
| Gold             | $127 \times 10^{-6}$          |
| Copper           | $113 \times 10^{-6}$          |
| Aluminum         | $97.5 \times 10^{-6}$         |
| Iron             | $22.8 \times 10^{-6}$         |
| Mercury (l)      | $4.7 \times 10^{-6}$          |
| Marble           | $1.2 \times 10^{-6}$          |
| Ice              | $1.2 \times 10^{-6}$          |
| Concrete         | $0.75 \times 10^{-6}$         |
| Brick            | $0.52 \times 10^{-6}$         |
| Heavy soil (dry) | $0.52 \times 10^{-6}$         |
| Glass            | $0.34 \times 10^{-6}$         |
| Glass wool       | $0.23 \times 10^{-6}$         |
| Water (l)        | $0.14 \times 10^{-6}$         |
| Beef             | $0.14 \times 10^{-6}$         |
| Wood (oak)       | $0.13 \times 10^{-6}$         |

\*Multiply by 10.76 to convert to ft<sup>2</sup>/s.

**FIGURE 1-32**

Apparatus to measure the thermal conductivity of a material using two identical samples and a thin resistance heater (Example 1-6).

### EXAMPLE 1-6 Measuring the Thermal Conductivity of a Material

A common way of measuring the thermal conductivity of a material is to sandwich an electric thermofoil heater between two identical samples of the material, as shown in Fig. 1-32. The thickness of the resistance heater, including its cover, which is made of thin silicon rubber, is usually less than 0.5 mm. A circulating fluid such as tap water keeps the exposed ends of the samples at constant temperature. The lateral surfaces of the samples are well insulated to ensure that heat transfer through the samples is one-dimensional. Two thermocouples are embedded into each sample some distance  $L$  apart, and a differential thermometer reads the temperature drop  $\Delta T$  across this distance along each sample. When steady operating conditions are reached, the total rate of heat transfer through both samples becomes equal to the electric power drawn by the heater.

In a certain experiment, cylindrical samples of diameter 5 cm and length 10 cm are used. The two thermocouples in each sample are placed 3 cm apart. After initial transients, the electric heater is observed to draw 0.4 A at 110 V, and both differential thermometers read a temperature difference of 15°C. Determine the thermal conductivity of the sample.

**SOLUTION** The thermal conductivity of a material is to be determined by ensuring one-dimensional heat conduction, and by measuring temperatures when steady operating conditions are reached.

**Assumptions** 1 Steady operating conditions exist since the temperature readings do not change with time. 2 Heat losses through the lateral surfaces of the apparatus are negligible since those surfaces are well insulated, and thus the entire heat generated by the heater is conducted through the samples. 3 The apparatus possesses thermal symmetry.

**Analysis** The electrical power consumed by the resistance heater and converted to heat is

$$\dot{W}_e = VI = (110 \text{ V})(0.4 \text{ A}) = 44 \text{ W}$$

The rate of heat flow through each sample is

$$\dot{Q} = \frac{1}{2} \dot{W}_e = \frac{1}{2} \times (44 \text{ W}) = 22 \text{ W}$$

since only half of the heat generated flows through each sample because of symmetry. Reading the same temperature difference across the same distance in each sample also confirms that the apparatus possesses thermal symmetry. The heat transfer area is the area normal to the direction of heat transfer, which is the cross-sectional area of the cylinder in this case:

$$A = \frac{1}{4} \pi D^2 = \frac{1}{4} \pi (0.05 \text{ m})^2 = 0.001963 \text{ m}^2$$

Noting that the temperature drops by 15°C within 3 cm in the direction of heat flow, the thermal conductivity of the sample is determined to be

$$\dot{Q} = kA \frac{\Delta T}{L} \rightarrow k = \frac{\dot{Q} L}{A \Delta T} = \frac{(22 \text{ W})(0.03 \text{ m})}{(0.001963 \text{ m}^2)(15^\circ\text{C})} = 22.4 \text{ W/m}\cdot\text{K}$$

**Discussion** Perhaps you are wondering if we really need to use two samples in the apparatus, since the measurements on the second sample do not give any additional information. It seems like we can replace the second sample by insulation. Indeed, we do not need the second sample; however, it enables us to verify the temperature measurements on the first sample and provides thermal symmetry, which reduces experimental error.

**EXAMPLE 1–7** Conversion between SI and English Units

An engineer who is working on the heat transfer analysis of a brick building in English units needs the thermal conductivity of brick. But the only value he can find from his handbooks is 0.72 W/m·°C, which is in SI units. To make matters worse, the engineer does not have a direct conversion factor between the two unit systems for thermal conductivity. Can you help him out?

**SOLUTION** The situation this engineer is facing is not unique, and most engineers often find themselves in a similar position. A person must be very careful during unit conversion not to fall into some common pitfalls and to avoid some costly mistakes. Although unit conversion is a simple process, it requires utmost care and careful reasoning.

The conversion factors for W and m are straightforward and are given in conversion tables to be

$$1 \text{ W} = 3.41214 \text{ Btu/h}$$

$$1 \text{ m} = 3.2808 \text{ ft}$$

But the conversion of °C into °F is not so simple, and it can be a source of error if one is not careful. Perhaps the first thought that comes to mind is to replace °C by  $(^{\circ}\text{F} - 32)/1.8$  since  $T(^{\circ}\text{C}) = [T(^{\circ}\text{F}) - 32]/1.8$ . But this will be wrong since the °C in the unit W/m·°C represents *per °C change in temperature*. Noting that 1°C change in temperature corresponds to 1.8°F, the proper conversion factor to be used is

$$1^{\circ}\text{C} = 1.8^{\circ}\text{F}$$

Substituting, we get

$$1 \text{ W/m} \cdot ^{\circ}\text{C} = \frac{3.41214 \text{ Btu/h}}{(3.2808 \text{ ft})(1.8^{\circ}\text{F})} = 0.5778 \text{ Btu/h} \cdot \text{ft} \cdot ^{\circ}\text{F}$$

which is the desired conversion factor. Therefore, the thermal conductivity of the brick in English units is

$$\begin{aligned} k_{\text{brick}} &= 0.72 \text{ W/m} \cdot ^{\circ}\text{C} \\ &= 0.72 \times (0.5778 \text{ Btu/h} \cdot \text{ft} \cdot ^{\circ}\text{F}) \\ &= \mathbf{0.42 \text{ Btu/h} \cdot \text{ft} \cdot ^{\circ}\text{F}} \end{aligned}$$

**Discussion** Note that the thermal conductivity value of a material in English units is about half that in SI units (Fig. 1–33). Also note that we rounded the result to two significant digits (the same number in the original value) since expressing the result in more significant digits (such as 0.4160 instead of 0.42) would falsely imply a more accurate value than the original one.

$$\begin{aligned} k &= 0.72 \text{ W/m} \cdot ^{\circ}\text{C} \\ &= 0.42 \text{ Btu/h} \cdot \text{ft} \cdot ^{\circ}\text{F} \end{aligned}$$

**FIGURE 1–33**

The thermal conductivity value in English units is obtained by multiplying the value in SI units by 0.5778.

## 1–7 • CONVECTION

**Convection** is the mode of energy transfer between a solid surface and the adjacent liquid or gas that is in motion, and it involves the combined effects of *conduction* and *fluid motion*. The faster the fluid motion, the greater the convection heat transfer. In the absence of any bulk fluid motion, heat transfer between a solid surface and the adjacent fluid is by pure conduction. The presence of bulk motion of the fluid enhances the heat transfer between the solid surface and the fluid, but it also complicates the determination of heat transfer rates.

FIGURE 1-34

Heat transfer from a hot surface to air by convection.

FIGURE 1-35

The cooling of a boiled egg by forced and natural convection.

TABLE 1-5

Typical values of convection heat transfer coefficient

| Type of convection           | $h, \text{W/m}^2\cdot\text{K}^*$ |
|------------------------------|----------------------------------|
| Free convection of gases     | 2–25                             |
| Free convection of liquids   | 10–1000                          |
| Forced convection of gases   | 25–250                           |
| Forced convection of liquids | 50–20,000                        |
| Boiling and condensation     | 2500–100,000                     |

\*Multiply by 0.176 to convert to  $\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ .

Consider the cooling of a hot block by blowing cool air over its top surface (Fig. 1-34). Heat is first transferred to the air layer adjacent to the block by conduction. This heat is then carried away from the surface by convection, that is, by the combined effects of conduction within the air that is due to random motion of air molecules and the bulk or macroscopic motion of the air that removes the heated air near the surface and replaces it by the cooler air.

Convection is called **forced convection** if the fluid is forced to flow over the surface by external means such as a fan, pump, or the wind. In contrast, convection is called **natural (or free) convection** if the fluid motion is caused by buoyancy forces that are induced by density differences due to the variation of temperature in the fluid (Fig. 1-35). For example, in the absence of a fan, heat transfer from the surface of the hot block in Fig. 1-34 is by natural convection since any motion in the air in this case is due to the rise of the warmer (and thus lighter) air near the surface and the fall of the cooler (and thus heavier) air to fill its place. Heat transfer between the block and the surrounding air is by conduction if the temperature difference between the air and the block is not large enough to overcome the resistance of air to movement and thus to initiate natural convection currents.

Heat transfer processes that involve *change of phase* of a fluid are also considered to be convection because of the fluid motion induced during the process, such as the rise of the vapor bubbles during boiling or the fall of the liquid droplets during condensation.

Despite the complexity of convection, the rate of *convection heat transfer* is observed to be proportional to the temperature difference, and is conveniently expressed by **Newton's law of cooling** as (Fig. 1-36)

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) \quad (\text{W}) \quad (1-24)$$

where  $h$  is the *convection heat transfer coefficient* in  $\text{W/m}^2\cdot\text{K}$  or  $\text{Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$ ,  $A_s$  is the surface area through which convection heat transfer takes place,  $T_s$  is the surface temperature, and  $T_\infty$  is the temperature of the fluid sufficiently far from the surface. Note that at the surface, the fluid temperature equals the surface temperature of the solid.

The convection heat transfer coefficient  $h$  is not a property of the fluid. It is an experimentally determined parameter whose value depends on all the variables influencing convection such as the surface geometry, the nature of fluid motion, the properties of the fluid, and the bulk fluid velocity. Typical values of  $h$  are given in Table 1-5.

Some people do not consider convection to be a fundamental mechanism of heat transfer since it is essentially heat conduction in the presence of fluid motion. But we still need to give this combined phenomenon a name, unless we are willing to keep referring to it as "conduction with fluid motion." Thus, it is practical to recognize convection as a separate heat transfer mechanism despite the valid arguments to the contrary.

#### EXAMPLE 1-8 Measuring Convection Heat Transfer Coefficient

A 2-m-long, 0.3-cm-diameter electrical wire extends across a room at  $15^\circ\text{C}$ , as shown in Fig. 1-37. Heat is generated in the wire as a result of resistance heating, and the surface temperature of the wire is measured to be  $152^\circ\text{C}$  in

steady operation. Also, the voltage drop and electric current through the wire are measured to be 60 V and 1.5 A, respectively. Disregarding any heat transfer by radiation, determine the convection heat transfer coefficient for heat transfer between the outer surface of the wire and the air in the room.

**SOLUTION** The convection heat transfer coefficient for heat transfer from an electrically heated wire to air is to be determined by measuring temperatures when steady operating conditions are reached and the electric power consumed.

**Assumptions** 1 Steady operating conditions exist since the temperature readings do not change with time. 2 Radiation heat transfer is negligible.

**Analysis** When steady operating conditions are reached, the rate of heat loss from the wire equals the rate of heat generation in the wire as a result of resistance heating. That is,

$$\dot{Q} = \dot{E}_{\text{generated}} = \mathbf{VI} = (60 \text{ V})(1.5 \text{ A}) = 90 \text{ W}$$

The surface area of the wire is

$$A_s = \pi DL = \pi(0.003 \text{ m})(2 \text{ m}) = 0.01885 \text{ m}^2$$

Newton's law of cooling for convection heat transfer is expressed as

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty)$$

Disregarding any heat transfer by radiation and thus assuming all the heat loss from the wire to occur by convection, the convection heat transfer coefficient is determined to be

$$h = \frac{\dot{Q}_{\text{conv}}}{A_s(T_s - T_\infty)} = \frac{90 \text{ W}}{(0.01885 \text{ m}^2)(152 - 15)^\circ\text{C}} = 34.9 \text{ W/m}^2\cdot\text{K}$$

**Discussion** Note that the simple setup described above can be used to determine the average heat transfer coefficients from a variety of surfaces in air. Also, heat transfer by radiation can be eliminated by keeping the surrounding surfaces at the temperature of the wire.

FIGURE 1–36

**Sir Isaac Newton** (1642–1727) was an English mathematician, physicist, and astronomer, born in Lincolnshire, England. Newton is regarded as one of the greatest scientists and mathematicians in history. His contributions to mathematics include the development of the binomial theorem, the differential calculus, and the integral calculus. He is said to have conceived the idea of the law of gravity upon the observation of the fall of an apple in 1665. With the three fundamental laws that bear his name and are described in *Philosophiae Naturalis Principia Mathematica*, Newton is known as the father of classical mechanics. Newton showed that each of Kepler's three laws on the motion of planets and stars could be derived from the single law of gravity. Newton is also credited for the discovery of the composite nature of white light and the separation of different colors by a prism. The law of cooling that governs the rate of heat transfer from a hot surface to a cooler surrounding fluid is also attributed to Newton.

## 1–8 ■ RADIATION

**Radiation** is the energy emitted by matter in the form of *electromagnetic waves* (or *photons*) as a result of the changes in the electronic configurations of the atoms or molecules. Unlike conduction and convection, the transfer of heat by radiation does not require the presence of an *intervening medium*. In fact, heat transfer by radiation is fastest (at the speed of light) and it suffers no attenuation in a vacuum. This is how the energy of the sun reaches the earth.

In heat transfer studies we are interested in *thermal radiation*, which is the form of radiation emitted by bodies because of their temperature. It differs from other forms of electromagnetic radiation such as x-rays, gamma rays, microwaves, radio waves, and television waves that are not related to temperature. All bodies at a temperature above absolute zero emit thermal radiation.

Radiation is a *volumetric phenomenon*, and all solids, liquids, and gases emit, absorb, or transmit radiation to varying degrees. However, radiation is

**FIGURE 1–38**

Blackbody radiation represents the *maximum amount of radiation that can be emitted from a surface at a specified temperature.*

**TABLE 1–6**

Emissivities of some materials at 300 K

| Material                 | Emissivity |
|--------------------------|------------|
| Aluminum foil            | 0.07       |
| Anodized aluminum        | 0.82       |
| Polished copper          | 0.03       |
| Polished gold            | 0.03       |
| Polished silver          | 0.02       |
| Polished stainless steel | 0.17       |
| Black paint              | 0.98       |
| White paint              | 0.90       |
| White paper              | 0.92–0.97  |
| Asphalt pavement         | 0.85–0.93  |
| Red brick                | 0.93–0.96  |
| Human skin               | 0.95       |
| Wood                     | 0.82–0.92  |
| Soil                     | 0.93–0.96  |
| Water                    | 0.96       |
| Vegetation               | 0.92–0.96  |

usually considered to be a *surface phenomenon* for solids that are opaque to thermal radiation such as metals, wood, and rocks since the radiation emitted by the interior regions of such material can never reach the surface, and the radiation incident on such bodies is usually absorbed within a few microns from the surface.

The maximum rate of radiation that can be emitted from a surface at a thermodynamic temperature  $T_s$  (in K or R) is given by the **Stefan–Boltzmann law** as

$$\dot{Q}_{\text{emit, max}} = \sigma A_s T_s^4 \quad (\text{W}) \quad (1-25)$$

where  $\sigma = 5.670 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4$  or  $0.1714 \times 10^{-8} \text{ Btu/h} \cdot \text{ft}^2 \cdot \text{R}^4$  is the *Stefan–Boltzmann constant*. The idealized surface that emits radiation at this maximum rate is called a **blackbody**, and the radiation emitted by a blackbody is called **blackbody radiation** (Fig. 1–38). The radiation emitted by all real surfaces is less than the radiation emitted by a blackbody at the same temperature, and is expressed as

$$\dot{Q}_{\text{emit}} = \epsilon \sigma A_s T_s^4 \quad (\text{W}) \quad (1-26)$$

where  $\epsilon$  is the **emissivity** of the surface. The property emissivity, whose value is in the range  $0 \leq \epsilon \leq 1$ , is a measure of how closely a surface approximates a blackbody for which  $\epsilon = 1$ . The emissivities of some surfaces are given in Table 1–6.

Another important radiation property of a surface is its **absorptivity**  $\alpha$ , which is the fraction of the radiation energy incident on a surface that is absorbed by the surface. Like emissivity, its value is in the range  $0 \leq \alpha \leq 1$ . A blackbody absorbs the entire radiation incident on it. That is, a blackbody is a perfect absorber ( $\alpha = 1$ ) as it is a perfect emitter.

In general, both  $\epsilon$  and  $\alpha$  of a surface depend on the temperature and the wavelength of the radiation. **Kirchhoff's law** of radiation states that the emissivity and the absorptivity of a surface at a given temperature and wavelength are equal. In many practical applications, the surface temperature and the temperature of the source of incident radiation are of the same order of magnitude, and the average absorptivity of a surface is taken to be equal to its average emissivity. The rate at which a surface absorbs radiation is determined from (Fig. 1–39)

$$\dot{Q}_{\text{absorbed}} = \alpha \dot{Q}_{\text{incident}} \quad (\text{W}) \quad (1-27)$$

where  $\dot{Q}_{\text{incident}}$  is the rate at which radiation is incident on the surface and  $\alpha$  is the absorptivity of the surface. For opaque (nontransparent) surfaces, the portion of incident radiation not absorbed by the surface is reflected back.

The difference between the rates of radiation emitted by the surface and the radiation absorbed is the *net radiation heat transfer*. If the rate of radiation absorption is greater than the rate of radiation emission, the surface is said to be *gaining* energy by radiation. Otherwise, the surface is said to be *losing* energy by radiation. In general, the determination of the net rate of heat transfer by radiation between two surfaces is a complicated matter since it depends on the properties of the surfaces, their orientation relative to each other, and the interaction of the medium between the surfaces with radiation.

**FIGURE 1–39**

The absorption of radiation incident on an opaque surface of absorptivity  $\alpha$ .

When a surface of emissivity  $\varepsilon$  and surface area  $A_s$  at a *thermodynamic temperature*  $T_s$  is completely enclosed by a much larger (or black) surface at thermodynamic temperature  $T_{\text{surr}}$  separated by a gas (such as air) that does not intervene with radiation, the net rate of radiation heat transfer between these two surfaces is given by (Fig. 1–40)

$$\dot{Q}_{\text{rad}} = \varepsilon\sigma A_s (T_s^4 - T_{\text{surr}}^4) \quad (\text{W}) \quad (1-28)$$

In this special case, the emissivity and the surface area of the surrounding surface do not have any effect on the net radiation heat transfer.

Radiation heat transfer to or from a surface surrounded by a gas such as air occurs *parallel* to conduction (or convection, if there is bulk gas motion) between the surface and the gas. Thus the total heat transfer is determined by *adding* the contributions of both heat transfer mechanisms. For simplicity and convenience, this is often done by defining a **combined heat transfer coefficient**  $h_{\text{combined}}$  that includes the effects of both convection and radiation. Then the *total* heat transfer rate to or from a surface by convection and radiation is expressed as

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = h_{\text{conv}} A_s (T_s - T_{\text{surr}}) + \varepsilon\sigma A_s (T_s^4 - T_{\text{surr}}^4)$$

$$\dot{Q}_{\text{total}} = h_{\text{combined}} A_s (T_s - T_{\infty}) \quad (\text{W}) \quad (1-29)$$

$$h_{\text{combined}} = h_{\text{conv}} + h_{\text{rad}} = h_{\text{conv}} + \varepsilon\sigma (T_s + T_{\text{surr}})(T_s^2 + T_{\text{surr}}^2)$$

Note that the combined heat transfer coefficient is essentially a convection heat transfer coefficient modified to include the effects of radiation.

Radiation is usually significant relative to conduction or natural convection, but negligible relative to forced convection. Thus radiation in forced convection applications is usually disregarded, especially when the surfaces involved have low emissivities and low to moderate temperatures.

### EXAMPLE 1–9 Radiation Effect on Thermal Comfort

It is a common experience to feel “chilly” in winter and “warm” in summer in our homes even when the thermostat setting is kept the same. This is due to the so called “radiation effect” resulting from radiation heat exchange between our bodies and the surrounding surfaces of the walls and the ceiling.

Consider a person standing in a room maintained at 22°C at all times. The inner surfaces of the walls, floors, and the ceiling of the house are observed to be at an average temperature of 10°C in winter and 25°C in summer. Determine the rate of radiation heat transfer between this person and the surrounding surfaces if the exposed surface area and the average outer surface temperature of the person are 1.4 m<sup>2</sup> and 30°C, respectively (Fig. 1–41).

**SOLUTION** The rates of radiation heat transfer between a person and the surrounding surfaces at specified temperatures are to be determined in summer and winter.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer by convection is not considered. 3 The person is completely surrounded by the interior surfaces of the room. 4 The surrounding surfaces are at a uniform temperature.

**Properties** The emissivity of a person is  $\varepsilon = 0.95$  (Table 1–6).

FIGURE 1–40

Radiation heat transfer between a surface and the surfaces surrounding it.

FIGURE 1–41

Schematic for Example 1–9.

**Analysis** The net rates of radiation heat transfer from the body to the surrounding walls, ceiling, and floor in winter and summer are

$$\begin{aligned}\dot{Q}_{\text{rad, winter}} &= \varepsilon\sigma A_s (T_s^4 - T_{\text{surr, winter}}^4) \\ &= (0.95)(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4)(1.4 \text{ m}^2) \\ &\quad \times [(30 + 273)^4 - (10 + 273)^4] \text{ K}^4 \\ &= 152 \text{ W}\end{aligned}$$

and

$$\begin{aligned}\dot{Q}_{\text{rad, summer}} &= \varepsilon\sigma A_s (T_s^4 - T_{\text{surr, summer}}^4) \\ &= (0.95)(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4)(1.4 \text{ m}^2) \\ &\quad \times [(30 + 273)^4 - (25 + 273)^4] \text{ K}^4 \\ &= 40.9 \text{ W}\end{aligned}$$

**Discussion** Note that we must use *thermodynamic (i.e., absolute) temperatures* in radiation calculations. Also note that the rate of heat loss from the person by radiation is almost four times as large in winter than it is in summer, which explains the “chill” we feel in winter even if the thermostat setting is kept the same.

## 1–9 • SIMULTANEOUS HEAT TRANSFER MECHANISMS

**FIGURE 1–42**

Although there are three mechanisms of heat transfer, a medium may involve only two of them simultaneously.

We mentioned that there are three mechanisms of heat transfer, but not all three can exist simultaneously in a medium. For example, heat transfer is only by conduction in *opaque solids*, but by conduction and radiation in *semitransparent solids*. Thus, a solid may involve conduction and radiation but not convection. However, a solid may involve heat transfer by convection and/or radiation on its surfaces exposed to a fluid or other surfaces. For example, the outer surfaces of a cold piece of rock will warm up in a warmer environment as a result of heat gain by convection (from the air) and radiation (from the sun or the warmer surrounding surfaces). But the inner parts of the rock will warm up as this heat is transferred to the inner region of the rock by conduction.

Heat transfer is by conduction and possibly by radiation in a *still fluid* (no bulk fluid motion) and by convection and radiation in a *flowing fluid*. In the absence of radiation, heat transfer through a fluid is either by conduction or convection, depending on the presence of any bulk fluid motion. Convection can be viewed as combined conduction and fluid motion, and conduction in a fluid can be viewed as a special case of convection in the absence of any fluid motion (Fig. 1–42).

Thus, when we deal with heat transfer through a *fluid*, we have either *conduction* or *convection*, but not both. Also, gases are practically transparent to radiation, except that some gases are known to absorb radiation strongly at certain wavelengths. Ozone, for example, strongly absorbs ultraviolet radiation. But in most cases, a gas between two solid surfaces does not interfere with radiation and acts effectively as a vacuum. Liquids, on the other hand, are usually strong absorbers of radiation.

Finally, heat transfer through a *vacuum* is by radiation only since conduction or convection requires the presence of a material medium.

**EXAMPLE 1–10 Heat Loss from a Person**

Consider a person standing in a breezy room at 20°C. Determine the total rate of heat transfer from this person if the exposed surface area and the average outer surface temperature of the person are 1.6 m<sup>2</sup> and 29°C, respectively, and the convection heat transfer coefficient is 6 W/m<sup>2</sup>·K (Fig. 1–43).

**SOLUTION** The total rate of heat transfer from a person by both convection and radiation to the surrounding air and surfaces at specified temperatures is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The person is completely surrounded by the interior surfaces of the room. 3 The surrounding surfaces are at the same temperature as the air in the room. 4 Heat conduction to the floor through the feet is negligible.

**Properties** The emissivity of a person is  $\varepsilon = 0.95$  (Table 1–6).

**Analysis** The heat transfer between the person and the air in the room is by convection (instead of conduction) since it is conceivable that the air in the vicinity of the skin or clothing warms up and rises as a result of heat transfer from the body, initiating natural convection currents. It appears that the experimentally determined value for the rate of convection heat transfer in this case is 6 W per unit surface area (m<sup>2</sup>) per unit temperature difference (in K or °C) between the person and the air away from the person. Thus, the rate of convection heat transfer from the person to the air in the room is

$$\begin{aligned}\dot{Q}_{\text{conv}} &= hA_s(T_s - T_\infty) \\ &= (6 \text{ W/m}^2\cdot\text{K})(1.6 \text{ m}^2)(29 - 20)^\circ\text{C} \\ &= 86.4 \text{ W}\end{aligned}$$

The person also loses heat by radiation to the surrounding wall surfaces. We take the temperature of the surfaces of the walls, ceiling, and floor to be equal to the air temperature in this case for simplicity, but we recognize that this does not need to be the case. These surfaces may be at a higher or lower temperature than the average temperature of the room air, depending on the outdoor conditions and the structure of the walls. Considering that air does not intervene with radiation and the person is completely enclosed by the surrounding surfaces, the net rate of radiation heat transfer from the person to the surrounding walls, ceiling, and floor is

$$\begin{aligned}\dot{Q}_{\text{rad}} &= \varepsilon\sigma A_s(T_s^4 - T_{\text{surr}}^4) \\ &= (0.95)(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4)(1.6 \text{ m}^2) \\ &\quad \times [(29 + 273)^4 - (20 + 273)^4] \text{ K}^4 \\ &= 81.7 \text{ W}\end{aligned}$$

Note that we must use *thermodynamic* temperatures in radiation calculations. Also note that we used the emissivity value for the skin and clothing at room temperature since the emissivity is not expected to change significantly at a slightly higher temperature.

Then the rate of total heat transfer from the body is determined by adding these two quantities:

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = (86.4 + 81.7) \text{ W} \cong 168 \text{ W}$$

**FIGURE 1–43**

Heat transfer from the person described in Example 1–10.

**Discussion** The heat transfer would be much higher if the person were not dressed since the exposed surface temperature would be higher. Thus, an important function of the clothes is to serve as a barrier against heat transfer.

In these calculations, heat transfer through the feet to the floor by conduction, which is usually very small, is neglected. Heat transfer from the skin by perspiration, which is the dominant mode of heat transfer in hot environments, is not considered here.

Also, the units  $\text{W}/\text{m}^2 \cdot ^\circ\text{C}$  and  $\text{W}/\text{m}^2 \cdot \text{K}$  for heat transfer coefficient are equivalent, and can be interchanged.

**FIGURE 1–44**

Schematic for Example 1–11.

### EXAMPLE 1–11 Heat Transfer between Two Isothermal Plates

Consider steady heat transfer between two large parallel plates at constant temperatures of  $T_1 = 300 \text{ K}$  and  $T_2 = 200 \text{ K}$  that are  $L = 1 \text{ cm}$  apart, as shown in Fig. 1–44. Assuming the surfaces to be black (emissivity  $\varepsilon = 1$ ), determine the rate of heat transfer between the plates per unit surface area assuming the gap between the plates is (a) filled with atmospheric air, (b) evacuated, (c) filled with urethane insulation, and (d) filled with superinsulation that has an apparent thermal conductivity of  $0.00002 \text{ W}/\text{m}\cdot\text{K}$ .

**SOLUTION** The total rate of heat transfer between two large parallel plates at specified temperatures is to be determined for four different cases.

**Assumptions** 1 Steady operating conditions exist. 2 There are no natural convection currents in the air between the plates. 3 The surfaces are black and thus  $\varepsilon = 1$ .

**Properties** The thermal conductivity at the average temperature of  $250 \text{ K}$  is  $k = 0.0219 \text{ W}/\text{m}\cdot\text{K}$  for air (Table A–15),  $0.026 \text{ W}/\text{m}\cdot\text{K}$  for urethane insulation (Table A–6), and  $0.00002 \text{ W}/\text{m}\cdot\text{K}$  for the superinsulation.

**Analysis** (a) The rates of conduction and radiation heat transfer between the plates through the air layer are

$$\dot{Q}_{\text{cond}} = kA \frac{T_1 - T_2}{L} = (0.0219 \text{ W}/\text{m}\cdot\text{K})(1 \text{ m}^2) \frac{(300 - 200)\text{K}}{0.01 \text{ m}} = 219 \text{ W}$$

and

$$\begin{aligned}\dot{Q}_{\text{rad}} &= \varepsilon\sigma A(T_1^4 - T_2^4) \\ &= (1)(5.67 \times 10^{-8} \text{ W}/\text{m}^2 \cdot \text{K}^4)(1 \text{ m}^2)[(300 \text{ K})^4 - (200 \text{ K})^4] = 369 \text{ W}\end{aligned}$$

Therefore,

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{cond}} + \dot{Q}_{\text{rad}} = 219 + 369 = 588 \text{ W}$$

The heat transfer rate in reality will be higher because of the natural convection currents that are likely to occur in the air space between the plates.

(b) When the air space between the plates is evacuated, there will be no conduction or convection, and the only heat transfer between the plates will be by radiation. Therefore,

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{rad}} = 369 \text{ W}$$

(c) An opaque solid material placed between two plates blocks direct radiation heat transfer between the plates. Also, the thermal conductivity of an insulating material accounts for the radiation heat transfer that may be occurring

FIGURE 1-45

Different ways of reducing heat transfer between two isothermal plates, and their effectiveness.

through the voids in the insulating material. The rate of heat transfer through the urethane insulation is

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{cond}} = kA \frac{T_1 - T_2}{L} = (0.026 \text{ W/m}\cdot\text{K})(1 \text{ m}^2) \frac{(300 - 200)\text{K}}{0.01 \text{ m}} = 260 \text{ W}$$

Note that heat transfer through the urethane material is less than the heat transfer through the air determined in (a), although the thermal conductivity of the insulation is higher than that of air. This is because the insulation blocks the radiation whereas air transmits it.

(d) The layers of the superinsulation prevent any direct radiation heat transfer between the plates. However, radiation heat transfer between the sheets of superinsulation does occur, and the apparent thermal conductivity of the superinsulation accounts for this effect. Therefore,

$$\dot{Q}_{\text{total}} = kA \frac{T_1 - T_2}{L} = (0.00002 \text{ W/m}\cdot\text{K})(1 \text{ m}^2) \frac{(300 - 200)\text{K}}{0.01 \text{ m}} = 0.2 \text{ W}$$

which is  $\frac{1}{1845}$  of the heat transfer through the vacuum. The results of this example are summarized in Fig. 1-45 to put them into perspective.

**Discussion** This example demonstrates the effectiveness of superinsulations and explains why they are the insulation of choice in critical applications despite their high cost.

### EXAMPLE 1-12 Heat Transfer in Conventional and Microwave Ovens

The fast and efficient cooking of microwave ovens made them one of the essential appliances in modern kitchens (Fig. 1-46). Discuss the heat transfer mechanisms associated with the cooking of a chicken in microwave and conventional ovens, and explain why cooking in a microwave oven is more efficient.

**SOLUTION** Food is cooked in a microwave oven by absorbing the electromagnetic radiation energy generated by the microwave tube, called the magnetron.

FIGURE 1-46

A chicken being cooked in a microwave oven (Example 1-12).

The radiation emitted by the magnetron is not thermal radiation, since its emission is not due to the temperature of the magnetron; rather, it is due to the conversion of electrical energy into electromagnetic radiation at a specified wavelength. The wavelength of the microwave radiation is such that it is *reflected* by metal surfaces; *transmitted* by the cookware made of glass, ceramic, or plastic; and *absorbed* and converted to internal energy by food (especially the water, sugar, and fat) molecules.

In a microwave oven, the *radiation* that strikes the chicken is absorbed by the skin of the chicken and the outer parts. As a result, the temperature of the chicken at and near the skin rises. Heat is then *conducted* toward the inner parts of the chicken from its outer parts. Of course, some of the heat absorbed by the outer surface of the chicken is lost to the air in the oven by *convection*.

In a conventional oven, the air in the oven is first heated to the desired temperature by the electric or gas heating element. This preheating may take several minutes. The heat is then transferred from the air to the skin of the chicken by *natural convection* in older ovens or by *forced convection* in the newer convection ovens that utilize a fan. The air motion in convection ovens increases the convection heat transfer coefficient and thus decreases the cooking time. Heat is then *conducted* toward the inner parts of the chicken from its outer parts as in microwave ovens.

Microwave ovens replace the slow convection heat transfer process in conventional ovens by the instantaneous radiation heat transfer. As a result, microwave ovens transfer energy to the food at full capacity the moment they are turned on, and thus they cook faster while consuming less energy.

**FIGURE 1–47**

Schematic for Example 1–13.

### EXAMPLE 1–13 Heating of a Plate by Solar Energy

A thin metal plate is insulated on the back and exposed to solar radiation at the front surface (Fig. 1–47). The exposed surface of the plate has an absorptivity of 0.6 for solar radiation. If solar radiation is incident on the plate at a rate of  $700 \text{ W/m}^2$  and the surrounding air temperature is  $25^\circ\text{C}$ , determine the surface temperature of the plate when the heat loss by convection and radiation equals the solar energy absorbed by the plate. Assume the combined convection and radiation heat transfer coefficient to be  $50 \text{ W/m}^2\cdot\text{K}$ .

**SOLUTION** The back side of the thin metal plate is insulated and the front side is exposed to solar radiation. The surface temperature of the plate is to be determined when it stabilizes.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer through the insulated side of the plate is negligible. 3 The heat transfer coefficient remains constant.

**Properties** The solar absorptivity of the plate is given to be  $\alpha = 0.6$ .

**Analysis** The absorptivity of the plate is 0.6, and thus 60 percent of the solar radiation incident on the plate is absorbed continuously. As a result, the temperature of the plate rises, and the temperature difference between the plate and the surroundings increases. This increasing temperature difference causes the rate of heat loss from the plate to the surroundings to increase. At some

point, the rate of heat loss from the plate equals the rate of solar energy absorbed, and the temperature of the plate no longer changes. The temperature of the plate when steady operation is established is determined from

$$\dot{E}_{\text{gained}} = \dot{E}_{\text{lost}} \quad \text{or} \quad \alpha A_s \dot{q}_{\text{incident, solar}} = h_{\text{combined}} A_s (T_s - T_\infty)$$

Solving for  $T_s$  and substituting, the plate surface temperature is determined to be

$$T_s = T_\infty + \alpha \frac{\dot{q}_{\text{incident, solar}}}{h_{\text{combined}}} = 25^\circ\text{C} + \frac{0.6 \times (700 \text{ W/m}^2)}{50 \text{ W/m}^2 \cdot \text{K}} = 33.4^\circ\text{C}$$

**Discussion** Note that the heat losses prevent the plate temperature from rising above 33.4°C. Also, the combined heat transfer coefficient accounts for the effects of both convection and radiation, and thus it is very convenient to use in heat transfer calculations when its value is known with reasonable accuracy.

## 1–10 • PREVENTION THROUGH DESIGN\*

The emphasis of safety is not foreign in the fields of engineering. It is without any surprise that the first of the fundamental canons of ethics for engineers is to “hold paramount the safety, health, and welfare of the public” when fulfilling their professional duties (NSPE Publication 1102, 2007). In 2007, the National Institute for Occupational Safety and Health (NIOSH) launched the National Prevention through Design (PtD) initiative, with the mission to prevent or reduce work-related injuries, illnesses, and fatalities by including prevention considerations in all circumstances that impact individuals in the work places (NIOSH Publication 2011–121, 2010). As such, the concept of PtD involves applying the means of reducing risks and preventing hazards in the design of equipment, tools, processes, and work facilities. The idea of having a section on PtD throughout the different chapters in the text is not only to simply provide discussions of interesting real world applications, but also to introduce the concepts of PtD to the minds of tomorrow’s engineers whereby they may influence a change in culture toward more emphasis on safety designs.

The National PtD Initiative is largely being discussed in the context of preventing work-related hazards to individuals in working environments. Nevertheless, the concepts of PtD can also be rationally applied to preventing failures and damages of devices, products, and systems. Since such failures and damages are often led to negative impacts on the environment, profitability, and ultimately the society at large. Within the context of heat and mass transfer, the PtD concepts can be presented along with the physical mechanisms involved and practical applications. Issues such as prevention of thermal burn, fire hazard, and thermal failure in systems are topics that can relate the concepts of PtD with the basic science of heat and mass transfer. The process of solving heat and mass transfer problems, along with the

\*The section is contributed by Professor Clement C. Tang, Mechanical Engineering Department, University of North Dakota, Grand Forks, ND.

**FIGURE 1-48**

Process of solving problems with application of PtD concepts

application of PtD concepts, involves incorporating prescribed PtD criteria, be it the prevention of burn injury, fire hazard, or system failure, to the solutions (Fig. 1-48). To successfully arrive at a solution that satisfies prescribed PtD criteria requires the understanding of how the physical mechanisms of heat and mass transfer interrelate with the concepts of PtD.

Thermal burn occurs when skin tissues are exposed to temperatures that are higher than its physiological temperature. Under such occurrence, the protein and cellular structures of skin tissues are altered, as the higher temperatures cause thermal shocks and disrupt the skin cells. The degree of injury as a result of thermal burn is influenced by the temperature to which the skin is exposed and the duration of exposure. The skin reaction to thermal burn is dependent upon the heat transfer rate from the hot medium to the skin. When exposed to temperatures above approximately 43°C, the human skin can begin to feel discomfort and pain; and damage can occur if the exposure is sufficiently long. Exposure to temperature about 48°C can cause human skin to receive a first degree burn injury; and temperature above 70°C can cause instantaneous damage to human skin (ASTM Standard C1055-03, 2009).

Injury from thermal burn can result from all three modes of heat transfer: conduction, convection, and radiation. Thermal burn by conduction heat transfer occurs when the skin is in contact with a hot solid surface. The thermal properties, roughness, and temperature of the hot solid surface, along with the contact duration and the nature of the skin, all influence the degree of this thermal burn injury. Scalding of skin from hot fluid is a thermal burn caused by convection heat transfer to the skin. Scalding on skin tissue can occur through spilling of hot liquid or accidental immersion into hot liquid. Thermal burn injuries from convection heat transfer of hot gas are not only external but also can be internal, affecting the upper respiratory tract and even the lungs. Thermal burn by radiation can be caused from laser or other sources such as nuclear explosion. Although human skin can reflect much of the incident energy from radiation, exposure to high energy laser beams can cause thermal burn on skin. The severity of thermal burn from laser is influenced by the range of wavelength that allows the laser beam to penetrate into the skin tissue and the duration of exposure.

In the prevention of fire hazard, the understanding of flash point is important. Flash point is the lowest temperature at which a liquid can vaporize and form a mixture with air to become ignitable. When a liquid reaches its flash point, a source of ignition (e.g., open flame, spark, static electricity, and hot object) will cause the liquid to ignite. Therefore designs for fire hazard prevention must be in place when storing, handling, or transporting a liquid above its flash point, such that it is not exposed to an ignition source. The lower the flash point of a liquid, the more susceptible it is to a fire hazard. Flash point is also used for characterizing fire hazard of liquids into categories such as combustible and flammable liquids. The National Fire Protection Association (NFPA) has classified a liquid with a flash point of 37.8°C (100°F) or higher as a combustible liquid. A liquid with a flash point below 37.8°C is classified as flammable liquid. Another concept important to fire hazard prevention is the autoignition temperature (AIT), which is the minimum temperature at which a substance will spontaneously ignite without ignition source. A substance is auto ignited when it is heated above a temperature at which the rate of heat release from the exothermic oxidation reaction become significantly

greater than the rate of heat lost to the surroundings. Factors influencing the autoignition temperature include atmospheric pressure, humidity, and oxygen concentration.

The science of heat and mass transfer can be coupled with the concepts of PtD to mitigate the risks of thermal failure in systems. Thermal stress can compromise the integrity of parts and components in a system. Extreme temperature can alter the physical properties of a material, which can cause a component to lose its functionality. Cold temperature on the morning of January 28, 1986 affected the elasticity of the O-ring on a solid rocket booster of the space shuttle Challenger. The loss of the O-ring's elasticity and ability to seal allowed hot combustion gas to leak through a solid rocket booster, which led to the tragic disaster.

### PtD EXAMPLE 1-14

### Fire Hazard Prevention of Oil Leakage on Hot Engine Surface

Oil leakage and spillage on hot engine surface can lead to fire hazards. Some engine oils have an autoignition temperature of approximately above 250°C. When oil leakage comes in contact with a hot engine surface that has a higher temperature than its autoignition temperature, the oil can ignite spontaneously. Consider the outer surface of an engine situated in a place where there is a possibility of being in contact with oil leakage. The engine surface has an emissivity of 0.3, and when it is in operation, its inner surface is subjected to 5 kW/m<sup>2</sup> of heat flux. The engine is in an environment where the ambient air and surrounding temperature is 40°C, while the convection heat transfer coefficient is 15 W/m<sup>2</sup>·K. To prevent a fire hazard in the event of oil leakage being in contact with the engine surface, the temperature of the engine surface should be kept below 200°C. Determine whether oil leakage drops on the engine surface are at a risk of autoignition. If there is a risk of autoignition, discuss a possible prevention measure that can be implemented.

**SOLUTION** In this example, the concepts of PtD are applied with the basic understanding of simultaneous heat transfer mechanisms via convection and radiation. The inner surface of an engine is subject to a heat flux of 5 kW/m<sup>2</sup>. The engine surface temperature is to be determined whether it is below 200°C, to prevent spontaneous ignition in the event of oil leakage drops on the engine surface.

**Assumptions** 1 Steady operating conditions exist. 2 The surrounding surfaces are at the same temperature as the ambient air. 3 Heat conduction through the engine housing is one-dimensional. 4 The engine inner surface is subjected to uniform heat flux.

**Properties** Emissivity of the engine surface is given as  $\varepsilon = 0.3$ .

**Analysis** When in operation, the inner surface of the engine is subjected to a uniform heat flux, which is equal to the sum of heat fluxes transferred by convection and radiation on the outer surface. Therefore,

$$\dot{q}_0 = h(T_o - T_\infty) + \varepsilon\sigma(T_o^4 - T_{\text{surr}}^4)$$

$$5000 \text{ W/m}^2 = (15 \text{ W/m}^2 \cdot \text{K})[T_o - (40 + 273)]\text{K} \\ + (0.3)(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)[T_o^4 - (40 + 273)^4]\text{K}^4$$

**FIGURE 1-49**  
Schematic for Example 1-14

The engine outer surface temperature ( $T_0$ ) can be solved implicitly using the Engineering Equation Solver (EES) software that accompanies this text with the following lines:

```

h=15 [W/m^2-K]
q_dot_0=5000 [W/m^2]
T_surr=313 [K]
epsilon=0.3
sigma=5.67e-8 [W/m^2-K^4]
q_dot_0=h*(T_o-T_surr)+epsilon*sigma*(T_o^4-T_surr^4)

```

The engine outer surface temperature is found to be  $T_o = 552 \text{ K} = 279^\circ\text{C}$

**Discussion** The solution reveals that the engine outer surface temperature is greater than  $200^\circ\text{C}$ , the temperature required to prevent the risk of autoignition in the event of oil leakage drops on the engine outer surface. To mitigate the risk of fire hazards, the outer surface of the engine should be insulated. In practice, the engine surface temperature is not uniform; instead, high local surface temperatures result in hot spots on the engine surface. Engine housings generally come in irregular shapes, thus making the prediction of hot spots on the engine surface difficult. However, using handheld infrared thermometers, engine operators can quickly identify the approximate areas that are prone to hot spots and take proper prevention measures.

**FIGURE 1–50**

A step-by-step approach can greatly simplify problem solving.

## 1–11 ■ PROBLEM-SOLVING TECHNIQUE

The first step in learning any science is to grasp the fundamentals and to gain a sound knowledge of it. The next step is to master the fundamentals by testing this knowledge. This is done by solving significant real-world problems. Solving such problems, especially complicated ones, requires a systematic approach. By using a step-by-step approach, an engineer can reduce the solution of a complicated problem into the solution of a series of simple problems (Fig. 1–50). When you are solving a problem, we recommend that you use the following steps zealously as applicable. This will help you avoid some of the common pitfalls associated with problem solving.

### Step 1: Problem Statement

In your own words, briefly state the problem, the key information given, and the quantities to be found. This is to make sure that you understand the problem and the objectives before you attempt to solve the problem.

### Step 2: Schematic

Draw a realistic sketch of the physical system involved, and list the relevant information on the figure. The sketch does not have to be something elaborate, but it should resemble the actual system and show the key features. Indicate any energy and mass interactions with the surroundings. Listing the given information on the sketch helps one to see the entire problem at once.

### Step 3: Assumptions and Approximations

State any appropriate assumptions and approximations made to simplify the problem to make it possible to obtain a solution. Justify the questionable

assumptions. Assume reasonable values for missing quantities that are necessary. For example, in the absence of specific data for atmospheric pressure, it can be taken to be 1 atm. However, it should be noted in the analysis that the atmospheric pressure decreases with increasing elevation. For example, it drops to 0.83 atm in Denver (elevation 1610 m) (Fig. 1–51).

### Step 4: Physical Laws

Apply all the relevant basic physical laws and principles (such as the conservation of energy), and reduce them to their simplest form by utilizing the assumptions made. However, the region to which a physical law is applied must be clearly identified first.

### Step 5: Properties

Determine the unknown properties necessary to solve the problem from property relations or tables. List the properties separately, and indicate their source, if applicable.

### Step 6: Calculations

Substitute the known quantities into the simplified relations and perform the calculations to determine the unknowns. Pay particular attention to the units and unit cancellations, and remember that a dimensional quantity without a unit is meaningless. Also, don't give a false implication of high precision by copying all the digits from the calculator—round the results to an appropriate number of significant digits (see p. 42).

### Step 7: Reasoning, Verification, and Discussion

Check to make sure that the results obtained are reasonable and intuitive, and verify the validity of the questionable assumptions. Repeat the calculations that resulted in unreasonable values. For example, insulating a water heater that uses \$80 worth of natural gas a year cannot result in savings of \$200 a year (Fig. 1–52).

Also, point out the significance of the results, and discuss their implications. State the conclusions that can be drawn from the results, and any recommendations that can be made from them. Emphasize the limitations under which the results are applicable, and caution against any possible misunderstandings and using the results in situations where the underlying assumptions do not apply. For example, if you determined that wrapping a water heater with a \$20 insulation jacket will reduce the energy cost by \$30 a year, indicate that the insulation will pay for itself from the energy it saves in less than a year. However, also indicate that the analysis does not consider labor costs, and that this will be the case if you install the insulation yourself.

Keep in mind that the solutions you present to your instructors, and any engineering analysis presented to others, are a form of communication. Therefore neatness, organization, completeness, and visual appearance are of utmost importance for maximum effectiveness (Fig. 1–53). Besides, neatness also serves as a great checking tool since it is very easy to spot errors and inconsistencies in neat work. Carelessness and skipping steps to save time often end up costing more time and unnecessary anxiety.

The approach described here is used in the solved example problems without explicitly stating each step, as well as in the Solutions Manual of this text. For some problems, some of the steps may not be applicable or necessary.

| <b>IMPOSSIBLE!</b>                   |

FIGURE 1–52

The results obtained from an engineering analysis must be checked for reasonableness.

FIGURE 1–53

Neatness and organization are highly valued by employers.

However, we cannot overemphasize the importance of a logical and orderly approach to problem solving. Most difficulties encountered while solving a problem are not due to a lack of knowledge; rather, they are due to a lack of organization. You are strongly encouraged to follow these steps in problem solving until you develop your own approach that works best for you.

## Engineering Software Packages

You may be wondering why we are about to undertake an in-depth study of the fundamentals of another engineering science. After all, almost all such problems we are likely to encounter in practice can be solved using one of several sophisticated software packages readily available in the market today. These software packages not only give the desired numerical results, but also supply the outputs in colorful graphical form for impressive presentations. It is unthinkable to practice engineering today without using some of these packages. This tremendous computing power available to us at the touch of a button is both a blessing and a curse. It certainly enables engineers to solve problems easily and quickly, but it also opens the door for abuses and misinformation. In the hands of poorly educated people, these software packages are as dangerous as sophisticated powerful weapons in the hands of poorly trained soldiers.

Thinking that a person who can use the engineering software packages without proper training on fundamentals can practice engineering is like thinking that a person who can use a wrench can work as a car mechanic. If it were true that the engineering students do not need all these fundamental courses they are taking because practically everything can be done by computers quickly and easily, then it would also be true that the employers would no longer need high-salaried engineers since any person who knows how to use a word-processing program can also learn how to use those software packages. However, the statistics show that the need for engineers is on the rise, not on the decline, despite the availability of these powerful packages.

We should always remember that all the computing power and the engineering software packages available today are just tools, and tools have meaning only in the hands of masters. Having the best word-processing program does not make a person a good writer, but it certainly makes the job of a good writer much easier and makes the writer more productive (Fig. 1–54). Hand calculators did not eliminate the need to teach our children how to add or subtract, and the sophisticated medical software packages did not take the place of medical school training. Neither will engineering software packages replace the traditional engineering education. They will simply cause a shift in emphasis in the courses from mathematics to physics. That is, more time will be spent in the classroom discussing the physical aspects of the problems in greater detail, and less time on the mechanics of solution procedures.

All these marvelous and powerful tools available today put an extra burden on today's engineers. They must still have a thorough understanding of the fundamentals, develop a "feel" of the physical phenomena, be able to put the data into proper perspective, and make sound engineering judgments, just like their predecessors. However, they must do it much better, and much faster, using more realistic models because of the powerful tools available

**FIGURE 1–54**

An excellent word-processing program does not make a person a good writer; it simply makes a good writer a better and more efficient writer.

© Vol. 80/PhotoDisc/Getty Images RF

today. The engineers in the past had to rely on hand calculations, slide rules, and later hand calculators and computers. Today they rely on software packages. The easy access to such power and the possibility of a simple misunderstanding or misinterpretation causing great damage make it more important today than ever to have solid training in the fundamentals of engineering. In this text we make an extra effort to put the emphasis on developing an intuitive and physical understanding of natural phenomena instead of on the mathematical details of solution procedures.

## Engineering Equation Solver (EES)

EES is a program that solves systems of linear or nonlinear algebraic or differential equations numerically. It has a large library of built-in thermophysical property functions as well as mathematical functions, and allows the user to supply additional property data. Unlike some software packages, EES does not solve engineering problems; it only solves the equations supplied by the user. Therefore, the user must understand the problem and formulate it by applying any relevant physical laws and relations. EES saves the user considerable time and effort by simply solving the resulting mathematical equations. This makes it possible to attempt significant engineering problems not suitable for hand calculations, and to conduct parametric studies quickly and conveniently. EES is a very powerful yet intuitive program that is very easy to use, as shown in Example 1–15. The use and capabilities of EES are explained in Appendix 3 on the Online Learning Center.

### EXAMPLE 1–15 Solving a System of Equations with EES

The difference of two numbers is 4, and the sum of the squares of these two numbers is equal to the sum of the numbers plus 20. Determine these two numbers.

**SOLUTION** Relations are given for the difference and the sum of the squares of two numbers. They are to be determined.

**Analysis** We start the EES program by double-clicking on its icon, open a new file, and type the following on the blank screen that appears:

$$\begin{aligned}x - y &= 4 \\x^2 + y^2 &= x + y + 20\end{aligned}$$

which is an exact mathematical expression of the problem statement with  $x$  and  $y$  denoting the unknown numbers. The solution to this system of two nonlinear equations with two unknowns is obtained by a single click on the “calculator” symbol on the taskbar. It gives (Fig. 1–55)

$$x = 5 \text{ and } y = 1$$

**Discussion** Note that all we did is formulate the problem as we would on paper; EES took care of all the mathematical details of solution. Also note that equations can be linear or nonlinear, and they can be entered in any order with unknowns on either side. Friendly equation solvers such as EES allow the user to concentrate on the physics of the problem without worrying about the mathematical complexities associated with the solution of the resulting system of equations.

**FIGURE 1–55**  
EES screen images for Example 1–15.

## A Remark on Significant Digits

In engineering calculations, the information given is not known to more than a certain number of significant digits, usually three digits. Consequently, the results obtained cannot possibly be accurate to more significant digits. Reporting results in more significant digits implies greater accuracy than exists, and it should be avoided.

For example, consider a 3.75-L container filled with gasoline whose density is 0.845 kg/L, and try to determine its mass. Probably the first thought that comes to your mind is to multiply the volume and density to obtain 3.16875 kg for the mass, which falsely implies that the mass determined is accurate to six significant digits. In reality, however, the mass cannot be more accurate than three significant digits since both the volume and the density are accurate to three significant digits only. Therefore, the result should be rounded to three significant digits, and the mass should be reported to be 3.17 kg instead of what appears in the screen of the calculator. The result 3.16875 kg would be correct only if the volume and density were given to be 3.75000 L and 0.845000 kg/L, respectively. The value 3.75 L implies that we are fairly confident that the volume is accurate within  $\pm 0.01$  L, and it cannot be 3.74 or 3.76 L. However, the volume can be 3.746, 3.750, 3.753, etc., since they all round to 3.75 L (Fig. 1–56). It is more appropriate to retain all the digits during intermediate calculations, and to do the rounding in the final step since this is what a computer will normally do.

When solving problems, we will assume the given information to be accurate to at least three significant digits. Therefore, if the length of a pipe is given to be 40 m, we will assume it to be 40.0 m in order to justify using three significant digits in the final results. You should also keep in mind that all experimentally determined values are subject to measurement errors, and such errors are reflected in the results obtained. For example, if the density of a substance has an uncertainty of 2 percent, then the mass determined using this density value will also have an uncertainty of 2 percent.

You should also be aware that we sometimes knowingly introduce small errors in order to avoid the trouble of searching for more accurate data. For example, when dealing with liquid water, we just use the value of  $1000 \text{ kg/m}^3$  for density, which is the density value of pure water at  $0^\circ\text{C}$ . Using this value at  $75^\circ\text{C}$  will result in an error of 2.5 percent since the density at this temperature is  $975 \text{ kg/m}^3$ . The minerals and impurities in the water introduce additional error. This being the case, you should have no reservation in rounding the final results to a reasonable number of significant digits. Besides, having a few percent uncertainty in the results of engineering analysis is usually the norm, not the exception.

When writing intermediate results in a computation, it is advisable to keep several “extra” digits to avoid round-off errors; however, the final result should be written with the number of significant digits taken into consideration. You must also keep in mind that a certain number of significant digits of precision in the result does not necessarily imply the same number of digits of overall *accuracy*. Bias error in one of the readings may, for example, significantly reduce the overall accuracy of the result, perhaps even rendering the last significant digit meaningless, and reducing the overall number

|                       |   |
|-----------------------|---|
| <input type="radio"/> | <b>Given:</b> Volume: $V = 3.75 \text{ L}$                        |
| <input type="radio"/> | Density: $\rho = 0.845 \text{ kg/L}$<br>(3 significant digits)    |
|                       | Also, $3.75 \times 0.845 = 3.16875$                               |
|                       | <b>Find:</b> Mass: $m = \rho V = 3.16875 \text{ kg}$              |
| <input type="radio"/> | <b>Rounding to 3 significant digits:</b><br>$m = 3.17 \text{ kg}$ |
| <input type="radio"/> |   |
| <input type="radio"/> |   |
| <input type="radio"/> |   |

**FIGURE 1–56**

A result with more significant digits than that of given data falsely implies more accuracy.

of reliable digits by one. Experimentally determined values are subject to measurement errors, and such errors are reflected in the results obtained. For example, if the density of a substance has an uncertainty of 2 percent, then the mass determined using this density value will also have an uncertainty of 2 percent.

Finally, when the number of significant digits is unknown, the accepted engineering standard is three significant digits. Therefore, if the length of a pipe is given to be 40 m, we will assume it to be 40.0 m in order to justify using three significant digits in the final results.

### TOPIC OF SPECIAL INTEREST\*

#### *Thermal Comfort*

Unlike animals such as a fox or a bear that are born with fur, human beings come into this world with little protection against the harsh environmental conditions (Fig. 1–57). Therefore, we can claim that the search for thermal comfort dates back to the beginning of human history. It is believed that early human beings lived in caves that provided shelter as well as protection from extreme thermal conditions. Probably the first form of heating system used was *open fire*, followed by fire in dwellings through the use of a *chimney* to vent out the combustion gases. The concept of *central heating* dates back to the times of the Romans, who heated homes by utilizing double-floor construction techniques and passing the fire's fumes through the opening between the two floor layers. The Romans were also the first to use *transparent windows* made of mica or glass to keep the wind and rain out while letting the light in. Wood and coal were the primary energy sources for heating, and oil and candles were used for lighting. The ruins of south-facing houses indicate that the value of *solar heating* was recognized early in the history.

The term **air-conditioning** is usually used in a restricted sense to imply cooling, but in its broad sense it means *to condition* the air to the desired level by heating, cooling, humidifying, dehumidifying, cleaning, and deodorizing. The purpose of the air-conditioning system of a building is to provide *complete thermal comfort* for its occupants. Therefore, we need to understand the thermal aspects of the *human body* in order to design an effective air-conditioning system.

The building blocks of living organisms are *cells*, which resemble miniature factories performing various functions necessary for the survival of organisms. The human body contains about 100 trillion cells with an average

\*Multiply by 1.8 m<sup>2</sup> to obtain metabolic rates for an average man. Multiply by 0.3171 to convert to Btu/h·ft<sup>2</sup>.

diameter of 0.01 mm. In a typical cell, thousands of chemical reactions occur every second during which some molecules are broken down and energy is released and some new molecules are formed. The high level of chemical activity in all cells helps to maintain the human body temperature of 37.0°C (98.6°F) while performing the necessary bodily functions to sustain life. Combination of these processes is called the **metabolism**. In simple terms, metabolism refers to the burning of foods such as carbohydrates, fat, and protein. The metabolizable energy content of foods is usually expressed by nutritionists in terms of the capitalized Calorie. One Calorie is equivalent to 1 Cal = 1 kcal = 4.1868 kJ.

The rate of metabolism at the resting state is called the *basal metabolic rate*, which is the rate of metabolism required to keep a body performing the necessary bodily functions such as breathing and blood circulation at zero external activity level. The metabolic rate can also be interpreted as the energy consumption rate for a body. For an *average man* (30 years old, 70 kg, 1.73 m high, 1.8 m<sup>2</sup> surface area), the basal metabolic rate is 84 W. That is, the body converts chemical energy of the food (or of the body fat if the person had not eaten) into heat at a rate of 84 J/s, which is then dissipated to the surroundings. The metabolic rate increases with the *level of activity*, and it may exceed 10 times the basal metabolic rate when someone is doing strenuous exercise. That is, two people doing heavy exercising in a room may be supplying more energy to the room than a 1-kW resistance heater (Fig. 1–58). An average man generates heat at a rate of 108 W while reading, writing, typing, or listening to a lecture in a classroom in a seated position. The maximum metabolic rate of an average man is 1250 W at age 20 and 730 at age 70. The corresponding rates for women are about 30 percent lower. Maximum metabolic rates of trained athletes can exceed 2000 W.

Metabolic rates during various activities are given in Table 1–7 per unit body surface area. The **surface area** of a nude body was given by D. DuBois in 1916 as

$$A_s = 0.202m^{0.425} h^{0.725} \quad (\text{m}^2) \quad (1-30)$$

where *m* is the mass of the body in kg and *h* is the height in m. *Clothing* increases the surface area of a person by up to about 50 percent and may provide additional resistance to dissipation of heat. The metabolic rates given in the table are sufficiently accurate for most purposes, but there is considerable uncertainty at high activity levels. More accurate values can be determined by measuring the rate of respiratory *oxygen consumption*, which ranges from about 0.25 L/min for an average resting man to more than 2 L/min during extremely heavy work. The entire energy released during metabolism can be assumed to be released as *heat* (in sensible or latent forms) since the external mechanical work done by the muscles is very small. Besides, the work done during most activities such as walking or riding an exercise bicycle is eventually converted to heat through friction.

The comfort of the human body depends primarily on three environmental factors: the temperature, relative humidity, and air motion. The temperature of the environment is the single most important index of comfort. Extensive research is done on human subjects to determine the “**thermal comfort zone**” and to identify the conditions under which the body feels comfortable in an environment. It has been observed that most normally clothed people resting or doing light work feel comfortable in the *operative temperature* (roughly, the average temperature of air and surrounding surfaces) range of 23°C to 27°C or 73°F to 80°F (Fig. 1–59). For unclothed people, this range is 29°C to 31°C. Interestingly, the operative temperature is higher than the average temperature of many highly populated areas in the world, which tend to have an average yearly temperature in the range of 15°C to 20°C or 59°F to 68°F (Table 1–8). Relative humidity also has a considerable effect on comfort since it is a measure of air’s ability to absorb moisture and thus it affects the amount of heat a body can dissipate by evaporation. High relative humidity slows down heat rejection by evaporation, especially at high temperatures, and low relative humidity speeds it up. The desirable level of *relative humidity* is the broad range of 30 to 70 percent, with 50 percent being the most desirable level. Most people at these conditions feel neither hot nor cold, and the body does not need to activate any of the defense mechanisms to maintain the normal body temperature (Fig. 1–60).

Another factor that has a major effect on thermal comfort is **excessive air motion** or **draft**, which causes undesired local cooling of the human body. Draft is identified by many as a most annoying factor in work places, automobiles, and airplanes. Experiencing discomfort by draft is most common among people wearing indoor clothing and doing light sedentary work, and least common among people with high activity levels. The air velocity should be kept below 9 m/min (30 ft/min) in winter and 15 m/min (50 ft/min) in summer to minimize discomfort by draft, especially when the air is cool. A low level of air motion is desirable as it removes the warm, moist air that builds around the body and replaces it with fresh air. Therefore, air motion should be strong enough to remove heat and moisture from the vicinity of the body, but gentle enough to be unnoticed. High speed air motion causes discomfort outdoors as well. For example, an environment at 10°C (50°F) with 48 km/h winds feels as cold as an environment at –7°C (20°F) with 3 km/h winds because of the chilling effect of the air motion (the wind-chill factor).

A comfort system should provide *uniform conditions* throughout the living space to avoid discomfort caused by nonuniformities such as *drafts*, *asymmetric thermal radiation*, *hot or cold floors*, and *vertical temperature stratification*. **Asymmetric thermal radiation** is caused by the *cold surfaces* of large windows, uninsulated walls, or cold products and the *warm surfaces* of gas or electric radiant heating panels on the walls or ceiling, solar-heated masonry walls or ceilings, and warm machinery. Asymmetric radiation causes discomfort by exposing different sides of the body to surfaces at different temperatures and thus to different heat loss or gain by radiation. A person whose left side is exposed to a cold window, for

The effect of clothing on the environment temperature that feels comfortable ( $1 \text{ clo} = 0.155 \text{ m}^2 \cdot ^\circ\text{C/W} = 0.880 \text{ ft}^2 \cdot ^\circ\text{F-h/Btu}$ ).

From ASHRAE Standard 55-1981

**FIGURE 1-60**

A thermally comfortable environment.

example, will feel like heat is being drained from that side of his or her body (Fig. 1-61). For thermal comfort, the radiant temperature asymmetry should not exceed  $5^\circ\text{C}$  in the vertical direction and  $10^\circ\text{C}$  in the horizontal direction. The unpleasant effect of radiation asymmetry can be minimized by properly sizing and installing heating panels, using double-pane windows, and providing generous insulation at the walls and the roof.

Direct contact with **cold** or **hot floor surfaces** also causes localized discomfort in the feet. The temperature of the floor depends on the way it is *constructed* (being directly on the ground or on top of a heated room, being made of wood or concrete, the use of insulation, etc.) as well as the *floor covering used* such as pads, carpets, rugs, and linoleum. A floor temperature of 23 to  $25^\circ\text{C}$  is found to be comfortable to most people. The floor asymmetry loses its significance for people with footwear. An effective and economical way of raising the floor temperature is to use radiant heating panels instead of turning the thermostat up. Another non-uniform condition that causes discomfort is **temperature stratification** in a room that exposes the head and the feet to different temperatures. For thermal comfort, the temperature difference between the head and foot levels should not exceed  $5^\circ\text{C}$ . This effect can be minimized by using destratification fans.

It should be noted that no thermal environment will please everyone. No matter what we do, some people will express some discomfort. The thermal comfort zone is based on a 90 percent acceptance rate. That is, an environment is deemed comfortable if only 10 percent of the people are dissatisfied with it. Metabolism decreases somewhat with *age*, but it has no effect on the comfort zone. Research indicates that there is no appreciable difference between the environments preferred by old and young people. Experiments also show that *men* and *women* prefer almost the same environment. The metabolism rate of women is somewhat lower, but this is compensated by their slightly lower skin temperature, lower surface area, and lower evaporative loss as compared with men. Also, there is no significant variation in the comfort zone from one part of the world to another and from winter to summer even though large environmental temperature differences may exist in different parts of the world and even within the same region during different seasons (Table 1-8). Therefore, the same thermal comfort conditions can be used *throughout the world* in any season. Also, people cannot *acclimatize* themselves to prefer different comfort conditions.

In a **cold environment**, the rate of heat loss from the body may exceed the rate of metabolic heat generation. Average specific heat of the human body is  $3.49 \text{ kJ/kg} \cdot ^\circ\text{C}$ , and thus each  $1^\circ\text{C}$  drop in body temperature corresponds to a deficit of 244 kJ in body heat content for an average 70-kg man. A drop of  $0.5^\circ\text{C}$  in mean body temperature causes noticeable but acceptable discomfort. A drop of  $2.6^\circ\text{C}$  causes extreme discomfort. A sleeping person wakes up when his or her mean body temperature drops by  $1.3^\circ\text{C}$  (which normally shows up as a  $0.5^\circ\text{C}$  drop in the core body and

3°C in the skin area). The drop of core body temperature below 35°C may damage the body temperature regulation mechanism, while a core below 28°C may be fatal and a drop to 23°C will be fatal (Table 1–8). Sedentary people reported to feel *comfortable* at a *mean skin temperature* of 33.3°C, *uncomfortably cold* at 31°C, *shivering cold* at 30°C, and *extremely cold* at 29°C. People doing heavy work reported to feel comfortable at much lower temperatures, which shows that the activity level affects human performance and comfort. The extremities of the body such as hands and feet are most easily affected by cold weather, and their temperature is a better indication of comfort and performance. A hand-skin temperature of 20°C is perceived to be uncomfortably cold, 15°C to be extremely cold, and 5°C to be painfully cold. Useful work can be performed by hands without difficulty as long as the skin temperature of fingers remains above 16°C (ASHRAE *Handbook of Fundamentals*, Chapter 8).

The first line of defense of the body against excessive heat loss in a cold environment is *to reduce the skin temperature* and thus the rate of heat loss from the skin by constricting the arteries, thus decreasing the blood flow to the skin. This measure decreases the temperature of the tissues subjacent to the skin, but maintains the core body temperature. The next preventive measure is increasing the rate of *metabolic heat generation* in the body by *shivering*, unless the person does it voluntarily by increasing his or her level of activity or puts on additional clothing. Shivering begins slowly in small muscle groups and may double the rate of metabolic heat production of the body at its initial stages. In the extreme case of total body shivering, the rate of heat production may reach six times the resting levels (Fig. 1–62). If this measure also proves inadequate, the core body temperature starts *falling*. Body parts furthest away from the core such as the hands and feet are at greatest danger for tissue damage.

In **hot environments**, the rate of heat loss from the body may drop below the metabolic heat generation rate. This time the body activates the opposite mechanisms. First the body increases the *blood flow* and thus heat transport to the skin, causing the temperature of the skin and the subjacent tissues to rise and approach the deep body temperature. Under extreme heat conditions, the *heart rate* may reach 150 beats per minute in order to maintain adequate blood supply to the brain and the skin. At higher heart rates, the *volumetric efficiency* of the heart drops because of the very short time between the beats to fill the heart with blood, and the oxygen supply to the skin and more importantly to the brain drops. This causes the person to faint as a result of *heat exhaustion*. Dehydration makes the problem worse. A similar thing happens when a person working very hard for a long time stops suddenly and becomes sedentary. The blood that has flooded the skin and other tissues that were in use (e.g., muscles) has difficulty returning to the heart in this case since the relaxed muscles no longer force the blood back to the heart, and thus there is less blood available for pumping to the brain. Therefore, a “cooling down” period after exercising is just as important as a “warming up” period.

**FIGURE 1–61**

Cold surfaces cause excessive heat loss from the body by radiation, and thus discomfort on that side of the body.

**FIGURE 1–62**

The rate of metabolic heat generation may go up by six times the resting level during total body shivering in cold weather.

**FIGURE 1-63**

In hot environments, a body can dissipate a large amount of metabolic heat by sweating since the sweat absorbs the body heat and evaporates.

The next line of defense is releasing water from sweat glands and resorting to *evaporative cooling*, unless the person removes some clothing and reduces the activity level (Fig. 1-63). The body can maintain its core temperature at 37°C in this evaporative cooling mode indefinitely, even in environments at higher temperatures (as high as 200°C during military endurance tests), if the person drinks plenty of liquids to replenish his or her water reserves and the ambient air is sufficiently dry to allow the sweat to evaporate instead of rolling down the skin. If this measure proves inadequate, the body will have to start absorbing the metabolic heat and the deep body temperature will rise. A person can tolerate a temperature rise of 1.4°C without major discomfort but may *collapse* when the temperature rise reaches 2.8°C. People feel sluggish and their efficiency drops considerably when the core body temperature rises above 39°C. A core temperature above 41°C may damage most innate proteins, resulting in cessation of sweating, increased heat production by shivering, and a *heat stroke* with irreversible and life-threatening damage. Death can occur above 43°C (Table 1-8).

A surface temperature of 46°C causes pain on the skin. Therefore, direct contact with a metal block at this temperature or above is painful. However, a person can stay in a room at 100°C for up to 30 min without any damage or pain on the skin because of the convective resistance at the skin surface and evaporative cooling. We can even put our hands into an oven at 200°C for a short time without getting burned.

The processes that have been described in the previous few paragraphs fall into a category of physiology termed *thermoregulation*. The body has mechanisms to act as a thermostat, when the core body temperature deviates from the normal resting value. With an increase in temperature, skin blood vessels dilate and sweat is produced, while a decrease in temperature induces skin blood vessel constriction and shivering. It is also important to point out that not all living beings use these same mechanisms to regulate the temperature of their bodies. A dog, which is an endotherm similar to humans, loses heat by panting. Ectotherms, must derive heat from their surrounding environment, such as a lizard warming up by standing on a sun heated rock. It is also important to note that the metabolisms of endotherms are not dependent on the surrounding environment, whereas ectotherm metabolism is highly dependent on the environment. Thermoregulation in the human body is achieved by keeping a tight balance between heat gain and heat loss. The “Bioheat Transfer Equation” introduced in Chapter 3 is used to calculate the heat transfer between a human body and its surroundings.

Thermoregulation can be adjusted by both behavioral changes and physiological changes. We have discussed many behavioral changes, such as relocating to a more desirable environment within the structure or putting on more clothing. Physiological changes include blood vessel diameter changes and the production of sweat. However, under normal conditions, few of these changes are needed because of the efficient organization of

arteries and veins; they are arranged as a counter-current heat exchanger (for more information refer to Chapter 11 Topic of Special Interest “The Human Cardiovascular System as a Counter-Current Heat Exchanger”). The primary function of this counter-current heat exchanger in the human body is to minimize the loss of heat to the external environment. In nearly all systems, an artery, which delivers blood to a limb, is located directly adjacent to a vein, which returns blood to the core of the body. Recall that the extremities may be at a very different temperature than the core and this would be manifested directly in the blood returning from the limb. However, since the vein runs adjacent to an artery, there is a continual conduction of heat along the entire blood vessel length from the artery to the vein. This acts to prevent cool blood from entering into the core of the body.

Another factor that affects thermal comfort, health, and productivity is **ventilation**. Fresh outdoor air can be provided to a building *naturally* by doing nothing, or *forcefully* by a mechanical ventilation system. In the first case, which is the norm in residential buildings, the necessary ventilation is provided by *infiltration through cracks and leaks* in the living space and by the opening of the windows and doors. The additional ventilation needed in the bathrooms and kitchens is provided by *air vents with dampers* or *exhaust fans*. With this kind of uncontrolled ventilation, however, the fresh air supply will be either too high, wasting energy, or too low, causing poor indoor air quality. But the current practice is not likely to change for residential buildings since there is not a public outcry for energy waste or air quality, and thus it is difficult to justify the cost and complexity of mechanical ventilation systems.

Mechanical ventilation systems are part of any heating and air conditioning system in *commercial buildings*, providing the necessary amount of fresh outdoor air and distributing it uniformly throughout the building. This is not surprising since many rooms in large commercial buildings have no windows and thus rely on mechanical ventilation. Even the rooms with windows are in the same situation since the windows are tightly sealed and cannot be opened in most buildings. It is not a good idea to oversize the ventilation system just to be on the “safe side” since exhausting the heated or cooled indoor air wastes energy. On the other hand, reducing the ventilation rates below the required minimum to conserve energy should also be avoided so that the indoor air quality can be maintained at the required levels. The minimum fresh air ventilation requirements are listed in Table 1–9. The values are based on controlling the CO<sub>2</sub> and other contaminants with an adequate margin of safety, which requires each person be supplied with at least 7.5 L/s (15 ft<sup>3</sup>/min) of fresh air.

Another function of the mechanical ventilation system is to **clean** the air by filtering it as it enters the building. Various types of filters are available for this purpose, depending on the cleanliness requirements and the allowable pressure drop.

**TABLE 1–9**

Minimum fresh air requirements in buildings (from ASHRAE Standard 62-1989)

## SUMMARY

In this chapter, the basics of heat transfer are introduced and discussed. The science of *thermodynamics* deals with the amount of heat transfer as a system undergoes a process from one equilibrium state to another, whereas the science of *heat transfer* deals with the rate of heat transfer, which is the main focus of interest in the design and evaluation of heat transfer equipment. The sum of all forms of energy of a system is called *total energy*, and it includes the internal, kinetic, and potential energies. The *internal energy* represents the molecular energy of a system, and it consists of sensible, latent, chemical, and nuclear forms. The sensible and latent forms of internal energy can be transferred from one medium to another as a result of a temperature difference, and are referred to as *heat* or *thermal energy*. Thus, *heat transfer* is the exchange of the sensible and latent forms of internal energy between two mediums as a result of a temperature difference. The amount of heat transferred per unit time is called *heat transfer rate* and is denoted by  $\dot{Q}$ . The rate of heat transfer per unit area is called *heat flux*,  $\dot{q}$ .

A system of fixed mass is called a *closed system*, and a system that involves mass transfer across its boundaries is called an *open system* or *control volume*. The *first law of thermodynamics* or the *energy balance* for any system undergoing any process can be expressed as

$$E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$$

When a stationary closed system involves heat transfer only and no work interactions across its boundary, the energy balance relation reduces to

$$Q = mc_v \Delta T$$

where  $Q$  is the amount of net heat transfer to or from the system. When heat is transferred at a constant rate of  $\dot{Q}$ , the amount of heat transfer during a time interval  $\Delta t$  can be determined from  $Q = \dot{Q}\Delta t$ .

Under steady conditions and in the absence of any work interactions, the conservation of energy relation for a control volume with one inlet and one exit with negligible changes in kinetic and potential energies can be expressed as

$$\dot{Q} = \dot{m}c_p \Delta T$$

where  $\dot{m} = \rho V A_c$  is the mass flow rate and  $\dot{Q}$  is the rate of net heat transfer into or out of the control volume.

Heat can be transferred in three different modes: conduction, convection, and radiation. *Conduction* is the transfer of heat from the more energetic particles of a substance to the adjacent less energetic ones as a result of interactions between

the particles, and is expressed by *Fourier's law of heat conduction* as

$$\dot{Q}_{\text{cond}} = -kA \frac{dT}{dx}$$

where  $k$  is the *thermal conductivity* of the material in W/m·K or Btu/h·ft·R,  $A$  is the *area* normal to the direction of heat transfer, and  $dT/dx$  is the *temperature gradient*. The magnitude of the rate of heat conduction across a plane layer of thickness  $L$  is given by

$$\dot{Q}_{\text{cond}} = kA \frac{\Delta T}{L}$$

where  $\Delta T$  is the temperature difference across the layer.

*Convection* is the mode of heat transfer between a solid surface and the adjacent liquid or gas that is in motion, and involves the combined effects of conduction and fluid motion. The rate of convection heat transfer is expressed by *Newton's law of cooling* as

$$\dot{Q}_{\text{convection}} = hA_s (T_s - T_\infty)$$

where  $h$  is the *convection heat transfer coefficient* in W/m<sup>2</sup>·K or Btu/h·ft<sup>2</sup>·R,  $A_s$  is the *surface area* through which convection heat transfer takes place,  $T_s$  is the *surface temperature*, and  $T_\infty$  is the *temperature of the fluid* sufficiently far from the surface.

*Radiation* is the energy emitted by matter in the form of electromagnetic waves (or photons) as a result of the changes in the electronic configurations of the atoms or molecules. The maximum rate of radiation that can be emitted from a surface at a thermodynamic temperature  $T_s$  is given by the *Stefan-Boltzmann law* as  $\dot{Q}_{\text{emit, max}} = \sigma A_s T_s^4$ , where  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4$  or  $0.1714 \times 10^{-8} \text{ Btu/h}\cdot\text{ft}^2\cdot\text{R}^4$  is the *Stefan-Boltzmann constant*.

When a surface of emissivity  $\varepsilon$  and surface area  $A_s$  at a temperature  $T_s$  is completely enclosed by a much larger (or black) surface at a temperature  $T_{\text{surr}}$  separated by a gas (such as air) that does not intervene with radiation, the net rate of radiation heat transfer between these two surfaces is given by

$$\dot{Q}_{\text{rad}} = \varepsilon \sigma A_s (T_s^4 - T_{\text{surr}}^4)$$

In this case, the emissivity ( $\varepsilon$ ) and the surface area of the surrounding surface do not have any effect on the net radiation heat transfer.

The rate at which a surface absorbs radiation is determined from  $\dot{Q}_{\text{absorbed}} = \alpha \dot{Q}_{\text{incident}}$  where  $\dot{Q}_{\text{incident}}$  is the rate at which radiation is incident on the surface and  $\alpha$  is the absorptivity of the surface.

## PROBLEMS\*

### Thermodynamics and Heat Transfer

**1–1C** How does the science of heat transfer differ from the science of thermodynamics?

**1–2C** What is the driving force for (a) heat transfer, (b) electric current flow, and (c) fluid flow?

**1–3C** What is the caloric theory? When and why was it abandoned?

**1–4C** How do rating problems in heat transfer differ from the sizing problems?

**1–5C** What is the difference between the analytical and experimental approach to heat transfer? Discuss the advantages and disadvantages of each approach.

**1–6C** How do the differential equations in the study of a physical problem arise?

**1–7C** What is the importance of modeling in engineering? How are the mathematical models for engineering processes prepared?

**1–8C** When modeling an engineering process, how is the right choice made between a simple but crude and a complex but accurate model? Is the complex model necessarily a better choice since it is more accurate?

**1–9C** On a hot summer day, a student turns his fan on when he leaves his room in the morning. When he returns in the evening, will his room be warmer or cooler than the neighboring rooms? Why? Assume all the doors and windows are kept closed.

**1–10C** Consider two identical rooms, one with a refrigerator in it and the other without one. If all the doors and windows are

closed, will the room that contains the refrigerator be cooler or warmer than the other room? Why?

**1–11C** An ideal gas is heated from 50°C to 80°C (a) at constant volume and (b) at constant pressure. For which case do you think the energy required will be greater? Why?

**1–12C** How are heat, internal energy, and thermal energy related to each other?

**1–13C** What is heat flux? How is it related to the heat transfer rate?

**1–14C** What are the mechanisms of energy transfer to a closed system? How is heat transfer distinguished from the other forms of energy transfer?

**1–15** Consider a 150-W incandescent lamp. The filament of the lamp is 5-cm long and has a diameter of 0.5 mm. The diameter of the glass bulb of the lamp is 8 cm. Determine the heat flux, in  $\text{W/m}^2$ , (a) on the surface of the filament and (b) on the surface of the glass bulb, and (c) calculate how much it will cost per year to keep that lamp on for eight hours a day every day if the unit cost of electricity is \$0.08/kWh.

FIGURE P1–15

\* Problems designated by a “C” are concept questions, and students are encouraged to answer them all. Problems designated by an “E” are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature and are intended to be solved with an equation solver such as EES. Problems with the icon are Prevention through Design problems.

**1-16E** A logic chip used in a computer dissipates 3 W of power in an environment at 120°F, and has a heat transfer surface area of 0.08 in<sup>2</sup>. Assuming the heat transfer from the surface to be uniform, determine (a) the amount of heat this chip dissipates during an eight-hour work day, in kWh, and (b) the heat flux on the surface of the chip, in W/in<sup>2</sup>.

**1-17** A 15-cm-diameter aluminum ball is to be heated from 80°C to an average temperature of 200°C. Taking the average density and specific heat of aluminum in this temperature range to be  $\rho = 2700 \text{ kg/m}^3$  and  $c_p = 0.90 \text{ kJ/kg-K}$ , respectively, determine the amount of energy that needs to be transferred to the aluminum ball. *Answer: 515 kJ*

**1-18** A rigid closed tank is filled with 1 metric ton of liquid ammonia and is exposed to the sun. At 6 am, the liquid ammonia is at a temperature of 4°C. By 3 pm, the temperature of the liquid ammonia has increased by 2°C. Determine the amount of heat energy that has been added to the liquid ammonia.

**1-19** In a manufacturing plant, AISI 1010 carbon steel strips ( $\rho = 7832 \text{ kg/m}^3$ ) of 2 mm thick and 3 cm wide are conveyed into a chamber at a constant speed to be cooled from 527°C to 127°C. Determine the speed of a steel strip being conveyed inside the chamber, if the rate of heat being removed from a steel strip inside the chamber is 100 kW.

**1-20E** A 60-gallon water heater is initially filled with water at 50°F. Determine how much energy (in Btu) needs to be transferred to the water to raise its temperature to 120°F. Evaluate the water properties at an average water temperature of 85°F.

**1-21** Consider a house with a floor space of 200 m<sup>2</sup> and an average height of 3 m at sea level, where the standard atmospheric pressure is 101.3 kPa. Initially the house is at a uniform temperature of 10°C. Now the electric heater is turned on, and the heater runs until the air temperature in the house rises to an average value of 22°C. Determine how much heat is absorbed by the air assuming some air escapes through the cracks as the heated air in the house expands at constant pressure. Also, determine the cost of this heat if the unit cost of electricity in that area is \$0.075/kWh.

**1-22** Infiltration of cold air into a warm house during winter through the cracks around doors, windows, and other openings is a major source of energy loss since the cold air that enters needs to be heated to the room temperature. The infiltration is often expressed in terms of ACH (air changes per hour). An ACH of 2 indicates that the entire air in the house is replaced twice every hour by the cold air outside.

Consider an electrically heated house that has a floor space of 150 m<sup>2</sup> and an average height of 3 m at 1000 m elevation, where the standard atmospheric pressure is 89.6 kPa. The house is maintained at a temperature of 22°C, and the infiltration losses are estimated to amount to 0.7 ACH. Assuming the pressure and the temperature in the house remain constant, determine the amount of energy loss from the house due to infiltration for a day during which the average outdoor temperature is 5°C. Also, determine the cost of this energy

loss for that day if the unit cost of electricity in that area is \$0.082/kWh. *Answers: 40.4 kWh/day, \$3.31/day*

**1-23** Water is heated in an insulated, constant diameter tube by a 5-kW electric resistance heater. If the water enters the heater steadily at 15°C and leaves at 60°C, determine the mass flow rate of water.

FIGURE P1-23

**1-24** Liquid ethanol is a flammable fluid and can release vapors that form explosive mixtures at temperatures above its flashpoint at 16.6°C. In a chemical plant, liquid ethanol ( $c_p = 2.44 \text{ kJ/kg-K}$ ,  $\rho = 789 \text{ kg/m}^3$ ) is being transported in a pipe with an inside diameter of 5 cm. The pipe is located in a hot area with the presence of ignition source, where an estimated 20 kW of heat is added to the ethanol. Your task, as an engineer, is to design a pumping system to transport the ethanol safely and to prevent fire hazard. If the inlet temperature of the ethanol is 10°C, determine the volume flow rate that is necessary to keep the temperature of the ethanol in the pipe below its flashpoint.

FIGURE P1-24

**1-25** In many manufacturing plants, individuals are often working around high temperature surfaces. Exposed hot surfaces that are potential for thermal burns on human skin tissue are considered to be hazards in the workplace. Metallic surface of temperature above 70°C is considered extremely high temperature in the context of thermal burn, where skin tissue damage can occur instantaneously upon contact with the hot surface. Consider an AISI 1010 carbon steel strip ( $\rho = 7832 \text{ kg/m}^3$ ) of 2 mm thick and 3 cm wide that is conveyed into a chamber to be cooled at a constant speed of 1 m/s. The steel strip enters the cooling chamber at 597°C. Determine the amount of heat rate that needed to be removed so that the steel strip exits the chamber at 47°C to avoid instantaneous thermal burn upon accidental contact with skin tissue. Discuss how the conveyance speed can affect the heat rate needed to be removed from the steel strip in the cooling chamber.

FIGURE P1-25

**1–26** 1.2 kg of liquid water initially at 15°C is to be heated to 95°C in a teapot equipped with a 1200-W electric heating element inside. The teapot is 0.5 kg and has an average specific heat of 0.7 kJ/kg·K. Taking the specific heat of water to be 4.18 kJ/kg·K and disregarding any heat loss from the teapot, determine how long it will take for the water to be heated.

FIGURE P1–26

**1–27** A room is heated by a baseboard resistance heater. When the heat losses from the room on a winter day amount to 9000 kJ/h, it is observed that the air temperature in the room remains constant even though the heater operates continuously. Determine the power rating of the heater, in kW.

**1–28** A house has an electric heating system that consists of a 300-W fan and an electric resistance heating element placed in a duct. Air flows steadily through the duct at a rate of 0.6 kg/s and experiences a temperature rise of 5°C. The rate of heat loss from the air in the duct is estimated to be 250 W. Determine the power rating of the electric resistance heating element.

**1–29** A 5-m × 6-m × 8-m room is to be heated by an electrical resistance heater placed in a short duct in the room. Initially, the room is at 15°C, and the local atmospheric pressure is 98 kPa. The room is losing heat steadily to the outside at a rate of 200 kJ/min. A 300-W fan circulates the air steadily through the duct and the electric heater at an average mass flow rate of 50 kg/min. The duct can be assumed to be adiabatic, and there is no air leaking in or out of the room. If it takes 18 minutes for the room air to reach an average temperature of 25°C, find (a) the power rating of the electric heater and (b) the temperature rise that the air experiences each time it passes through the heater.

**1–30** The ducts of an air heating system pass through an unheated area. As a result of heat losses, the temperature of the air in the duct drops by 3°C. If the mass flow rate of air is 90 kg/min, determine the rate of heat loss from the air to the cold environment.

**1–31** A hair dryer is basically a duct in which a few layers of electric resistors are placed. A small fan pulls the air in and forces it to flow over the resistors where it is heated. Air enters a 900-W hair dryer at 100 kPa and 25°C, and leaves at 50°C.

The cross-sectional area of the hair dryer at the exit is 60 cm<sup>2</sup>. Neglecting the power consumed by the fan and the heat losses through the walls of the hair dryer, determine (a) the volume flow rate of air at the inlet and (b) the velocity of the air at the exit.

FIGURE P1–31

**1–32E** Air enters the duct of an air-conditioning system at 15 psia and 50°F at a volume flow rate of 450 ft<sup>3</sup>/min. The diameter of the duct is 10 inches and heat is transferred to the air in the duct from the surroundings at a rate of 2 Btu/s. Determine (a) the velocity of the air at the duct inlet and (b) the temperature of the air at the exit.

Answers: (a) 825 ft/min, (b) 64°F

### Heat Transfer Mechanisms

**1–33C** Define thermal conductivity and explain its significance in heat transfer.

**1–34C** Judging from its unit W/m·K, can we define thermal conductivity of a material as the rate of heat transfer through the material per unit thickness per unit temperature difference? Explain.

**1–35C** Which is a better heat conductor, diamond or silver?

**1–36C** How do the thermal conductivity of gases and liquids vary with temperature?

**1–37C** Why is the thermal conductivity of superinsulation orders of magnitude lower than the thermal conductivity of ordinary insulation?

**1–38C** Why do we characterize the heat conduction ability of insulators in terms of their apparent thermal conductivity instead of the ordinary thermal conductivity?

**1–39C** Consider an alloy of two metals whose thermal conductivities are  $k_1$  and  $k_2$ . Will the thermal conductivity of the alloy be less than  $k_1$ , greater than  $k_2$ , or between  $k_1$  and  $k_2$ ?

**1–40C** What are the mechanisms of heat transfer? How are they distinguished from each other?

**1–41C** Write down the expressions for the physical laws that govern each mode of heat transfer, and identify the variables involved in each relation.

**1–42C** How does heat conduction differ from convection?

**1–43C** Does any of the energy of the sun reach the earth by conduction or convection?

**1-44C** How does forced convection differ from natural convection?

**1-45C** What is the physical mechanism of heat conduction in a solid, a liquid, and a gas?

**1-46C** Consider heat transfer through a windowless wall of a house on a winter day. Discuss the parameters that affect the rate of heat conduction through the wall.

**1-47C** Consider heat loss through the two walls of a house on a winter night. The walls are identical, except that one of them has a tightly fit glass window. Through which wall will the house lose more heat? Explain.

**1-48C** Consider two houses that are identical, except that the walls are built using bricks in one house, and wood in the other. If the walls of the brick house are twice as thick, which house do you think will be more energy efficient?

**1-49C** Consider two walls of a house that are identical except that one is made of 10-cm-thick wood, while the other is made of 25-cm-thick brick. Through which wall will the house lose more heat in winter?

**1-50C** Define emissivity and absorptivity. What is Kirchhoff's law of radiation?

**1-51C** What is a blackbody? How do real bodies differ from blackbodies?

**1-52** A wood slab with a thickness of 0.05 m is subjected to a heat flux of  $40 \text{ W/m}^2$ . The left and right surface temperatures of the wood slab are kept at constant temperatures of  $40^\circ\text{C}$  and  $20^\circ\text{C}$ , respectively. What is the thermal conductivity of the wood slab?

**1-53** The inner and outer surfaces of a  $4\text{-m} \times 7\text{-m}$  brick wall of thickness 30 cm and thermal conductivity 0.69 W/m-K are maintained at temperatures of  $26^\circ\text{C}$  and  $8^\circ\text{C}$ , respectively. Determine the rate of heat transfer through the wall, in W.

FIGURE P1-53

**1-54** The inner and outer surfaces of a 0.5-cm thick  $2\text{-m} \times 2\text{-m}$  window glass in winter are  $10^\circ\text{C}$  and  $3^\circ\text{C}$ , respectively. If the

thermal conductivity of the glass is  $0.78 \text{ W/m}\cdot\text{K}$ , determine the amount of heat loss through the glass over a period of 5 h. What would your answer be if the glass were 1 cm thick?

Answers: 78.6 MJ, 39.3 MJ

**1-55** Reconsider Prob. 1-54. Using EES (or other) software, plot the amount of heat loss through the glass as a function of the window glass thickness in the range of 0.1 cm to 1.0 cm. Discuss the results.

**1-56** An aluminum pan whose thermal conductivity is  $237 \text{ W/m}\cdot\text{K}$  has a flat bottom with diameter 15 cm and thickness 0.4 cm. Heat is transferred steadily to boiling water in the pan through its bottom at a rate of 1400 W. If the inner surface of the bottom of the pan is at  $105^\circ\text{C}$ , determine the temperature of the outer surface of the bottom of the pan.

FIGURE P1-56

**1-57E** The north wall of an electrically heated home is 20 ft long, 10 ft high, and 1 ft thick, and is made of brick whose thermal conductivity is  $k = 0.42 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ . On a certain winter night, the temperatures of the inner and the outer surfaces of the wall are measured to be at about  $62^\circ\text{F}$  and  $25^\circ\text{F}$ , respectively, for a period of 8 h. Determine (a) the rate of heat loss through the wall that night and (b) the cost of that heat loss to the home owner if the cost of electricity is \$0.07/kWh.

**1-58** In a certain experiment, cylindrical samples of diameter 4 cm and length 7 cm are used (see Fig. 1-32). The two thermocouples in each sample are placed 3 cm apart. After initial transients, the electric heater is observed to draw 0.6 A at 110 V, and both differential thermometers read a temperature difference of  $8^\circ\text{C}$ . Determine the thermal conductivity of the sample. Answer:  $98.5 \text{ W/m}\cdot\text{K}$

**1-59** One way of measuring the thermal conductivity of a material is to sandwich an electric thermofoil heater between two identical rectangular samples of the material and to heavily insulate the four outer edges, as shown in the figure. Thermocouples attached to the inner and outer surfaces of the samples record the temperatures.

During an experiment, two 0.5-cm thick samples  $10 \text{ cm} \times 10 \text{ cm}$  in size are used. When steady operation is reached, the heater is observed to draw 25 W of electric power, and the temperature of each sample is observed to drop from  $82^\circ\text{C}$  at the

inner surface to 74°C at the outer surface. Determine the thermal conductivity of the material at the average temperature.

**FIGURE P1-59**

- 1-60 PTD** Silicon wafer is susceptible to warping when the wafer is subjected to temperature difference across its thickness. Thus, steps needed to be taken to prevent the temperature gradient across the wafer thickness from getting large. As an engineer in a semiconductor company, your task is to determine the maximum allowable heat flux on the bottom surface of the wafer, while maintaining the upper surface temperature at 27°C. To prevent the wafer from warping, the temperature difference across its thickness of 500 μm cannot exceed 1°C.

**FIGURE P1-60**

- 1-61** A concrete wall with a surface area of 20 m<sup>2</sup> and a thickness of 0.30 m separates conditioned room air from ambient air. The temperature of the inner surface of the wall ( $T_1$ ) is maintained at 25°C. (a) Determine the heat loss  $\dot{Q}$  (W) through the concrete wall for three thermal conductivity values of (0.75, 1, and 1.25 W/m·K) and outer wall surface temperatures of  $T_2 = -15, -10, -5, 0, 5, 10, 15, 20, 25, 30, \text{ and } 38^\circ\text{C}$  (a total of 11 data points for each thermal conductivity value). Tabulate the results for all three cases in one table. Also provide a computer generated graph [Heat loss,  $\dot{Q}$  (W) vs. Outside wall temperature,  $T_2$  ( $^\circ\text{C}$ )] for the display of your results. The results for all three cases should be plotted on the same graph. (b) Discuss your results for the three cases.

- 1-62** A hollow spherical iron container with outer diameter 20 cm and thickness 0.2 cm is filled with iced water at 0°C. If the outer surface temperature is 5°C, determine the approximate rate of heat loss from the sphere, in kW, and the rate at

which ice melts in the container. The heat of fusion of water is 333.7 kJ/kg.

**FIGURE P1-62**

- 1-63 EES** Reconsider Prob. 1-62. Using EES (or other) software, plot the rate at which ice melts as a function of the container thickness in the range of 0.1 cm to 1.0 cm. Discuss the results.

- 1-64E** The inner and outer glasses of a 4-ft × 4-ft double-pane window are at 60°F and 48°F, respectively. If the 0.25-in. space between the two glasses is filled with still air, determine the rate of heat transfer through the window.

*Answer: 131 Btu/h*

- 1-65E** An engineer who is working on the heat transfer analysis of a house in English units needs the convection heat transfer coefficient on the outer surface of the house. But the only value he can find from his handbooks is 22 W/m<sup>2</sup>·K, which is in SI units. The engineer does not have a direct conversion factor between the two unit systems for the convection heat transfer coefficient. Using the conversion factors between W and Btu/h, m and ft, and °C and °F, express the given convection heat transfer coefficient in Btu/h·ft<sup>2</sup>·°F. *Answer: 3.87 Btu/h·ft<sup>2</sup>·°F*

- 1-66** Air at 20°C with a convection heat transfer coefficient of 20 W/m<sup>2</sup>·K blows over a pond. The surface temperature of the pond is at 40°C. Determine the heat flux between the surface of the pond and the air.

- 1-67** Four power transistors, each dissipating 12 W, are mounted on a thin vertical aluminum plate 22 cm × 22 cm in size. The heat generated by the transistors is to be dissipated by both surfaces of the plate to the surrounding air at 25°C, which is blown over the plate by a fan. The entire plate can be assumed to be nearly isothermal, and the exposed surface area of the transistor can be taken to be equal to its base area. If the average convection heat transfer coefficient is 25 W/m<sup>2</sup>·K, determine the temperature of the aluminum plate. Disregard any radiation effects.

- 1-68** In a power plant, pipes transporting superheated vapor are very common. Superheated vapor is flowing at a rate of 0.3 kg/s inside a pipe with 5 cm in diameter and 10 m in length. The pipe is located in a power plant at 20°C, and has a uniform

pipe surface temperature of  $100^\circ\text{C}$ . If the temperature drop between the inlet and exit of the pipe is  $30^\circ\text{C}$ , and the specific heat of the vapor is  $2190 \text{ J/kg}\cdot\text{K}$ , determine the heat transfer coefficient as a result of convection between the pipe surface and the surrounding.

FIGURE P1-68

**1-69** An electric current of  $5 \text{ A}$  passing through a resistor has a measured voltage of  $6 \text{ V}$  across the resistor. The resistor is cylindrical with a diameter of  $2.5 \text{ cm}$  and length of  $15 \text{ cm}$ . The resistor has a uniform temperature of  $90^\circ\text{C}$  and the room air temperature is  $20^\circ\text{C}$ . Assuming that heat transfer by radiation is negligible, determine the heat transfer coefficient by convection.

**1-70** Hot air at  $80^\circ\text{C}$  is blown over a  $2\text{-m} \times 4\text{-m}$  flat surface at  $30^\circ\text{C}$ . If the average convection heat transfer coefficient is  $55 \text{ W/m}^2\cdot\text{K}$ , determine the rate of heat transfer from the air to the plate, in  $\text{kW}$ . *Answer: 22 kW*

**1-71** Reconsider Prob. 1-70. Using EES (or other) software, plot the rate of heat transfer as a function of the heat transfer coefficient in the range of  $20 \text{ W/m}^2\cdot\text{K}$  to  $100 \text{ W/m}^2\cdot\text{K}$ . Discuss the results.

**1-72** A  $5\text{-cm}$ -external-diameter,  $10\text{-m}$ -long hot-water pipe at  $80^\circ\text{C}$  is losing heat to the surrounding air at  $5^\circ\text{C}$  by natural convection with a heat transfer coefficient of  $25 \text{ W/m}^2\cdot\text{K}$ . Determine the rate of heat loss from the pipe by natural convection. *Answer: 2945 W*

**1-73** An AISI 316 stainless steel spherical container is used for storing chemicals undergoing exothermic reaction that provides a uniform heat flux of  $60 \text{ kW/m}^2$  to the container's inner surface. The container has an inner diameter of  $1 \text{ m}$  and a wall thickness of  $5 \text{ cm}$ . For safety reason to prevent thermal burn on individuals working around the container, it is necessary to keep the container's outer surface temperature below  $50^\circ\text{C}$ . If the ambient temperature is  $23^\circ\text{C}$ , determine the necessary convection heat transfer coefficient to keep the container's outer surface temperature below  $50^\circ\text{C}$ . Is the necessary convection heat transfer coefficient feasible with free convection of air? If not, discuss other option to prevent the container's outer surface temperature from causing thermal burn.

FIGURE P1-73

**1-74** A transistor with a height of  $0.4 \text{ cm}$  and a diameter of  $0.6 \text{ cm}$  is mounted on a circuit board. The transistor is cooled by air flowing over it with an average heat transfer coefficient of  $30 \text{ W/m}^2\cdot\text{K}$ . If the air temperature is  $55^\circ\text{C}$  and the transistor case temperature is not to exceed  $70^\circ\text{C}$ , determine the amount of power this transistor can dissipate safely. Disregard any heat transfer from the transistor base.

FIGURE P1-74

**1-75** Reconsider Prob. 1-74. Using EES (or other) software, plot the amount of power the transistor can dissipate safely as a function of the maximum case temperature in the range of  $60^\circ\text{C}$  to  $90^\circ\text{C}$ . Discuss the results.

**1-76E** A  $300\text{-ft}$ -long section of a steam pipe whose outer diameter is  $4 \text{ in}$  passes through an open space at  $50^\circ\text{F}$ . The average temperature of the outer surface of the pipe is measured to be  $280^\circ\text{F}$ , and the average heat transfer coefficient on that surface is determined to be  $6 \text{ Btu/h}\cdot\text{ft}^{2,0}\text{F}$ . Determine (a) the rate of heat loss from the steam pipe and (b) the annual cost of this energy loss if steam is generated in a natural gas furnace having an efficiency of 86 percent, and the price of natural gas is  $\$1.10/\text{therm}$  ( $1 \text{ therm} = 100,000 \text{ Btu}$ ).

*Answers: (a) 433,500 Btu/h, (b) \$48,600/yr*

**1-77** The boiling temperature of nitrogen at atmospheric pressure at sea level (1 atm) is  $-196^\circ\text{C}$ . Therefore, nitrogen is commonly used in low temperature scientific studies since

the temperature of liquid nitrogen in a tank open to the atmosphere remains constant at  $-196^{\circ}\text{C}$  until the liquid nitrogen in the tank is depleted. Any heat transfer to the tank results in the evaporation of some liquid nitrogen, which has a heat of vaporization of  $198 \text{ kJ/kg}$  and a density of  $810 \text{ kg/m}^3$  at 1 atm.

Consider a 4-m-diameter spherical tank initially filled with liquid nitrogen at 1 atm and  $-196^{\circ}\text{C}$ . The tank is exposed to  $20^{\circ}\text{C}$  ambient air with a heat transfer coefficient of  $25 \text{ W/m}^2\cdot\text{K}$ . The temperature of the thin-shelled spherical tank is observed to be almost the same as the temperature of the nitrogen inside. Disregarding any radiation heat exchange, determine the rate of evaporation of the liquid nitrogen in the tank as a result of the heat transfer from the ambient air.

**FIGURE P1–77**

**1–78** Repeat Prob. 1–77 for liquid oxygen, which has a boiling temperature of  $-183^{\circ}\text{C}$ , a heat of vaporization of  $213 \text{ kJ/kg}$ , and a density of  $1140 \text{ kg/m}^3$  at 1 atm pressure.

**1–79** Reconsider Prob. 1–77. Using EES (or other) software, plot the rate of evaporation of liquid nitrogen as a function of the ambient air temperature in the range of  $0^{\circ}\text{C}$  to  $40^{\circ}\text{C}$ . Discuss the results.

**1–80** A series of experiments were conducted by passing  $40^{\circ}\text{C}$  air over a long 25 mm diameter cylinder with an embedded electrical heater. The objective of these experiments was to determine the power per unit length required ( $\dot{W}/L$ ) to maintain the surface temperature of the cylinder at  $300^{\circ}\text{C}$  for different air velocities ( $V$ ). The results of these experiments are given in the following table:

| $V(\text{m/s})$         | 1   | 2   | 4   | 8    | 12   |
|-------------------------|-----|-----|-----|------|------|
| $\dot{W}/L(\text{W/m})$ | 450 | 658 | 983 | 1507 | 1963 |

(a) Assuming a uniform temperature over the cylinder, negligible radiation between the cylinder surface and surroundings, and steady state conditions, determine the convection heat transfer coefficient ( $h$ ) for each velocity ( $V$ ). Plot the results in terms of  $h (\text{W/m}^2\cdot\text{K})$  vs.  $V (\text{m/s})$ . Provide a

computer generated graph for the display of your results and tabulate the data used for the graph.

- (b) Assume that the heat transfer coefficient and velocity can be expressed in the form of  $h = CV^n$ . Determine the values of the constants  $C$  and  $n$  from the results of part (a) by plotting  $h$  vs.  $V$  on log-log coordinates and choosing a  $C$  value that assures a match at  $V = 1 \text{ m/s}$  and then varying  $n$  to get the best fit.

**1–81** A 2.1-m-long, 0.2-cm-diameter electrical wire extends across a room that is maintained at  $20^{\circ}\text{C}$ . Heat is generated in the wire as a result of resistance heating, and the surface temperature of the wire is measured to be  $180^{\circ}\text{C}$  in steady operation. Also, the voltage drop and electric current through the wire are measured to be  $110 \text{ V}$  and  $3 \text{ A}$ , respectively. Disregarding any heat transfer by radiation, determine the convection heat transfer coefficient for heat transfer between the outer surface of the wire and the air in the room. *Answer: 156 W/m<sup>2</sup>·K*

**FIGURE P1–81**

**1–82** Reconsider Prob. 1–81. Using EES (or other) software, plot the convection heat transfer coefficient as a function of the wire surface temperature in the range of  $100^{\circ}\text{C}$  to  $300^{\circ}\text{C}$ . Discuss the results.

**1–83E** Using the conversion factors between W and Btu/h, m and ft, and K and R, express the Stefan–Boltzmann constant  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4$  in the English unit Btu/h·ft<sup>2</sup>·R<sup>4</sup>.

**1–84** The outer surface of a spacecraft in space has an emissivity of 0.8 and a solar absorptivity of 0.3. If solar radiation is incident on the spacecraft at a rate of  $950 \text{ W/m}^2$ , determine the surface temperature of the spacecraft when the radiation emitted equals the solar energy absorbed.

**1–85** Consider a person whose exposed surface area is  $1.7 \text{ m}^2$ , emissivity is 0.5, and surface temperature is  $32^{\circ}\text{C}$ . Determine the rate of heat loss from that person by radiation in a large room having walls at a temperature of (a)  $300 \text{ K}$  and (b)  $280 \text{ K}$ . *Answers: (a) 26.7 W, (b) 121 W*

**1–86** Consider a sealed 20-cm-high electronic box whose base dimensions are  $50 \text{ cm} \times 50 \text{ cm}$  placed in a vacuum chamber. The emissivity of the outer surface of the box is 0.95. If the electronic components in the box dissipate a total of  $120 \text{ W}$  of power and the outer surface temperature of the box is not to exceed  $55^{\circ}\text{C}$ , determine the temperature at which the surrounding surfaces must be kept if this box is to be cooled by radiation alone. Assume the heat transfer from the bottom surface of the box to the stand to be negligible.

FIGURE P1–86

**1–87** Two surfaces, one highly polished and the other heavily oxidized, are found to be emitting the same amount of energy per unit area. The highly polished surface has an emissivity of 0.1 at 1070°C, while the emissivity of the heavily oxidized surface is 0.78. Determine the temperature of the heavily oxidized surface.

**1–88** A spherical interplanetary probe, with a diameter of 2 m, is sent out into the solar system. The probe surface is made of material having an emissivity of 0.9 and an absorptivity of 0.1. Signals from the sensors monitoring the probe surface temperatures are indicating an average value of –40°C for a space temperature of 0 K. If the electronics inside the probe is generating heat at a rate of 100 W/m<sup>3</sup>, determine the incident radiation rate on the probe surface.

**1–89** An electronic package in the shape of a sphere with an outer diameter of 100 mm is placed in a large laboratory room. The surface emissivity of the package can assume three different values (0.2, 0.25, and 0.3). The walls of the room are maintained at a constant temperature of 77 K. The electronics in this package can only operate in the surface temperature range of  $40^\circ\text{C} \leq T_s \leq 85^\circ\text{C}$ . Determine the range of power dissipation ( $\dot{W}$ ) for the electronic package over this temperature range for the three surface emissivity values ( $\varepsilon$ ). Plot the results in terms of  $\dot{W}(\text{W})$  vs.  $T_s(\text{°C})$  for the three different values of emissivity over a surface temperature range of 40 to 85°C with temperature increments of 5°C (total of 10 data points for each  $\varepsilon$  value). Provide a computer generated graph for the display of your results and tabulate the data used for the graph. Comment on the results obtained.

### Simultaneous Heat Transfer Mechanisms

**1–90C** Can all three modes of heat transfer occur simultaneously (in parallel) in a medium?

**1–91C** Can a medium involve (a) conduction and convection, (b) conduction and radiation, or (c) convection and radiation simultaneously? Give examples for the “yes” answers.

**1–92C** The deep human body temperature of a healthy person remains constant at 37°C while the temperature and the

humidity of the environment change with time. Discuss the heat transfer mechanisms between the human body and the environment both in summer and winter, and explain how a person can keep cooler in summer and warmer in winter.

**1–93C** We often turn the fan on in summer to help us cool. Explain how a fan makes us feel cooler in the summer. Also explain why some people use ceiling fans also in winter.

**1–94** Consider a 20-cm thick granite wall with a thermal conductivity of 2.79 W/m·K. The temperature of the left surface is held constant at 50°C, whereas the right face is exposed to a flow of 22°C air with a convection heat transfer coefficient of 15 W/m<sup>2</sup>·K. Neglecting heat transfer by radiation, find the right wall surface temperature and the heat flux through the wall.

FIGURE P1–94

**1–95** A solid plate, with a thickness of 15 cm and a thermal conductivity of 80 W/m·K, is being cooled at the upper surface by air. The air temperature is 10°C, while the temperatures at the upper and lower surfaces of the plate are 50 and 60°C, respectively. Determine the convection heat transfer coefficient of air at the upper surface and discuss whether the value is reasonable or not for forced convection of air.

FIGURE P1–95

**1–96** Air at 20°C with a convection heat transfer coefficient of 25 W/m<sup>2</sup>·K blows over a horizontal steel hot plate ( $k = 43$  W/m·K). The surface area of the plate is 0.38 m<sup>2</sup> with a thickness of 2 cm. The plate surface is maintained at a constant temperature of  $T_s = 250^\circ\text{C}$  and the plate loses 300 W from its surface by radiation. Calculate the inside plate temperature ( $T_i$ ).

FIGURE P1–96

**1–97** An electronic package with a surface area of 1 m<sup>2</sup> placed in an orbiting space station is exposed to space. The electronics in this package dissipate all 1 kW of its power to the space through its exposed surface. The exposed surface has an emissivity of 1.0 and an absorptivity of 0.25. Determine the steady state exposed surface temperature of the electronic package (a) if the surface is exposed to a solar flux of 750 W/m<sup>2</sup>, and (b) if the surface is not exposed to the sun.

**1–98** Consider steady heat transfer between two large parallel plates at constant temperatures of  $T_1 = 290$  K and  $T_2 = 150$  K that are  $L = 2$  cm apart. Assuming the surfaces to be black (emissivity  $\epsilon = 1$ ), determine the rate of heat transfer between the plates per unit surface area assuming the gap between the plates is (a) filled with atmospheric air, (b) evacuated, (c) filled with fiberglass insulation, and (d) filled with superinsulation having an apparent thermal conductivity of 0.00015 W/m·K.

**1–99** Consider a person standing in a room at 18°C. Determine the total rate of heat transfer from this person if the exposed surface area and the skin temperature of the person are 1.7 m<sup>2</sup> and 32°C, respectively, and the convection heat transfer coefficient is 5 W/m<sup>2</sup>·K. Take the emissivity of the skin and the clothes to be 0.9, and assume the temperature of the inner surfaces of the room to be the same as the air temperature.

**1–100** The inner and outer surfaces of a 25-cm-thick wall in summer are at 27°C and 44°C, respectively. The outer surface of the wall exchanges heat by radiation with surrounding surfaces at 40°C, and convection with ambient air also at 40°C with a convection heat transfer coefficient of 8 W/m<sup>2</sup>·K. Solar radiation is incident on the surface at a rate of 150 W/m<sup>2</sup>. If both the emissivity and the solar absorptivity of the outer surface are 0.8, determine the effective thermal conductivity of the wall.

FIGURE P1–100

**1–101E** A 2-in-diameter spherical ball whose surface is maintained at a temperature of 170°F is suspended in the middle of a room at 70°F. If the convection heat transfer coefficient is 15 Btu/h·ft<sup>2</sup>·°F and the emissivity of the surface is 0.8, determine the total rate of heat transfer from the ball.

**1–102** An 800-W iron is left on the iron board with its base exposed to the air at 20°C. The convection heat transfer coefficient between the base surface and the surrounding air is 35 W/m<sup>2</sup>·K. If the base has an emissivity of 0.6 and a surface area of 0.02 m<sup>2</sup>, determine the temperature of the base of the iron. *Answer: 601°C*

FIGURE P1–102

**1–103** A 3-m-internal-diameter spherical tank made of 1-cm-thick stainless steel is used to store iced water at 0°C. The tank is located outdoors at 25°C. Assuming the entire steel tank to be at 0°C and thus the thermal resistance of the tank to be negligible, determine (a) the rate of heat transfer to the iced water in the tank and (b) the amount of ice at 0°C that melts during a 24-hour period. The heat of fusion of water at atmospheric pressure is  $h_f = 333.7$  kJ/kg. The emissivity of the outer surface of the tank is 0.75, and the convection heat transfer coefficient on the outer surface can be taken to be 30 W/m<sup>2</sup>·K. Assume the average surrounding surface temperature for radiation exchange to be 15°C.

*Answers: (a) 23.1 kW, (b) 5980 kg*

- 1-104**  In the metal processing industry, heat treatment of metals is commonly done using electrically heated draw batch furnaces. Consider a furnace that is situated in a room with surrounding air temperature of  $30^\circ\text{C}$  and an average convection heat transfer coefficient of  $12 \text{ W/m}^2\cdot\text{K}$ . The furnace front is made of a steel plate with thickness of  $20 \text{ mm}$  and a thermal conductivity of  $25 \text{ W/m}\cdot\text{K}$ . The outer furnace front surface has an emissivity of  $0.23$ , and the inside surface is subjected to a heat flux of  $8 \text{ kW/m}^2$ . Determine the outside surface temperature of the furnace front.

FIGURE P1-104

- 1-105** Solar radiation is incident on a  $5 \text{ m}^2$  solar absorber plate surface at a rate of  $800 \text{ W/m}^2$ . Ninety-three percent of the solar radiation is absorbed by the absorber plate, while the remaining 7 percent is reflected away. The solar absorber plate has a surface temperature of  $40^\circ\text{C}$  with an emissivity of  $0.9$  that experiences radiation exchange with the surrounding temperature of  $-5^\circ\text{C}$ . In addition, convective heat transfer occurs between the absorber plate surface and the ambient air of  $20^\circ\text{C}$  with a convection heat transfer coefficient of  $7 \text{ W/m}^2\cdot\text{K}$ . Determine the efficiency of the solar absorber, which is defined as the ratio of the usable heat collected by the absorber to the incident solar radiation on the absorber.

- 1-106** A flat-plate solar collector is used to heat water by having water flow through tubes attached at the back of the thin solar absorber plate. The absorber plate has a surface area of  $2 \text{ m}^2$  with emissivity and absorptivity of  $0.9$ . The surface temperature of the absorber is  $35^\circ\text{C}$ , and solar radiation is incident on the absorber at  $500 \text{ W/m}^2$  with a surrounding temperature of  $0^\circ\text{C}$ . Convection heat transfer coefficient at the absorber surface is  $5 \text{ W/m}^2\cdot\text{K}$ , while the ambient temperature is  $25^\circ\text{C}$ . Net heat rate absorbed by the solar collector heats the water from an inlet temperature ( $T_{\text{in}}$ ) to an outlet temperature ( $T_{\text{out}}$ ). If the water flow rate is  $5 \text{ g/s}$  with a specific heat of  $4.2 \text{ kJ/kg}\cdot\text{K}$ , determine the temperature rise of the water.

FIGURE P1-106

- 1-107**  Heat treatment of metals is commonly done using electrically heated draw batch furnaces. Consider a furnace that is situated in a room with surrounding air temperature of  $30^\circ\text{C}$  and an average convection heat transfer coefficient of  $15 \text{ W/m}^2\cdot\text{K}$ . The outer furnace front surface has an emissivity of  $0.7$ , and the inside surface is subjected to a heat flux of  $5 \text{ kW/m}^2$ . To ensure safety and avoid thermal burn of individuals working around the furnace, the outer front surface of the furnace should be kept below  $50^\circ\text{C}$ . Based on the information given about the furnace, does the furnace front surface require insulation to avoid thermal burn?

FIGURE P1-107

- 1-108**  The roof of a house consists of a  $22\text{-cm-thick}$  concrete slab ( $k = 2 \text{ W/m}\cdot\text{K}$ ) that is  $15 \text{ m}$  wide and  $20 \text{ m}$  long. The emissivity of the outer surface of the roof is  $0.9$ , and the convection heat transfer coefficient on that surface is estimated to be  $15 \text{ W/m}^2\cdot\text{K}$ . The inner surface of the roof is maintained at  $15^\circ\text{C}$ . On a clear winter night, the ambient air is reported to be at  $10^\circ\text{C}$  while the night sky temperature for radiation heat transfer is  $255 \text{ K}$ . Considering both radiation and convection heat transfer, determine the outer surface temperature and the rate of heat transfer through the roof.

If the house is heated by a furnace burning natural gas with an efficiency of 85 percent, and the unit cost of natural gas is  $\$1.20/\text{therm}$  ( $1 \text{ therm} = 105,500 \text{ kJ}$  of energy content), determine the money lost through the roof that night during a 14-hour period.

**1–109E** Consider a flat-plate solar collector placed horizontally on the flat roof of a house. The collector is 5 ft wide and 15 ft long, and the average temperature of the exposed surface of the collector is 100°F. The emissivity of the exposed surface of the collector is 0.9. Determine the rate of heat loss from the collector by convection and radiation during a calm day when the ambient air temperature is 70°F and the effective sky temperature for radiation exchange is 50°F. Take the convection heat transfer coefficient on the exposed surface to be 2.5 Btu/h·ft<sup>2</sup>·°F.

FIGURE P1–109E

**1–110** An AISI 304 stainless steel sheet is going through an annealing process inside an electrically heated oven. The ambient air inside the oven is 600°C, while the surrounding surfaces of the oven are at a uniform temperature of 750°C. If the emissivity of the stainless steel sheet is 0.40 and the average convection heat transfer coefficient is 10 W/m<sup>2</sup>·K, determine the temperature of the stainless steel sheet.

**1–111** Heat treatment is common in processing of semiconductor material. A 200-mm-diameter silicon wafer with thickness of 725 μm is being heat treated in a vacuum chamber by infrared heater. The surrounding walls of the chamber have a uniform temperature of 310 K. The infrared heater provides an incident radiation flux of 200 kW/m<sup>2</sup> on the upper surface of the wafer, and the emissivity and absorptivity of the wafer surface are 0.70. Using a pyrometer, the lower surface temperature of the wafer is measured to be 1000 K. Assuming there is no radiation exchange between the lower surface of the wafer and the surroundings, determine the upper surface temperature of the wafer. (Note: A pyrometer is a non-contacting device that intercepts and measures thermal radiation. This device can be used to determine the temperature of an object's surface.)

FIGURE P1–111

### Problem Solving Technique and EES

**1–112C** What is the value of the engineering software packages in (a) engineering education and (b) engineering practice?

**1–113** Determine a positive real root of this equation using EES:

$$3.5x^3 - 10x^{0.5} - 3x = -4$$

**1–114** Solve this system of two equations with two unknowns using EES:

$$\begin{aligned} x^3 - y^2 &= 10.5 \\ 3xy + y &= 4.6 \end{aligned}$$

**1–115** Solve this system of three equations with three unknowns using EES:

$$\begin{aligned} 2x - y + z &= 5 \\ 3x^2 + 2y &= z + 2 \\ xy + 2z &= 8 \end{aligned}$$

**1–116** Solve this system of three equations with three unknowns using EES:

$$\begin{aligned} x^2y - z &= 1.5 \\ x - 3y^{0.5} + xz &= -2 \\ x + y - z &= 4.2 \end{aligned}$$

**1–117** Using the parametric table and plot features of EES, determine the squares of the number from 1 to 100 in increments of 10 in tabular form, and plot the results.

### Special Topic: Thermal Comfort

**1–118C** What is metabolism? What is the range of metabolic rate for an average man? Why are we interested in the metabolic rate of the occupants of a building when we deal with heating and air conditioning?

**1–119C** Why is the metabolic rate of women, in general, lower than that of men? What is the effect of clothing on the environmental temperature that feels comfortable?

**1-120C** What is asymmetric thermal radiation? How does it cause thermal discomfort in the occupants of a room?

**1-121C** How do (a) draft and (b) cold floor surfaces cause discomfort for a room's occupants?

**1-122C** What is stratification? Is it likely to occur at places with low or high ceilings? How does it cause thermal discomfort for a room's occupants? How can stratification be prevented?

**1-123C** Why is it necessary to ventilate buildings? What is the effect of ventilation on energy consumption for heating in winter and for cooling in summer? Is it a good idea to keep the bathroom fans on all the time? Explain.

**1-124** Consider a house in Atlanta, Georgia, that is maintained at 22°C and has a total of 20 m<sup>2</sup> of window area. The windows are double-door type with wood frames and metal spacers and have a *U*-factor of 2.5 W/m<sup>2</sup>·K (see Prob. 1-125 for the definition of *U*-factor). The winter average temperature of Atlanta is 11.3°C. Determine the average rate of heat loss through the windows in winter.

**1-125** The rate of heat loss through a unit surface area of a window per unit temperature difference between the indoors and the outdoors is called the *U*-factor. The value of the *U*-factor ranges from about 1.25 W/m<sup>2</sup>·K (or 0.22 Btu/h·ft<sup>2</sup>·°F) for low-*e* coated, argon-filled, quadruple-pane windows to 6.25 W/m<sup>2</sup>·K (or 1.1 Btu/h·ft<sup>2</sup>·°F) for a single-pane window with aluminum frames. Determine the range for the rate of heat loss through a 1.2-m × 1.8-m window of a house that is maintained at 20°C when the outdoor air temperature is -8°C.

FIGURE P1-125

**1-126** Reconsider Prob. 1-125. Using EES (or other) software, plot the rate of heat loss through the window as a function of the *U*-factor. Discuss the results.

### Review Problems

**1-127** A 4-m × 5-m × 6-m room is to be heated by one ton (1000 kg) of liquid water contained in a tank placed in the room. The room is losing heat to the outside at an average rate of

10,000 kJ/h. The room is initially at 20°C and 100 kPa, and is maintained at an average temperature of 20°C at all times. If the hot water is to meet the heating requirements of this room for a 24-h period, determine the minimum temperature of the water when it is first brought into the room. Assume constant specific heats for both air and water at room temperature. *Answer: 77.4°C*

**1-128** Engine valves ( $c_p = 440 \text{ J/kg}\cdot\text{K}$  and  $\rho = 7840 \text{ kg/m}^3$ ) are to be heated from 40°C to 800°C in 5 min in the heat treatment section of a valve manufacturing facility. The valves have a cylindrical stem with a diameter of 8 mm and a length of 10 cm. The valve head and the stem may be assumed to be of equal surface area, with a total mass of 0.0788 kg. For a single valve, determine (a) the amount of heat transfer, (b) the average rate of heat transfer, (c) the average heat flux, and (d) the number of valves that can be heat treated per day if the heating section can hold 25 valves and it is used 10 h per day.

**1-129** A cylindrical resistor element on a circuit board dissipates 1.2 W of power. The resistor is 2 cm long, and has a diameter of 0.4 cm. Assuming heat to be transferred uniformly from all surfaces, determine (a) the amount of heat this resistor dissipates during a 24-hour period, (b) the heat flux, and (c) the fraction of heat dissipated from the top and bottom surfaces.

**1-130** The heat generated in the circuitry on the surface of a silicon chip ( $k = 130 \text{ W/m}\cdot\text{K}$ ) is conducted to the ceramic substrate to which it is attached. The chip is 6 mm × 6 mm in size and 0.5 mm thick and dissipates 5 W of power. Disregarding any heat transfer through the 0.5-mm high side surfaces, determine the temperature difference between the front and back surfaces of the chip in steady operation.

FIGURE P1-130

**1-131** A 0.3-cm-thick, 12-cm-high, and 18-cm-long circuit board houses 80 closely spaced logic chips on one side, each dissipating 0.06 W. The board is impregnated with copper fillings and has an effective thermal conductivity of 16 W/m·K. All the heat generated in the chips is conducted across the circuit board and is dissipated from the back side of the board to the ambient air. Determine the temperature difference between the two sides of the circuit board. *Answer: 0.042°C*

**1-132** A 40-cm-long, 800-W electric resistance heating element with diameter 0.5 cm and surface temperature 120°C is immersed in 75 kg of water initially at 20°C. Determine how long it will take for this heater to raise the water temperature to

80°C. Also, determine the convection heat transfer coefficients at the beginning and at the end of the heating process.

**1–133** It is well known that wind makes the cold air feel much colder as a result of the *wind chill effect* that is due to the increase in the convection heat transfer coefficient with increasing air velocity. The wind chill effect is usually expressed in terms of the *wind chill temperature* (WCT), which is the apparent temperature felt by exposed skin. For outdoor air temperature of 0°C, for example, the wind chill temperature is –5°C at 20 km/h winds and –9°C at 60 km/h winds. That is, a person exposed to 0°C windy air at 20 km/h will feel as cold as a person exposed to –5°C calm air (air motion under 5 km/h).

For heat transfer purposes, a standing man can be modeled as a 30-cm-diameter, 170-cm-long vertical cylinder with both the top and bottom surfaces insulated and with the side surface at an average temperature of 34°C. For a convection heat transfer coefficient of 15 W/m<sup>2</sup>·K, determine the rate of heat loss from this man by convection in still air at 20°C. What would your answer be if the convection heat transfer coefficient is increased to 30 W/m<sup>2</sup>·K as a result of winds? What is the wind chill temperature in this case?

*Answers:* 336 W, 672 W, 6°C

**1–134** An engine block with a surface area measured to be 0.95 m<sup>2</sup> generates a power output of 50 kW with a net engine efficiency of 35%. The engine block operates inside a compartment at 157°C and the average convection heat transfer coefficient is 50 W/m<sup>2</sup>·K. If convection is the only heat transfer mechanism occurring, determine the engine block surface temperature. *Answer:* 841°C

**1–135** Consider an electrical wire submerged in liquid water at atmospheric conditions. The wire has a diameter of 1 mm and a length of 15 cm. The current through the wire is increased until the water reaches a temperature of 100°C. For this situation (boiling water) use an average value of the upper and lower values of the convection heat transfer coefficients given in Table 1–5. The wire surface temperature is to be maintained at 115°C. How much electric power is required for this case?

**FIGURE P1–135**

**1–136** A cylindrical fuel rod of 2 cm in diameter is encased in a concentric tube and cooled by water. The fuel generates heat uniformly at a rate of 150 MW/m<sup>3</sup>. The convection heat transfer coefficient on the fuel rod is 5000 W/m<sup>2</sup>·K, and the average temperature of the cooling water, sufficiently far from the fuel rod, is 70°C. Determine the surface temperature of the fuel rod and discuss whether the value of the given convection heat transfer coefficient on the fuel rod is reasonable.

**FIGURE P1–136**

**1–137** The critical heat flux (CHF) is a thermal limit at which a boiling crisis occurs whereby an abrupt rise in temperature causes overheating on fuel rod surface that leads to damage. A cylindrical fuel rod of 2 cm in diameter is encased in a concentric tube and cooled by water. The fuel generates heat uniformly at a rate of 150 MW/m<sup>3</sup>. The average temperature of the cooling water, sufficiently far from the fuel rod, is 80°C. The operating pressure of the cooling water is such that the surface temperature of the fuel rod must be kept below 300°C to avoid the cooling water from reaching the critical heat flux. Determine the necessary convection heat transfer coefficient to avoid the critical heat flux from occurring.

**FIGURE P1–137**

**1–138** Consider a person standing in a room maintained at 20°C at all times. The inner surfaces of the walls, floors, and ceiling of the house are observed to be at an average temperature of 12°C in winter and 23°C in summer. Determine the rates of radiation heat transfer between this person and the surrounding surfaces in both summer and winter if the exposed surface area, emissivity, and the average outer surface temperature of the person are 1.6 m<sup>2</sup>, 0.95, and 32°C, respectively.

**1–139** Reconsider Prob. 1–138. Using EES (or other) software, plot the rate of radiation heat transfer in winter as a function of the temperature of the inner surface of the room in the range of 8°C to 18°C. Discuss the results.

**1–140** Consider a 3-m × 3-m × 3-m cubical furnace whose top and side surfaces closely approximate black surfaces at a temperature of 1200 K. The base surface has an emissivity of  $\varepsilon = 0.4$ , and is maintained at 800 K. Determine the net rate of radiation heat transfer to the base surface from the top and side surfaces. *Answer:* 340 kW

**1–141** A soldering iron has a cylindrical tip of 2.5 mm in diameter and 20 mm in length. With age and usage, the tip has oxidized and has an emissivity of 0.80. Assuming that the average convection heat transfer coefficient over the soldering iron

tip is  $25 \text{ W/m}^2\cdot\text{K}$ , and the surrounding air temperature is  $20^\circ\text{C}$ , determine the power required to maintain the tip at  $400^\circ\text{C}$ .

**FIGURE P1–141**

**1–142** A thin metal plate is insulated on the back and exposed to solar radiation on the front surface. The exposed surface of the plate has an absorptivity of 0.7 for solar radiation. If solar radiation is incident on the plate at a rate of  $550 \text{ W/m}^2$  and the surrounding air temperature is  $10^\circ\text{C}$ , determine the surface temperature of the plate when the heat loss by convection equals the solar energy absorbed by the plate. Take the convection heat transfer coefficient to be  $25 \text{ W/m}^2\cdot\text{K}$ , and disregard any heat loss by radiation.

**FIGURE P1–142**

**1–143** Consider a flat-plate solar collector placed on the roof of a house. The temperatures at the inner and outer surfaces of the glass cover are measured to be  $33^\circ\text{C}$  and  $31^\circ\text{C}$ , respectively. The glass cover has a surface area of  $2.5 \text{ m}^2$ , a thickness of  $0.6 \text{ cm}$ , and a thermal conductivity of  $0.7 \text{ W/m}\cdot\text{K}$ . Heat is lost from the outer surface of the cover by convection and radiation with a convection heat transfer coefficient of  $10 \text{ W/m}^2\cdot\text{K}$  and an ambient temperature of  $15^\circ\text{C}$ . Determine the fraction of heat lost from the glass cover by radiation.

**1–144** An electric heater with the total surface area of  $0.25 \text{ m}^2$  and emissivity 0.75 is in a room where the air has a temperature of  $20^\circ\text{C}$  and the walls are at  $10^\circ\text{C}$ . When the heater consumes  $500 \text{ W}$  of electric power, its surface has a steady temperature of  $120^\circ\text{C}$ . Determine the temperature of the heater surface when it consumes  $700 \text{ W}$ . Solve the problem (a) assuming negligible radiation and (b) taking radiation into consideration. Based on your results, comment on the assumption made in part (a).

**FIGURE P1–144**

**1–145** An ice skating rink is located in a building where the air is at  $T_{\text{air}} = 20^\circ\text{C}$  and the walls are at  $T_w = 25^\circ\text{C}$ . The convection heat transfer coefficient between the ice and the surrounding air is  $h = 10 \text{ W/m}^2\cdot\text{K}$ . The emissivity of ice is  $\varepsilon = 0.95$ . The latent heat of fusion of ice is  $h_{if} = 333.7 \text{ kJ/kg}$  and its density is  $920 \text{ kg/m}^3$ . (a) Calculate the refrigeration load of the system necessary to maintain the ice at  $T_s = 0^\circ\text{C}$  for an ice rink of  $12 \text{ m} \times 40 \text{ m}$ . (b) How long would it take to melt  $\delta = 3 \text{ mm}$  of ice from the surface of the rink if no cooling is supplied and the surface is considered insulated on the back side?

**FIGURE P1–145**

# Fundamentals of Engineering (FE) Exam Problems

- 1-146** A 2-kW electric resistance heater in a room is turned on and kept on for 50 minutes. The amount of energy transferred to the room by the heater is

- (a) 2 kJ                      (b) 100 kJ                      (c) 6000 kJ  
 (d) 7200 kJ                    (e) 12,000 kJ

- 1-147** A 2-kW electric resistance heater submerged in 30-kg water is turned on and kept on for 10 min. During the process, 500 kJ of heat is lost from the water. The temperature rise of water is

- (a) 5.6°C                    (b) 9.6°C                    (c) 13.6°C  
 (d) 23.3°C                (e) 42.5°C

- 1-148** Eggs with a mass of 0.15 kg per egg and a specific heat of 3.32 kJ/kg·°C are cooled from 32°C to 10°C at a rate of 200 eggs per minute. The rate of heat removal from the eggs is

- (a) 7.3 kW      (b) 53 kW      (c) 17 kW  
 (d) 438 kW      (e) 37 kW

- 1-149** A cold bottled drink ( $m = 2.5 \text{ kg}$ ,  $c_p = 4200 \text{ J/kg}\cdot\text{K}$ ) at  $5^\circ\text{C}$  is left on a table in a room. The average temperature of the drink is observed to rise to  $15^\circ\text{C}$  in 30 minutes. The average rate of heat transfer to the drink is

- 1-150** Water enters a pipe at 20°C at a rate of 0.50 kg/s and is heated to 60°C. The rate of heat transfer to the water is

- (a) 20 kW              (b) 42 kW              (c) 84 kW  
 (d) 126 kW            (e) 334 kW

- 1-151** Air enters a 12-m-long, 7-cm-diameter pipe at 50°C at a rate of 0.06 kg/s. The air is cooled at an average rate of 400 W per m<sup>2</sup> surface area of the pipe. The air temperature at the exit of the pipe is

- (a) 4.3°C                      (b) 17.5°C                      (c) 32.5°C  
 (d) 43.4°C                      (e) 45.8°C

- 1-152** Heat is lost steadily through a 0.5-cm thick  $2\text{ m} \times 3\text{ m}$  window glass whose thermal conductivity is  $0.7\text{ W/m}\cdot\text{K}$ . The inner and outer surface temperatures of the glass are measured to be  $12^\circ\text{C}$  to  $9^\circ\text{C}$ . The rate of heat loss by conduction through the glass is

- (a) 420 W                  (b) 5040 W                  (c) 17,600 W  
 (d) 1256 W                (e) 2520 W

- 1-153** Steady heat conduction occurs through a 0.3-m-thick  $9\text{ m} \times 3\text{ m}$  composite wall at a rate of 1.2 kW. If the inner and outer surface temperatures of the wall are  $15^\circ\text{C}$  and  $7^\circ\text{C}$ , the effective thermal conductivity of the wall is

- (a) 0.61 W/m·K      (b) 0.83 W/m·K      (c) 1.7 W/m·K  
 (d) 2.2 W/m·K      (e) 5.1 W/m·K

- 1-154** Heat is lost through a brick wall ( $k = 0.72 \text{ W/m}\cdot\text{K}$ ), which is 4 m long, 3 m wide, and 25 cm thick at a rate of 500 W. If the inner surface of the wall is at  $22^\circ\text{C}$ , the temperature at the midplane of the wall is

- (a)  $0^{\circ}\text{C}$       (b)  $7.5^{\circ}\text{C}$       (c)  $11.0^{\circ}\text{C}$   
 (d)  $14.8^{\circ}\text{C}$       (e)  $22^{\circ}\text{C}$

- 1-155** A 10-cm-high and 20-cm-wide circuit board houses on its surface 100 closely spaced chips, each generating heat at a rate of 0.12 W and transferring it by convection and radiation to the surrounding medium at 40°C. Heat transfer from the back surface of the board is negligible. If the combined convection and radiation heat transfer coefficient on the surface of the board is 22 W/m<sup>2</sup>·K, the average surface temperature of the chips is

- 1-156** A 40-cm-long, 0.4-cm-diameter electric resistance wire submerged in water is used to determine the convection heat transfer coefficient in water during boiling at 1 atm pressure. The surface temperature of the wire is measured to be 114°C when a wattmeter indicates the electric power consumption to be 7.6 kW. The heat transfer coefficient is

- (a) 108 kW/m<sup>2</sup>.K      (b) 13.3 kW/m<sup>2</sup>.K  
 (c) 68.1 kW/m<sup>2</sup>.K      (d) 0.76 kW/m<sup>2</sup>.K  
 (e) 256 kW/m<sup>2</sup>.K

- 1-157** While driving down a highway early in the evening, the air flow over an automobile establishes an overall heat transfer coefficient of  $18 \text{ W/m}^2\cdot\text{K}$ . The passenger cabin of this automobile exposes  $9 \text{ m}^2$  of surface to the moving ambient air. On a day when the ambient temperature is  $33^\circ\text{C}$ , how much cooling must the air conditioning system supply to maintain a temperature of  $20^\circ\text{C}$  in the passenger cabin?

- (a) 670 W                  (b) 1284 W                  (c) 2106 W  
 (d) 2565 W                  (e) 3210 W

- 1-158** Over 90 percent of the energy dissipated by an incandescent light bulb is in the form of heat, not light. What is the temperature of a vacuum-enclosed tungsten filament with an exposed surface area of  $2.03 \text{ cm}^2$  in a 100 W incandescent light bulb? The emissivity of tungsten at the anticipated high temperatures is about 0.35. Note that the light bulb consumes 100 W of electrical energy, and dissipates all of it by radiation.

- (a) 1870 K      (b) 2230 K      (c) 2640 K  
 (d) 3120 K      (e) 2980 K

- 1-159** On a still clear night, the sky appears to be a black-body with an equivalent temperature of 250 K. What is the air temperature when a strawberry field cools to 0°C and freezes if the heat transfer coefficient between the plants and air is 6 W/m<sup>2</sup>·K because of a light breeze and the plants have an emissivity of 0.9?

- (a)  $14^{\circ}\text{C}$  (b)  $7^{\circ}\text{C}$  (c)  $3^{\circ}\text{C}$  (d)  $0^{\circ}\text{C}$  (e)  $-3^{\circ}\text{C}$

**1-160** A 25-cm-diameter black ball at 130°C is suspended in air, and is losing heat to the surrounding air at 25°C by convection with a heat transfer coefficient of 12 W/m<sup>2</sup>·K, and by radiation to the surrounding surfaces at 15°C. The total rate of heat transfer from the black ball is

- (a) 217 W      (b) 247 W      (c) 251 W  
 (d) 465 W      (e) 2365 W

**1-161** A 3-m<sup>2</sup> black surface at 140°C is losing heat to the surrounding air at 35°C by convection with a heat transfer coefficient of 16 W/m<sup>2</sup>·K, and by radiation to the surrounding surfaces at 15°C. The total rate of heat loss from the surface is

- (a) 5105 W      (b) 2940 W      (c) 3779 W  
 (d) 8819 W      (e) 5040 W

**1-162** A person's head can be approximated as a 25-cm diameter sphere at 35°C with an emissivity of 0.95. Heat is lost from the head to the surrounding air at 25°C by convection with a heat transfer coefficient of 11 W/m<sup>2</sup>·K, and by radiation to the surrounding surfaces at 10°C. Disregarding the neck, determine the total rate of heat loss from the head.

- (a) 22 W      (b) 27 W      (c) 49 W  
 (d) 172 W      (e) 249 W

**1-163** A room is heated by a 1.2 kW electric resistance heater whose wires have a diameter of 4 mm and a total length of 3.4 m. The air in the room is at 23°C and the interior surfaces of the room are at 17°C. The convection heat transfer coefficient on the surface of the wires is 8 W/m<sup>2</sup>·K. If the rates of heat transfer from the wires to the room by convection and by radiation are equal, the surface temperature of the wire is

- (a) 3534°C      (b) 1778°C      (c) 1772°C  
 (d) 98°C      (e) 25°C

**1-164** A person standing in a room loses heat to the air in the room by convection and to the surrounding surfaces by radiation. Both the air in the room and the surrounding surfaces are at 20°C. The exposed surface of the person is 1.5 m<sup>2</sup> and has an average temperature of 32°C, and an emissivity of 0.90. If the rates of heat transfer from the person by convection and by radiation are equal, the combined heat transfer coefficient is

- (a) 0.008 W/m<sup>2</sup>·K      (b) 3.0 W/m<sup>2</sup>·K  
 (c) 5.5 W/m<sup>2</sup>·K      (d) 8.3 W/m<sup>2</sup>·K  
 (e) 10.9 W/m<sup>2</sup>·K

### Design and Essay Problems

**1-165** Write an essay on how microwave ovens work, and explain how they cook much faster than conventional ovens. Discuss whether conventional electric or microwave ovens consume more electricity for the same task.

**1-166** Using information from the utility bills for the coldest month last year, estimate the average rate of heat loss from your house for that month. In your analysis, consider the contribution of the internal heat sources such as people, lights, and appliances. Identify the primary sources of heat loss from your house and propose ways of improving the energy efficiency of your house.

**1-167** Conduct this experiment to determine the combined heat transfer coefficient between an incandescent lightbulb and the surrounding air and surfaces using a 60-W lightbulb. You will need a thermometer, which can be purchased in a hardware store, and a metal glue. You will also need a piece of string and a ruler to calculate the surface area of the lightbulb. First, measure the air temperature in the room, and then glue the tip of the thermocouple wire of the thermometer to the glass of the lightbulb. Turn the light on and wait until the temperature reading stabilizes. The temperature reading will give the surface temperature of the lightbulb. Assuming 10 percent of the rated power of the bulb is converted to light and is transmitted by the glass, calculate the heat transfer coefficient from Newton's law of cooling.

**1-168** It is well-known that at the same outdoor air temperature a person is cooled at a faster rate under windy conditions than under calm conditions due to the higher convection heat transfer coefficients associated with windy air. The phrase *wind chill* is used to relate the rate of heat loss from people under windy conditions to an equivalent air temperature for calm conditions (considered to be a wind or walking speed of 3 mph or 5 km/h). The hypothetical *wind chill temperature* (WCT), called the *wind chill temperature index* (WCTI), is an equivalent air temperature equal to the air temperature needed to produce the same cooling effect under calm conditions. A 2003 report on wind chill temperature by the U.S. National Weather Service gives the WCTI in metric units as

$$\text{WCTI } (\text{°C}) = 13.12 + 0.6215T - 11.37V^{0.16} + 0.3965TV^{0.16}$$

where  $T$  is the air temperature in °C and  $V$  the wind speed in km/h at 10 m elevation. Show that this relation can be expressed in English units as

$$\text{WCTI } (\text{°F}) = 35.74 + 0.6215T - 35.75V^{0.16} + 0.4275TV^{0.16}$$

where  $T$  is the air temperature in °F and  $V$  the wind speed in mph at 33 ft elevation. Also, prepare a table for WCTI for air temperatures ranging from 10 to -60°C and wind speeds ranging from 10 to 80 km/h. Comment on the magnitude of the cooling effect of the wind and the danger of frostbite.

# HEAT CONDUCTION EQUATION

**H**eat transfer has *direction* as well as *magnitude*. The rate of heat conduction in a specified direction is proportional to the *temperature gradient*, which is the rate of change in temperature with distance in that direction. Heat conduction in a medium, in general, is three-dimensional and time dependent, and the temperature in a medium varies with position as well as time, that is,  $T = T(x, y, z, t)$ . Heat conduction in a medium is said to be *steady* when the temperature does not vary with time, and *unsteady* or *transient* when it does. Heat conduction in a medium is said to be *one-dimensional* when conduction is significant in one dimension only and negligible in the other two primary dimensions, *two-dimensional* when conduction in the third dimension is negligible, and *three-dimensional* when conduction in all dimensions is significant.

We start this chapter with a description of steady, unsteady, and multi-dimensional heat conduction. Then we derive the differential equation that governs heat conduction in a large plane wall, a long cylinder, and a sphere, and generalize the results to three-dimensional cases in rectangular, cylindrical, and spherical coordinates. Following a discussion of the boundary conditions, we present the formulation of heat conduction problems and their solutions. Finally, we consider heat conduction problems with variable thermal conductivity.

This chapter deals with the theoretical and mathematical aspects of heat conduction, and it can be covered selectively, if desired, without causing a significant loss in continuity. The more practical aspects of heat conduction are covered in the following two chapters.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Understand multidimensionality and time dependence of heat transfer, and the conditions under which a heat transfer problem can be approximated as being one-dimensional,
- Obtain the differential equation of heat conduction in various co-ordinate systems, and simplify it for steady one-dimensional case,
- Identify the thermal conditions on surfaces, and express them mathematically as boundary and initial conditions,
- Solve one-dimensional heat conduction problems and obtain the temperature distributions within a medium and the heat flux,
- Analyze one-dimensional heat conduction in solids that involve heat generation, and
- Evaluate heat conduction in solids with temperature-dependent thermal conductivity.

**FIGURE 2-1**

Heat transfer has direction as well as magnitude, and thus it is a *vector* quantity.

**FIGURE 2-2**

Indicating direction for heat transfer (positive in the positive direction; negative in the negative direction).

## 2-1 ■ INTRODUCTION

In Chapter 1 heat conduction was defined as the transfer of thermal energy from the more energetic particles of a medium to the adjacent less energetic ones. It was stated that conduction can take place in liquids and gases as well as solids provided that there is no bulk motion involved.

Although heat transfer and temperature are closely related, they are of a different nature. Unlike temperature, heat transfer has direction as well as magnitude, and thus it is a *vector* quantity (Fig. 2-1). Therefore, we must specify both direction and magnitude in order to describe heat transfer completely at a point. For example, saying that the temperature on the inner surface of a wall is 18°C describes the temperature at that location fully. But saying that the heat flux on that surface is 50 W/m<sup>2</sup> immediately prompts the question “in what direction?” We can answer this question by saying that heat conduction is toward the inside (indicating heat gain) or toward the outside (indicating heat loss).

To avoid such questions, we can work with a coordinate system and indicate direction with plus or minus signs. The generally accepted convention is that heat transfer in the positive direction of a coordinate axis is positive and in the opposite direction it is negative. Therefore, a positive quantity indicates heat transfer in the positive direction and a negative quantity indicates heat transfer in the negative direction (Fig. 2-2).

The driving force for any form of heat transfer is the *temperature difference*, and the larger the temperature difference, the larger the rate of heat transfer. Some heat transfer problems in engineering require the determination of the *temperature distribution* (the variation of temperature) throughout the medium in order to calculate some quantities of interest such as the local heat transfer rate, thermal expansion, and thermal stress at some critical locations at specified times. The specification of the temperature at a point in a medium first requires the specification of the location of that point. This can be done by choosing a suitable coordinate system such as the *rectangular*, *cylindrical*, or *spherical* coordinates, depending on the geometry involved, and a convenient reference point (the origin).

The *location* of a point is specified as  $(x, y, z)$  in rectangular coordinates, as  $(r, \phi, z)$  in cylindrical coordinates, and as  $(r, \phi, \theta)$  in spherical coordinates, where the distances  $x$ ,  $y$ ,  $z$ , and  $r$  and the angles  $\phi$  and  $\theta$  are as shown in Fig. 2-3. Then the temperature at a point  $(x, y, z)$  at time  $t$  in rectangular coordinates is expressed as  $T(x, y, z, t)$ . The best coordinate system for a given geometry is the one that describes the surfaces of the geometry best. For example, a parallelepiped is best described in rectangular coordinates since each surface can be described by a constant value of the  $x$ -,  $y$ -, or  $z$ -coordinates. A cylinder is best suited for cylindrical coordinates since its lateral surface can be described by a constant value of the radius. Similarly, the entire outer surface of a spherical body can best be described by a constant value of the radius in spherical coordinates. For an arbitrarily shaped body, we normally use rectangular coordinates since it is easier to deal with distances than with angles.

The notation just described is also used to identify the variables involved in a heat transfer problem. For example, the notation  $T(x, y, z, t)$  implies that the temperature varies with the space variables  $x$ ,  $y$ , and  $z$  as well as time.

**FIGURE 2-3**

The various distances and angles involved when describing the location of a point in different coordinate systems.

The notation  $T(x)$ , on the other hand, indicates that the temperature varies in the  $x$ -direction only and there is no variation with the other two space coordinates or time.

## Steady versus Transient Heat Transfer

Heat transfer problems are often classified as being **steady** (also called *steady-state*) or **transient** (also called *unsteady*). The term *steady* implies *no change* with time at any point within the medium, while *transient* implies *variation with time* or *time dependence*. Therefore, the temperature or heat flux remains unchanged with time during steady heat transfer through a medium at any location, although both quantities may vary from one location to another (Fig. 2-4). For example, heat transfer through the walls of a house is steady when the conditions inside the house and the outdoors remain constant for several hours. But even in this case, the temperatures on the inner and outer surfaces of the wall will be different unless the temperatures inside and outside the house are the same. The cooling of an apple in a refrigerator, on the other hand, is a transient heat transfer process since the temperature at any fixed point within the apple will change with time during cooling. During transient heat transfer, the temperature normally varies with time as well as position. In the special case of variation with time but not with position, the temperature of the medium changes *uniformly* with time. Such heat transfer systems are called **lumped systems**. A small metal object such as a thermocouple junction or a thin copper wire, for example, can be analyzed as a lumped system during a heating or cooling process.

Most heat transfer problems encountered in practice are *transient* in nature, but they are usually analyzed under some presumed *steady* conditions since steady processes are easier to analyze, and they provide the answers to our questions. For example, heat transfer through the walls and ceiling of a typical house is never steady since the outdoor conditions such as the temperature, the speed and direction of the wind, the location of the sun, and so on, change constantly. The conditions in a typical house are not so steady either. Therefore, it is almost impossible to perform a heat transfer analysis of a house accurately. But then, do we really need an in-depth heat transfer analysis?

**FIGURE 2-4**

Transient and steady heat conduction in a plane wall.

If the purpose of a heat transfer analysis of a house is to determine the proper size of a heater, which is usually the case, we need to know the *maximum* rate of heat loss from the house, which is determined by considering the heat loss from the house under *worst* conditions for an extended period of time, that is, during *steady* operation under worst conditions. Therefore, we can get the answer to our question by doing a heat transfer analysis under steady conditions. If the heater is large enough to keep the house warm under most demanding conditions, it is large enough for all conditions. The approach described above is a common practice in engineering.

## Multidimensional Heat Transfer

Heat transfer problems are also classified as being *one-dimensional*, *two-dimensional*, or *three-dimensional*, depending on the relative magnitudes of heat transfer rates in different directions and the level of accuracy desired. In the most general case, heat transfer through a medium is **three-dimensional**. That is, the temperature varies along all three primary directions within the medium during the heat transfer process. The temperature distribution throughout the medium at a specified time as well as the heat transfer rate at any location in this general case can be described by a set of three coordinates such as the  $x$ ,  $y$ , and  $z$  in the rectangular (or Cartesian) coordinate system; the  $r$ ,  $\phi$ , and  $z$  in the cylindrical coordinate system; and the  $r$ ,  $\phi$ , and  $\theta$  in the spherical (or polar) coordinate system. The temperature distribution in this case is expressed as  $T(x, y, z, t)$ ,  $T(r, \phi, z, t)$ , and  $T(r, \phi, \theta, t)$  in the respective coordinate systems.

The temperature in a medium, in some cases, varies mainly in two primary directions, and the variation of temperature in the third direction (and thus heat transfer in that direction) is negligible. A heat transfer problem in that case is said to be **two-dimensional**. For example, the steady temperature distribution in a long bar of rectangular cross section can be expressed as  $T(x, y)$  if the temperature variation in the  $z$ -direction (along the bar) is negligible and there is no change with time (Fig. 2–5).

A heat transfer problem is said to be **one-dimensional** if the temperature in the medium varies in one direction only and thus heat is transferred in one direction, and the variation of temperature and thus heat transfer in other directions are negligible or zero. For example, heat transfer through the glass of a window can be considered to be one-dimensional since heat transfer through the glass occurs predominantly in one direction (the direction normal to the surface of the glass) and heat transfer in other directions (from one side edge to the other and from the top edge to the bottom) is negligible (Fig. 2–6). Likewise, heat transfer through a hot water pipe can be considered to be one-dimensional since heat transfer through the pipe occurs predominantly in the radial direction from the hot water to the ambient, and heat transfer along the pipe and along the circumference of a cross section ( $z$ - and  $\phi$ -directions) is typically negligible. Heat transfer to an egg dropped into boiling water is also nearly one-dimensional because of symmetry. Heat is transferred to the egg in this case in the radial direction, that is, along straight lines passing through the midpoint of the egg.

We mentioned in Chapter 1 that the rate of heat conduction through a medium in a specified direction (say, in the  $x$ -direction) is proportional to the temperature difference across the medium and the area normal to the direction

**FIGURE 2–5**

Two-dimensional heat transfer in a long rectangular bar.

**FIGURE 2–6**

Heat transfer through the window of a house can be taken to be one-dimensional.

of heat transfer, but is inversely proportional to the distance in that direction. This was expressed in the differential form by **Fourier's law of heat conduction** for one-dimensional heat conduction as

$$\dot{Q}_{\text{cond}} = -kA \frac{dT}{dx} \quad (\text{W}) \quad (2-1)$$

where  $k$  is the *thermal conductivity* of the material, which is a measure of the ability of a material to conduct heat, and  $dT/dx$  is the *temperature gradient*, which is the slope of the temperature curve on a  $T$ - $x$  diagram (Fig. 2–7). The thermal conductivity of a material, in general, varies with temperature. But sufficiently accurate results can be obtained by using a constant value for thermal conductivity at the *average* temperature.

Heat is conducted in the direction of decreasing temperature, and thus the temperature gradient is negative when heat is conducted in the positive  $x$ -direction. The *negative sign* in Eq. 2–1 ensures that heat transfer in the positive  $x$ -direction is a positive quantity.

To obtain a general relation for Fourier's law of heat conduction, consider a medium in which the temperature distribution is three-dimensional. Fig. 2–8 shows an isothermal surface in that medium. The heat transfer vector at a point  $P$  on this surface must be perpendicular to the surface, and it must point in the direction of decreasing temperature. If  $n$  is the normal of the isothermal surface at point  $P$ , the rate of heat conduction at that point can be expressed by Fourier's law as

$$\dot{Q}_n = -kA \frac{\partial T}{\partial n} \quad (\text{W}) \quad (2-2)$$

In rectangular coordinates, the heat conduction vector can be expressed in terms of its components as

$$\vec{Q}_n = \dot{Q}_x \vec{i} + \dot{Q}_y \vec{j} + \dot{Q}_z \vec{k} \quad (2-3)$$

where  $\vec{i}$ ,  $\vec{j}$ , and  $\vec{k}$  are the unit vectors, and  $\dot{Q}_x$ ,  $\dot{Q}_y$ , and  $\dot{Q}_z$  are the magnitudes of the heat transfer rates in the  $x$ -,  $y$ -, and  $z$ -directions, which again can be determined from Fourier's law as

$$\dot{Q}_x = -kA_x \frac{\partial T}{\partial x}, \quad \dot{Q}_y = -kA_y \frac{\partial T}{\partial y}, \quad \text{and} \quad \dot{Q}_z = -kA_z \frac{\partial T}{\partial z} \quad (2-4)$$

Here  $A_x$ ,  $A_y$  and  $A_z$  are heat conduction areas normal to the  $x$ -,  $y$ -, and  $z$ -directions, respectively (Fig. 2–8).

Most engineering materials are *isotropic* in nature, and thus they have the same properties in all directions. For such materials we do not need to be concerned about the variation of properties with direction. But in *anisotropic* materials such as the fibrous or composite materials, the properties may change with direction. For example, some of the properties of wood along the grain are different than those in the direction normal to the grain. In such cases the thermal conductivity may need to be expressed as a tensor quantity to account for the variation with direction. The treatment of such advanced topics is beyond the scope of this text, and we will assume the thermal conductivity of a material to be independent of direction.

**FIGURE 2-7**

The temperature gradient  $dT/dx$  is simply the slope of the temperature curve on a  $T$ - $x$  diagram.

**FIGURE 2-8**

The heat transfer vector is always normal to an isothermal surface and can be resolved into its components like any other vector.

**FIGURE 2-9**

Heat is generated in the heating coils of an electric range as a result of the conversion of electrical energy to heat.

## Heat Generation

A medium through which heat is conducted may involve the conversion of mechanical, electrical, nuclear, or chemical energy into heat (or thermal energy). In heat conduction analysis, such conversion processes are characterized as **heat** (or **thermal energy**) **generation**.

For example, the temperature of a resistance wire rises rapidly when electric current passes through it as a result of the electrical energy being converted to heat at a rate of  $I^2R$ , where  $I$  is the current and  $R$  is the electrical resistance of the wire (Fig. 2-9). The safe and effective removal of this heat away from the sites of heat generation (the electronic circuits) is the subject of *electronics cooling*, which is one of the modern application areas of heat transfer.

Likewise, a large amount of heat is generated in the fuel elements of nuclear reactors as a result of nuclear fission that serves as the *heat source* for the nuclear power plants. The natural disintegration of radioactive elements in nuclear waste or other radioactive material also results in the generation of heat throughout the body. The heat generated in the sun as a result of the fusion of hydrogen into helium makes the sun a large nuclear reactor that supplies heat to the earth.

Another source of heat generation in a medium is exothermic chemical reactions that may occur throughout the medium. The chemical reaction in this case serves as a *heat source* for the medium. In the case of endothermic reactions, however, heat is absorbed instead of being released during reaction, and thus the chemical reaction serves as a *heat sink*. The heat generation term becomes a negative quantity in this case.

Often it is also convenient to model the absorption of radiation such as solar energy or gamma rays as heat generation when these rays penetrate deep into the body while being absorbed gradually. For example, the absorption of solar energy in large bodies of water can be treated as heat generation throughout the water at a rate equal to the rate of absorption, which varies with depth (Fig. 2-10). But the absorption of solar energy by an opaque body occurs within a few microns of the surface, and the solar energy that penetrates into the medium in this case can be treated as specified heat flux on the surface.

Note that heat generation is a *volumetric phenomenon*. That is, it occurs throughout the body of a medium. Therefore, the rate of heat generation in a medium is usually specified *per unit volume* and is denoted by  $\dot{e}_{\text{gen}}$ , whose unit is  $\text{W/m}^3$  or  $\text{Btu/h}\cdot\text{ft}^3$ .

The rate of heat generation in a medium may vary with time as well as position within the medium. When the variation of heat generation with position is known, the *total* rate of heat generation in a medium of volume  $V$  can be determined from

$$\dot{E}_{\text{gen}} = \int_V \dot{e}_{\text{gen}} dV \quad (\text{W}) \quad (2-5)$$

In the special case of *uniform* heat generation, as in the case of electric resistance heating throughout a homogeneous material, the relation in Eq. 2-5 reduces to  $\dot{E}_{\text{gen}} = \dot{e}_{\text{gen}} V$ , where  $\dot{e}_{\text{gen}}$  is the constant rate of heat generation per unit volume.

**FIGURE 2-10**

The absorption of solar radiation by water can be treated as heat generation.

**EXAMPLE 2–1 Heat Generation in a Hair Dryer**

The resistance wire of a 1200-W hair dryer is 80 cm long and has a diameter of  $D = 0.3$  cm (Fig. 2–11). Determine the rate of heat generation in the wire per unit volume, in  $\text{W}/\text{cm}^3$ , and the heat flux on the outer surface of the wire as a result of this heat generation.

**SOLUTION** The power consumed by the resistance wire of a hair dryer is given. The heat generation and the heat flux are to be determined.

**Assumptions** Heat is generated uniformly in the resistance wire.

**Analysis** A 1200-W hair dryer converts electrical energy into heat in the wire at a rate of 1200 W. Therefore, the rate of heat generation in a resistance wire is equal to the power consumption of a resistance heater. Then the rate of heat generation in the wire per unit volume is determined by dividing the total rate of heat generation by the volume of the wire,

$$\dot{e}_{\text{gen}} = \frac{\dot{E}_{\text{gen}}}{V_{\text{wire}}} = \frac{\dot{E}_{\text{gen}}}{(\pi D^2/4)L} = \frac{1200 \text{ W}}{[\pi(0.3 \text{ cm})^2/4](80 \text{ cm})} = 212 \text{ W/cm}^3$$

Similarly, heat flux on the outer surface of the wire as a result of this heat generation is determined by dividing the total rate of heat generation by the surface area of the wire,

$$\dot{Q}_s = \frac{\dot{E}_{\text{gen}}}{A_{\text{wire}}} = \frac{\dot{E}_{\text{gen}}}{\pi D L} = \frac{1200 \text{ W}}{\pi(0.3 \text{ cm})(80 \text{ cm})} = 15.9 \text{ W/cm}^2$$

**Discussion** Note that heat generation is expressed per unit volume in  $\text{W}/\text{cm}^3$  or  $\text{Btu}/\text{h}\cdot\text{ft}^3$ , whereas heat flux is expressed per unit surface area in  $\text{W}/\text{cm}^2$  or  $\text{Btu}/\text{h}\cdot\text{ft}^2$ .

**FIGURE 2–11**

Schematic for Example 2–1.

## 2–2 ▪ ONE-DIMENSIONAL HEAT CONDUCTION EQUATION

Consider heat conduction through a large plane wall such as the wall of a house, the glass of a single pane window, the metal plate at the bottom of a pressing iron, a cast-iron steam pipe, a cylindrical nuclear fuel element, an electrical resistance wire, the wall of a spherical container, or a spherical metal ball that is being quenched or tempered. Heat conduction in these and many other geometries can be approximated as being *one-dimensional* since heat conduction through these geometries is dominant in one direction and negligible in other directions. Next we develop the one-dimensional heat conduction equation in rectangular, cylindrical, and spherical coordinates.

### Heat Conduction Equation in a Large Plane Wall

Consider a thin element of thickness  $\Delta x$  in a large plane wall, as shown in Fig. 2–12. Assume the density of the wall is  $\rho$ , the specific heat is  $c$ , and the area of the wall normal to the direction of heat transfer is  $A$ . An *energy balance* on this thin element during a small time interval  $\Delta t$  can be expressed as

**FIGURE 2–12**

One-dimensional heat conduction through a volume element in a large plane wall.

$$\left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction} \\ \text{at } x \end{array} \right) - \left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction} \\ \text{at } x + \Delta x \end{array} \right) + \left( \begin{array}{c} \text{Rate of heat} \\ \text{generation} \\ \text{inside the} \\ \text{element} \end{array} \right) = \left( \begin{array}{c} \text{Rate of change} \\ \text{of the energy} \\ \text{content of the} \\ \text{element} \end{array} \right)$$

or

$$\dot{Q}_x - \dot{Q}_{x+\Delta x} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} \quad (2-6)$$

But the change in the energy content of the element and the rate of heat generation within the element can be expressed as

$$\Delta E_{\text{element}} = E_{t+\Delta t} - E_t = mc(T_{t+\Delta t} - T_t) = \rho c A \Delta x (T_{t+\Delta t} - T_t) \quad (2-7)$$

$$\dot{E}_{\text{gen, element}} = \dot{e}_{\text{gen}} V_{\text{element}} = \dot{e}_{\text{gen}} A \Delta x \quad (2-8)$$

Substituting into Eq. 2-6, we get

$$\dot{Q}_x - \dot{Q}_{x+\Delta x} + \dot{e}_{\text{gen}} A \Delta x = \rho c A \Delta x \frac{T_{t+\Delta t} - T_t}{\Delta t} \quad (2-9)$$

Dividing by  $A \Delta x$  gives

$$-\frac{1}{A} \frac{\dot{Q}_{x+\Delta x} - \dot{Q}_x}{\Delta x} + \dot{e}_{\text{gen}} = \rho c \frac{T_{t+\Delta t} - T_t}{\Delta t} \quad (2-10)$$

Taking the limit as  $\Delta x \rightarrow 0$  and  $\Delta t \rightarrow 0$  yields

$$\frac{1}{A} \frac{\partial}{\partial x} \left( k A \frac{\partial T}{\partial x} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-11)$$

since, from the definition of the derivative and Fourier's law of heat conduction,

$$\lim_{\Delta x \rightarrow 0} \frac{\dot{Q}_{x+\Delta x} - \dot{Q}_x}{\Delta x} = \frac{\partial \dot{Q}}{\partial x} = \frac{\partial}{\partial x} \left( -k A \frac{\partial T}{\partial x} \right) \quad (2-12)$$

Noting that the area  $A$  is constant for a plane wall, the one-dimensional transient heat conduction equation in a plane wall becomes

$$\text{Variable conductivity: } \frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-13)$$

The thermal conductivity  $k$  of a material, in general, depends on the temperature  $T$  (and therefore  $x$ ), and thus it cannot be taken out of the derivative. However, the *thermal conductivity* in most practical applications can be assumed to remain *constant* at some average value. The equation above in that case reduces to

$$\text{Constant conductivity: } \frac{\partial^2 T}{\partial x^2} + \frac{\dot{e}_{\text{gen}}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-14)$$

where the property  $\alpha = k/\rho c$  is the **thermal diffusivity** of the material and represents how fast heat propagates through a material. It reduces to the following forms under specified conditions (Fig. 2-13):

**FIGURE 2-13**

The simplification of the one-dimensional heat conduction equation in a plane wall for the case of constant conductivity for steady conduction with no heat generation.

$$(1) \text{ Steady-state: } (\partial/\partial t = 0) \quad \frac{d^2T}{dx^2} + \frac{\dot{e}_{\text{gen}}}{k} = 0 \quad (2-15)$$

$$(2) \text{ Transient, no heat generation: } (\dot{e}_{\text{gen}} = 0) \quad \frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-16)$$

$$(3) \text{ Steady-state, no heat generation: } (\partial/\partial t = 0 \text{ and } \dot{e}_{\text{gen}} = 0) \quad \frac{d^2T}{dx^2} = 0 \quad (2-17)$$

Note that we replaced the partial derivatives by ordinary derivatives in the one-dimensional steady heat conduction case since the partial and ordinary derivatives of a function are identical when the function depends on a single variable only [ $T = T(x)$  in this case]. For the general solution of Eqs. 2-15 and 2-17 refer to the TOPIC OF SPECIAL INTEREST (A Brief Review of Differential Equations) at the end of this chapter.

## Heat Conduction Equation in a Long Cylinder

Now consider a thin cylindrical shell element of thickness  $\Delta r$  in a long cylinder, as shown in Fig. 2-14. Assume the density of the cylinder is  $\rho$ , the specific heat is  $c$ , and the length is  $L$ . The area of the cylinder normal to the direction of heat transfer at any location is  $A = 2\pi rL$  where  $r$  is the value of the radius at that location. Note that the heat transfer area  $A$  depends on  $r$  in this case, and thus it varies with location. An *energy balance* on this thin cylindrical shell element during a small time interval  $\Delta t$  can be expressed as

$$\left( \begin{array}{l} \text{Rate of heat} \\ \text{conduction} \\ \text{at } r \end{array} \right) - \left( \begin{array}{l} \text{Rate of heat} \\ \text{conduction} \\ \text{at } r + \Delta r \end{array} \right) + \left( \begin{array}{l} \text{Rate of heat} \\ \text{generation} \\ \text{inside the} \\ \text{element} \end{array} \right) = \left( \begin{array}{l} \text{Rate of change} \\ \text{of the energy} \\ \text{content of the} \\ \text{element} \end{array} \right)$$

or

$$\dot{Q}_r - \dot{Q}_{r+\Delta r} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} \quad (2-18)$$

The change in the energy content of the element and the rate of heat generation within the element can be expressed as

$$\Delta E_{\text{element}} = E_{t+\Delta t} - E_t = mc(T_{t+\Delta t} - T_t) = \rho c A \Delta r (T_{t+\Delta t} - T_t) \quad (2-19)$$

$$\dot{E}_{\text{gen, element}} = \dot{e}_{\text{gen}} V_{\text{element}} = \dot{e}_{\text{gen}} A \Delta r \quad (2-20)$$

Substituting into Eq. 2-18, we get

$$\dot{Q}_r - \dot{Q}_{r+\Delta r} + \dot{e}_{\text{gen}} A \Delta r = \rho c A \Delta r \frac{T_{t+\Delta t} - T_t}{\Delta t} \quad (2-21)$$

where  $A = 2\pi rL$ . You may be tempted to express the area at the *middle* of the element using the *average* radius as  $A = 2\pi(r + \Delta r/2)L$ . But there is nothing we can gain from this complication since later in the analysis we will take the limit as  $\Delta r \rightarrow 0$  and thus the term  $\Delta r/2$  will drop out. Now dividing the equation above by  $A \Delta r$  gives

$$-\frac{1}{A} \frac{\dot{Q}_{r+\Delta r} - \dot{Q}_r}{\Delta r} + \dot{e}_{\text{gen}} = \rho c \frac{T_{t+\Delta t} - T_t}{\Delta t} \quad (2-22)$$

**FIGURE 2-14**  
One-dimensional heat conduction through a volume element in a long cylinder.

**FIGURE 2-15**

Two equivalent forms of the differential equation for the one-dimensional steady heat conduction in a cylinder with no heat generation.

Taking the limit as  $\Delta r \rightarrow 0$  and  $\Delta t \rightarrow 0$  yields

$$\frac{1}{A} \frac{\partial}{\partial r} \left( kA \frac{\partial T}{\partial r} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-23)$$

since, from the definition of the derivative and Fourier's law of heat conduction,

$$\lim_{\Delta r \rightarrow 0} \frac{\dot{Q}_{r+\Delta r} - \dot{Q}_r}{\Delta r} = \frac{\partial \dot{Q}}{\partial r} = \frac{\partial}{\partial r} \left( -kA \frac{\partial T}{\partial r} \right) \quad (2-24)$$

Noting that the heat transfer area in this case is  $A = 2\pi rL$ , the one-dimensional transient heat conduction equation in a cylinder becomes

$$\text{Variable conductivity: } \frac{1}{r} \frac{\partial}{\partial r} \left( rk \frac{\partial T}{\partial r} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-25)$$

For the case of constant thermal conductivity, the previous equation reduces to

$$\text{Constant conductivity: } \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + \frac{\dot{e}_{\text{gen}}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-26)$$

where again the property  $\alpha = k/\rho c$  is the thermal diffusivity of the material. Eq. 2-26 reduces to the following forms under specified conditions (Fig. 2-15):

$$(1) \text{ Steady-state: } (\partial/\partial t = 0) \quad \frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{e}_{\text{gen}}}{k} = 0 \quad (2-27)$$

$$(2) \text{ Transient, no heat generation: } (\dot{e}_{\text{gen}} = 0) \quad \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-28)$$

$$(3) \text{ Steady-state, no heat generation: } (\partial/\partial t = 0 \text{ and } \dot{e}_{\text{gen}} = 0) \quad \frac{d}{dr} \left( r \frac{dT}{dr} \right) = 0 \quad (2-29)$$

Note that we again replaced the partial derivatives by ordinary derivatives in the one-dimensional steady heat conduction case since the partial and ordinary derivatives of a function are identical when the function depends on a single variable only [ $T = T(r)$  in this case]. For the general solution of Eqs. 2-27 and 2-29 refer to the TOPIC OF SPECIAL INTEREST (A Brief Review of Differential Equations) at the end of this chapter.

## Heat Conduction Equation in a Sphere

Now consider a sphere with density  $\rho$ , specific heat  $c$ , and outer radius  $R$ . The area of the sphere normal to the direction of heat transfer at any location is  $A = 4\pi r^2$ , where  $r$  is the value of the radius at that location. Note that the heat transfer area  $A$  depends on  $r$  in this case also, and thus it varies with location. By considering a thin spherical shell element of thickness  $\Delta r$  and repeating the approach described above for the cylinder by using  $A = 4\pi r^2$  instead of  $A = 2\pi rL$ , the one-dimensional transient heat conduction equation for a sphere is determined to be (Fig. 2-16)

$$\text{Variable conductivity: } \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 k \frac{\partial T}{\partial r} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-30)$$

which, in the case of constant thermal conductivity, reduces to

$$\text{Constant conductivity: } \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) + \frac{\dot{e}_{\text{gen}}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-31)$$

**FIGURE 2-16**

One-dimensional heat conduction through a volume element in a sphere.

where again the property  $\alpha = k/\rho c$  is the thermal diffusivity of the material. It reduces to the following forms under specified conditions:

$$(1) \text{ Steady-state: } \frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) + \frac{\dot{e}_{\text{gen}}}{k} = 0 \quad (2-32)$$

$$(2) \text{ Transient, no heat generation: } \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-33)$$

$$(3) \text{ Steady-state, no heat generation: } \frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = 0 \quad \text{or} \quad r \frac{d^2 T}{dr^2} + 2 \frac{dT}{dr} = 0 \quad (2-34)$$

where again we replaced the partial derivatives by ordinary derivatives in the one-dimensional steady heat conduction case. For the general solution of Eqs. 2-32 and 2-34 refer to the TOPIC OF SPECIAL INTEREST (A Brief Review of Differential Equations) at the end of this chapter.

## Combined One-Dimensional Heat Conduction Equation

An examination of the one-dimensional transient heat conduction equations for the plane wall, cylinder, and sphere reveals that all three equations can be expressed in a compact form as

$$\frac{1}{r^n} \frac{\partial}{\partial r} \left( r^n k \frac{\partial T}{\partial r} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-35)$$

where  $n = 0$  for a plane wall,  $n = 1$  for a cylinder, and  $n = 2$  for a sphere. In the case of a plane wall, it is customary to replace the variable  $r$  by  $x$ . This equation can be simplified for steady-state or no heat generation cases as described before.

### EXAMPLE 2-2 Heat Conduction through the Bottom of a Pan

Consider a steel pan placed on top of an electric range to cook spaghetti (Fig. 2-17). The bottom section of the pan is 0.4 cm thick and has a diameter of 18 cm. The electric heating unit on the range top consumes 800 W of power during cooking, and 80 percent of the heat generated in the heating element is transferred uniformly to the pan. Assuming constant thermal conductivity, obtain the differential equation that describes the variation of the temperature in the bottom section of the pan during steady operation.

**SOLUTION** A steel pan placed on top of an electric range is considered. The differential equation for the variation of temperature in the bottom of the pan is to be obtained.

**Analysis** The bottom section of the pan has a large surface area relative to its thickness and can be approximated as a large plane wall. Heat flux is applied to the bottom surface of the pan uniformly, and the conditions on the inner surface are also uniform. Therefore, we expect the heat transfer through the bottom section of the pan to be from the bottom surface toward the top, and heat transfer in this case can reasonably be approximated as being one-dimensional. Taking the direction normal to the bottom surface of the pan to be the  $x$ -axis, we will have  $T = T(x)$  during steady operation since the temperature in this case will depend on  $x$  only.

**FIGURE 2-17**  
Schematic for Example 2-2.

The thermal conductivity is given to be constant, and there is no heat generation in the medium (within the bottom section of the pan). Therefore, the differential equation governing the variation of temperature in the bottom section of the pan in this case is simply Eq. 2-17,

$$\frac{d^2T}{dx^2} = 0$$

which is the steady one-dimensional heat conduction equation in rectangular coordinates under the conditions of constant thermal conductivity and no heat generation.

**Discussion** Note that the conditions at the surface of the medium have no effect on the differential equation.

**FIGURE 2-18**

Schematic for Example 2-3.

### EXAMPLE 2-3 Heat Conduction in a Resistance Heater

A 2-kW resistance heater wire with thermal conductivity  $k = 15 \text{ W/m}\cdot\text{K}$ , diameter  $D = 0.4 \text{ cm}$ , and length  $L = 50 \text{ cm}$  is used to boil water by immersing it in water (Fig. 2-18). Assuming the variation of the thermal conductivity of the wire with temperature to be negligible, obtain the differential equation that describes the variation of the temperature in the wire during steady operation.

**SOLUTION** The resistance wire of a water heater is considered. The differential equation for the variation of temperature in the wire is to be obtained.

**Analysis** The resistance wire can be considered to be a very long cylinder since its length is more than 100 times its diameter. Also, heat is generated uniformly in the wire and the conditions on the outer surface of the wire are uniform. Therefore, it is reasonable to expect the temperature in the wire to vary in the radial  $r$  direction only and thus the heat transfer to be one-dimensional. Then we have  $T = T(r)$  during steady operation since the temperature in this case depends on  $r$  only.

The rate of heat generation in the wire per unit volume can be determined from

$$\dot{e}_{\text{gen}} = \frac{\dot{E}_{\text{gen}}}{V_{\text{wire}}} = \frac{\dot{E}_{\text{gen}}}{(\pi D^2/4)L} = \frac{2000 \text{ W}}{[\pi(0.004 \text{ m})^2/4](0.5 \text{ m})} = 0.318 \times 10^9 \text{ W/m}^3$$

Noting that the thermal conductivity is given to be constant, the differential equation that governs the variation of temperature in the wire is simply Eq. 2-27,

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{e}_{\text{gen}}}{k} = 0$$

which is the steady one-dimensional heat conduction equation in cylindrical coordinates for the case of constant thermal conductivity.

**Discussion** Note again that the conditions at the surface of the wire have no effect on the differential equation.

**EXAMPLE 2–4** Cooling of a Hot Metal Ball in Air

A spherical metal ball of radius  $R$  is heated in an oven to a temperature of  $600^{\circ}\text{F}$  throughout and is then taken out of the oven and allowed to cool in ambient air at  $T_{\infty} = 75^{\circ}\text{F}$  by convection and radiation (Fig. 2–19). The thermal conductivity of the ball material is known to vary linearly with temperature. Assuming the ball is cooled uniformly from the entire outer surface, obtain the differential equation that describes the variation of the temperature in the ball during cooling.

**SOLUTION** A hot metal ball is allowed to cool in ambient air. The differential equation for the variation of temperature within the ball is to be obtained.

**Analysis** The ball is initially at a uniform temperature and is cooled uniformly from the entire outer surface. Also, the temperature at any point in the ball changes with time during cooling. Therefore, this is a one-dimensional transient heat conduction problem since the temperature within the ball changes with the radial distance  $r$  and the time  $t$ . That is,  $T = T(r, t)$ .

The thermal conductivity is given to be variable, and there is no heat generation in the ball. Therefore, the differential equation that governs the variation of temperature in the ball in this case is obtained from Eq. 2–30 by setting the heat generation term equal to zero. We obtain

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 k \frac{\partial T}{\partial r} \right) = \rho c \frac{\partial T}{\partial t}$$

which is the one-dimensional transient heat conduction equation in spherical coordinates under the conditions of variable thermal conductivity and no heat generation.

**Discussion** Note again that the conditions at the outer surface of the ball have no effect on the differential equation.

**FIGURE 2–19**

Schematic for Example 2–4.

## 2–3 • GENERAL HEAT CONDUCTION EQUATION

In the last section we considered one-dimensional heat conduction and assumed heat conduction in other directions to be negligible. Most heat transfer problems encountered in practice can be approximated as being one-dimensional, and we mostly deal with such problems in this text. However, this is not always the case, and sometimes we need to consider heat transfer in other directions as well. In such cases heat conduction is said to be *multidimensional*, and in this section we develop the governing differential equation in such systems in rectangular, cylindrical, and spherical coordinate systems.

### Rectangular Coordinates

Consider a small rectangular element of length  $\Delta x$ , width  $\Delta y$ , and height  $\Delta z$ , as shown in Fig. 2–20. Assume the density of the body is  $\rho$  and the specific heat is  $c$ . An *energy balance* on this element during a small time interval  $\Delta t$  can be expressed as

$$\left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction at} \\ x, y, \text{ and } z \end{array} \right) - \left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction} \\ \text{at } x + \Delta x \\ y + \Delta y \text{ and } z + \Delta z \end{array} \right) + \left( \begin{array}{c} \text{Rate of heat} \\ \text{generation} \\ \text{inside the} \\ \text{element} \end{array} \right) = \left( \begin{array}{c} \text{Rate of change} \\ \text{of the energy} \\ \text{content of the} \\ \text{element} \end{array} \right)$$

**FIGURE 2–20**

Three-dimensional heat conduction through a rectangular volume element.

or

$$\dot{Q}_x + \dot{Q}_y + \dot{Q}_z - \dot{Q}_{x+\Delta x} - \dot{Q}_{y+\Delta y} - \dot{Q}_{z+\Delta z} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} \quad (2-36)$$

Noting that the volume of the element is  $V_{\text{element}} = \Delta x \Delta y \Delta z$ , the change in the energy content of the element and the rate of heat generation within the element can be expressed as

$$\begin{aligned}\Delta E_{\text{element}} &= E_{t+\Delta t} - E_t = mc(T_{t+\Delta t} - T_t) = \rho c \Delta x \Delta y \Delta z (T_{t+\Delta t} - T_t) \\ \dot{E}_{\text{gen, element}} &= \dot{e}_{\text{gen}} V_{\text{element}} = \dot{e}_{\text{gen}} \Delta x \Delta y \Delta z\end{aligned}$$

Substituting into Eq. 2-36, we get

$$\dot{Q}_x + \dot{Q}_y + \dot{Q}_z - \dot{Q}_{x+\Delta x} - \dot{Q}_{y+\Delta y} - \dot{Q}_{z+\Delta z} + \dot{e}_{\text{gen}} \Delta x \Delta y \Delta z = \rho c \Delta x \Delta y \Delta z \frac{T_{t+\Delta t} - T_t}{\Delta t}$$

Dividing by  $\Delta x \Delta y \Delta z$  gives

$$-\frac{1}{\Delta y \Delta z} \frac{\dot{Q}_{x+\Delta x} - \dot{Q}_x}{\Delta x} - \frac{1}{\Delta x \Delta z} \frac{\dot{Q}_{y+\Delta y} - \dot{Q}_y}{\Delta y} - \frac{1}{\Delta x \Delta y} \frac{\dot{Q}_{z+\Delta z} - \dot{Q}_z}{\Delta z} + \dot{e}_{\text{gen}} = \rho c \frac{T_{t+\Delta t} - T_t}{\Delta t} \quad (2-37)$$

Noting that the heat transfer areas of the element for heat conduction in the  $x$ ,  $y$ , and  $z$  directions are  $A_x = \Delta y \Delta z$ ,  $A_y = \Delta x \Delta z$ , and  $A_z = \Delta x \Delta y$ , respectively, and taking the limit as  $\Delta x$ ,  $\Delta y$ ,  $\Delta z$  and  $\Delta t \rightarrow 0$  yields

$$\frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-38)$$

since, from the definition of the derivative and Fourier's law of heat conduction,

$$\begin{aligned}\lim_{\Delta x \rightarrow 0} \frac{1}{\Delta y \Delta z} \frac{\dot{Q}_{x+\Delta x} - \dot{Q}_x}{\Delta x} &= \frac{1}{\Delta y \Delta z} \frac{\partial Q_x}{\partial x} = \frac{1}{\Delta y \Delta z} \frac{\partial}{\partial x} \left( -k \Delta y \Delta z \frac{\partial T}{\partial x} \right) = -\frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) \\ \lim_{\Delta y \rightarrow 0} \frac{1}{\Delta x \Delta z} \frac{\dot{Q}_{y+\Delta y} - \dot{Q}_y}{\Delta y} &= \frac{1}{\Delta x \Delta z} \frac{\partial Q_y}{\partial y} = \frac{1}{\Delta x \Delta z} \frac{\partial}{\partial y} \left( -k \Delta x \Delta z \frac{\partial T}{\partial y} \right) = -\frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) \\ \lim_{\Delta z \rightarrow 0} \frac{1}{\Delta x \Delta y} \frac{\dot{Q}_{z+\Delta z} - \dot{Q}_z}{\Delta z} &= \frac{1}{\Delta x \Delta y} \frac{\partial Q_z}{\partial z} = \frac{1}{\Delta x \Delta y} \frac{\partial}{\partial z} \left( -k \Delta x \Delta y \frac{\partial T}{\partial z} \right) = -\frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right)\end{aligned}$$

Eq. 2-38 is the general heat conduction equation in rectangular coordinates. In the case of constant thermal conductivity, it reduces to

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} + \frac{\dot{e}_{\text{gen}}}{k} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-39)$$

where the property  $\alpha = k/\rho c$  is again the *thermal diffusivity* of the material. Eq. 2-39 is known as the **Fourier-Biot equation**, and it reduces to these forms under specified conditions:

(1) *Steady-state:*  
(called the **Poisson equation**)

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} + \frac{\dot{e}_{\text{gen}}}{k} = 0 \quad (2-40)$$

(2) *Transient, no heat generation:*  
(called the **diffusion equation**)

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (2-41)$$

(3) *Steady-state, no heat generation:*  
(called the **Laplace equation**)

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} = 0 \quad (2-42)$$

Note that in the special case of one-dimensional heat transfer in the  $x$ -direction, the derivatives with respect to  $y$  and  $z$  drop out and the equations above reduce to the ones developed in the previous section for a plane wall (Fig. 2–21).

FIGURE 2-21

The three-dimensional heat conduction equations reduce to the one-dimensional ones when the temperature varies in one dimension only.

FIGURE 2-22

A differential volume element in cylindrical coordinates.

FIGURE 2-23

A differential volume element in spherical coordinates.

## Spherical Coordinates

The general heat conduction equations in spherical coordinates can be obtained from an energy balance on a volume element in spherical coordinates, shown in Fig. 2–23, by following the steps outlined above. It can also be obtained directly from Eq. 2–38 by coordinate transformation using the following relations between the coordinates of a point in rectangular and spherical coordinate systems:

$$x = r \cos \phi \sin \theta, \quad y = r \sin \phi \sin \theta, \quad \text{and} \quad z = r \cos \theta$$

Again after lengthy manipulations, we obtain

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( kr^2 \frac{\partial T}{\partial r} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{\partial}{\partial \phi} \left( k \frac{\partial T}{\partial \phi} \right) + \frac{1}{r^2 \sin \theta} \frac{\partial}{\partial \theta} \left( k \sin \theta \frac{\partial T}{\partial \theta} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t} \quad (2-44)$$

Obtaining analytical solutions to these differential equations requires a knowledge of the solution techniques of partial differential equations, which is beyond the scope of this introductory text. Here we limit our consideration to one-dimensional steady-state cases, since they result in ordinary differential equations.

**FIGURE 2-24**

Schematic for Example 2-5.

**EXAMPLE 2-5 Heat Conduction in a Short Cylinder**

A short cylindrical metal billet of radius  $R$  and height  $h$  is heated in an oven to a temperature of  $600^{\circ}\text{F}$  throughout and is then taken out of the oven and allowed to cool in ambient air at  $T_{\infty} = 65^{\circ}\text{F}$  by convection and radiation. Assuming the billet is cooled uniformly from all outer surfaces and the variation of the thermal conductivity of the material with temperature is negligible, obtain the differential equation that describes the variation of the temperature in the billet during this cooling process.

**SOLUTION** A short cylindrical billet is cooled in ambient air. The differential equation for the variation of temperature is to be obtained.

**Analysis** The billet shown in Fig. 2-24 is initially at a uniform temperature and is cooled uniformly from the top and bottom surfaces in the  $z$ -direction as well as the lateral surface in the radial  $r$ -direction. Also, the temperature at any point in the ball changes with time during cooling. Therefore, this is a two-dimensional transient heat conduction problem since the temperature within the billet changes with the radial and axial distances  $r$  and  $z$  and with time  $t$ . That is,  $T = T(r, z, t)$ .

The thermal conductivity is given to be constant, and there is no heat generation in the billet. Therefore, the differential equation that governs the variation of temperature in the billet in this case is obtained from Eq. 2-43 by setting the heat generation term and the derivatives with respect to  $\phi$  equal to zero. We obtain

$$\frac{1}{r} \frac{\partial}{\partial r} \left( kr \frac{\partial T}{\partial r} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) = \rho c \frac{\partial T}{\partial t}$$

In the case of constant thermal conductivity, it reduces to

$$\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + \frac{\partial^2 T}{\partial z^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

which is the desired equation.

**Discussion** Note that the boundary and initial conditions have no effect on the differential equation.

## 2-4 • BOUNDARY AND INITIAL CONDITIONS

The heat conduction equations above were developed using an energy balance on a differential element inside the medium, and they remain the same regardless of the *thermal conditions* on the *surfaces* of the medium. That is, the differential equations do not incorporate any information related to the conditions on the surfaces such as the surface temperature or a specified heat flux. Yet we know that the heat flux and the temperature distribution in a medium depend on the conditions at the surfaces, and the description of a heat transfer problem in a medium is not complete without a full description of the thermal conditions at the bounding surfaces of the medium. The *mathematical expressions* of the thermal conditions at the boundaries are called the **boundary conditions**.

From a mathematical point of view, solving a differential equation is essentially a process of *removing derivatives*, or an *integration* process, and thus the solution of a differential equation typically involves arbitrary constants (Fig. 2–25). It follows that to obtain a unique solution to a problem, we need to specify more than just the governing differential equation. We need to specify some conditions (such as the value of the function or its derivatives at some value of the independent variable) so that forcing the solution to satisfy these conditions at specified points will result in unique values for the arbitrary constants and thus a *unique solution*. But since the differential equation has no place for the additional information or conditions, we need to supply them separately in the form of boundary or initial conditions.

Consider the variation of temperature along the wall of a brick house in winter. The temperature at any point in the wall depends on, among other things, the conditions at the two surfaces of the wall such as the air temperature of the house, the velocity and direction of the winds, and the solar energy incident on the outer surface. That is, the temperature distribution in a medium depends on the conditions at the boundaries of the medium as well as the heat transfer mechanism inside the medium. To describe a heat transfer problem completely, *two boundary conditions* must be given for *each direction* of the coordinate system along which heat transfer is significant (Fig. 2–26). Therefore, we need to specify *two boundary conditions* for one-dimensional problems, *four boundary conditions* for two-dimensional problems, and *six boundary conditions* for three-dimensional problems. In the case of the wall of a house, for example, we need to specify the conditions at two locations (the inner and the outer surfaces) of the wall since heat transfer in this case is one-dimensional. But in the case of a parallelepiped, we need to specify six boundary conditions (one at each face) when heat transfer in all three dimensions is significant.

The physical argument presented above is consistent with the mathematical nature of the problem since the heat conduction equation is second order (i.e., involves second derivatives with respect to the space variables) in all directions along which heat conduction is significant, and the general solution of a second-order linear differential equation involves two arbitrary constants for each direction. That is, the number of boundary conditions that needs to be specified in a direction is equal to the order of the differential equation in that direction.

Reconsider the brick wall already discussed. The temperature at any point on the wall at a specified time also depends on the condition of the wall at the beginning of the heat conduction process. Such a condition, which is usually specified at time  $t = 0$ , is called the **initial condition**, which is a mathematical expression for the temperature distribution of the medium initially. Note that we need only one initial condition for a heat conduction problem regardless of the dimension since the conduction equation is first order in time (it involves the first derivative of temperature with respect to time).

In rectangular coordinates, the initial condition can be specified in the general form as

$$T(x, y, z, 0) = f(x, y, z) \quad (2-45)$$

where the function  $f(x, y, z)$  represents the temperature distribution throughout the medium at time  $t = 0$ . When the medium is initially at a uniform

FIGURE 2–25

The general solution of a typical differential equation involves arbitrary constants, and thus an infinite number of solutions.

FIGURE 2–26

To describe a heat transfer problem completely, two boundary conditions must be given for each direction along which heat transfer is significant.

temperature of  $T_i$ , the initial condition in Eq. 2–45 can be expressed as  $T(x, y, z, 0) = T_i$ . Note that under *steady* conditions, the heat conduction equation does not involve any time derivatives, and thus we do not need to specify an initial condition.

The heat conduction equation is first order in time, and thus the initial condition cannot involve any derivatives (it is limited to a specified temperature). However, the heat conduction equation is second order in space coordinates, and thus a boundary condition may involve first derivatives at the boundaries as well as specified values of temperature. Boundary conditions most commonly encountered in practice are the *specified temperature*, *specified heat flux*, *convection*, and *radiation* boundary conditions.

## 1 Specified Temperature Boundary Condition

The *temperature* of an exposed surface can usually be measured directly and easily. Therefore, one of the easiest ways to specify the thermal conditions on a surface is to specify the temperature. For one-dimensional heat transfer through a plane wall of thickness  $L$ , for example, the specified temperature boundary conditions can be expressed as (Fig. 2–27)

$$\begin{aligned} T(0, t) &= T_1 \\ T(L, t) &= T_2 \end{aligned} \quad (2-46)$$

where  $T_1$  and  $T_2$  are the specified temperatures at surfaces at  $x = 0$  and  $x = L$ , respectively. The specified temperatures can be constant, which is the case for steady heat conduction, or may vary with time.

## 2 Specified Heat Flux Boundary Condition

When there is sufficient information about energy interactions at a surface, it may be possible to determine the rate of heat transfer and thus the *heat flux*  $\dot{q}$  (heat transfer rate per unit surface area,  $\text{W/m}^2$ ) on that surface, and this information can be used as one of the boundary conditions. The heat flux in the positive  $x$ -direction anywhere in the medium, including the boundaries, can be expressed by *Fourier's law* of heat conduction as

$$\dot{q} = -k \frac{\partial T}{\partial x} = \left( \begin{array}{l} \text{Heat flux in the} \\ \text{positive } x-\text{direction} \end{array} \right) \quad (\text{W/m}^2) \quad (2-47)$$

Then the boundary condition at a boundary is obtained by setting the specified heat flux equal to  $-k(\partial T/\partial x)$  at that boundary. The sign of the specified heat flux is determined by inspection: *positive* if the heat flux is in the positive direction of the coordinate axis, and *negative* if it is in the opposite direction. Note that it is extremely important to have the *correct sign* for the specified heat flux since the wrong sign will invert the direction of heat transfer and cause the heat gain to be interpreted as heat loss (Fig. 2–28).

For a plate of thickness  $L$  subjected to heat flux of  $50 \text{ W/m}^2$  into the medium from both sides, for example, the specified heat flux boundary conditions can be expressed as

$$-k \frac{\partial T(0, t)}{\partial x} = 50 \quad \text{and} \quad -k \frac{\partial T(L, t)}{\partial x} = -50 \quad (2-48)$$

**FIGURE 2–27**  
Specified temperature boundary conditions on both surfaces of a plane wall.

**FIGURE 2–28**  
Specified heat flux boundary conditions on both surfaces of a plane wall.

Note that the heat flux at the surface at  $x = L$  is in the *negative x*-direction, and thus it is  $-50 \text{ W/m}^2$ . The direction of heat flux arrows at  $x = L$  in Fig. 2-28 in this case would be reversed.

## Special Case: Insulated Boundary

Some surfaces are commonly insulated in practice in order to minimize heat loss (or heat gain) through them. Insulation reduces heat transfer but does not totally eliminate it unless its thickness is infinity. However, heat transfer through a properly insulated surface can be taken to be zero since adequate insulation reduces heat transfer through a surface to negligible levels. Therefore, a well-insulated surface can be modeled as a surface with a specified heat flux of zero. Then the boundary condition on a perfectly insulated surface (at  $x = 0$ , for example) can be expressed as (Fig. 2-29)

$$k \frac{\partial T(0, t)}{\partial x} = 0 \quad \text{or} \quad \frac{\partial T(0, t)}{\partial x} = 0 \quad (2-49)$$

That is, *on an insulated surface, the first derivative of temperature with respect to the space variable (the temperature gradient) in the direction normal to the insulated surface is zero*. This also means that the temperature function must be perpendicular to an insulated surface since the slope of temperature at the surface must be zero.

**FIGURE 2-29**

A plane wall with insulation and specified temperature boundary conditions.

## Another Special Case: Thermal Symmetry

Some heat transfer problems possess *thermal symmetry* as a result of the symmetry in imposed thermal conditions. For example, the two surfaces of a large hot plate of thickness  $L$  suspended vertically in air is subjected to the same thermal conditions, and thus the temperature distribution in one half of the plate is the same as that in the other half. That is, the heat transfer problem in this plate possesses thermal symmetry about the center plane at  $x = L/2$ . Also, the direction of heat flow at any point in the plate is toward the surface closer to the point, and there is no heat flow across the center plane. Therefore, the center plane can be viewed as an insulated surface, and the thermal condition at this plane of symmetry can be expressed as (Fig. 2-30)

$$\frac{\partial T(L/2, t)}{\partial x} = 0 \quad (2-50)$$

which resembles the *insulation or zero heat flux* boundary condition. This result can also be deduced from a plot of temperature distribution with a maximum, and thus zero slope, at the center plane.

In the case of cylindrical (or spherical) bodies having thermal symmetry about the center line (or midpoint), the thermal symmetry boundary condition requires that the first derivative of temperature with respect to  $r$  (the radial variable) be zero at the centerline (or the midpoint).

**FIGURE 2-30**

Thermal symmetry boundary condition at the center plane of a plane wall.

**FIGURE 2–31**

Schematic for Example 2–6.

**EXAMPLE 2–6 Heat Flux Boundary Condition**

Consider an aluminum pan used to cook beef stew on top of an electric range. The bottom section of the pan is  $L = 0.3$  cm thick and has a diameter of  $D = 20$  cm. The electric heating unit on the range top consumes 800 W of power during cooking, and 90 percent of the heat generated in the heating element is transferred to the pan. During steady operation, the temperature of the inner surface of the pan is measured to be 110°C. Express the boundary conditions for the bottom section of the pan during this cooking process.

**SOLUTION** An aluminum pan on an electric range top is considered. The boundary conditions for the bottom of the pan are to be obtained.

**Analysis** The heat transfer through the bottom section of the pan is from the bottom surface toward the top and can reasonably be approximated as being one-dimensional. We take the direction normal to the bottom surfaces of the pan as the  $x$  axis with the origin at the outer surface, as shown in Fig. 2–31. Then the inner and outer surfaces of the bottom section of the pan can be represented by  $x = 0$  and  $x = L$ , respectively. During steady operation, the temperature will depend on  $x$  only and thus  $T = T(x)$ .

The boundary condition on the outer surface of the bottom of the pan at  $x = 0$  can be approximated as being specified heat flux since it is stated that 90 percent of the 800 W (i.e., 720 W) is transferred to the pan at that surface. Therefore,

$$-k \frac{dT(0)}{dx} = \dot{q}_0$$

where

$$\dot{q}_0 = \frac{\text{Heat transfer rate}}{\text{Bottom surface area}} = \frac{0.720 \text{ kW}}{\pi(0.1 \text{ m})^2} = 22.9 \text{ kW/m}^2$$

The temperature at the inner surface of the bottom of the pan is specified to be 110°C. Then the boundary condition on this surface can be expressed as

$$T(L) = 110^\circ\text{C}$$

where  $L = 0.003$  m.

**Discussion** Note that the determination of the boundary conditions may require some reasoning and approximations.

**3 Convection Boundary Condition**

Convection is probably the most common boundary condition encountered in practice since most heat transfer surfaces are exposed to an environment at a specified temperature. The convection boundary condition is based on a *surface energy balance* expressed as

$$\left( \begin{array}{l} \text{Heat conduction} \\ \text{at the surface in a} \\ \text{selected direction} \end{array} \right) = \left( \begin{array}{l} \text{Heat convection} \\ \text{at the surface in} \\ \text{the same direction} \end{array} \right)$$

For one-dimensional heat transfer in the  $x$ -direction in a plate of thickness  $L$ , the convection boundary conditions on both surfaces can be expressed as

$$-k \frac{\partial T(0, t)}{\partial x} = h_1 [T_{\infty 1} - T(0, t)] \quad (2-51a)$$

and

$$-k \frac{\partial T(L, t)}{\partial x} = h_2 [T(L, t) - T_{\infty 2}] \quad (2-51b)$$

where  $h_1$  and  $h_2$  are the convection heat transfer coefficients and  $T_{\infty 1}$  and  $T_{\infty 2}$  are the temperatures of the surrounding mediums on the two sides of the plate, as shown in Fig. 2-32.

In writing Eqs. 2-51 for convection boundary conditions, we have selected the direction of heat transfer to be the positive  $x$ -direction at both surfaces. But those expressions are equally applicable when heat transfer is in the opposite direction at one or both surfaces since reversing the direction of heat transfer at a surface simply reverses the signs of *both* conduction and convection terms at that surface. This is equivalent to multiplying an equation by  $-1$ , which has no effect on the equality (Fig. 2-33). Being able to select either direction as the direction of heat transfer is certainly a relief since often we do not know the surface temperature and thus the direction of heat transfer at a surface in advance. This argument is also valid for other boundary conditions such as the radiation and combined boundary conditions discussed shortly.

Note that a surface has zero thickness and thus no mass, and it cannot store any energy. Therefore, the entire net heat entering the surface from one side must leave the surface from the other side. The convection boundary condition simply states that heat continues to flow from a body to the surrounding medium at the same rate, and it just changes vehicles at the surface from conduction to convection (or vice versa in the other direction). This is analogous to people traveling on buses on land and transferring to the ships at the shore. If the passengers are not allowed to wander around at the shore, then the rate at which the people are unloaded at the shore from the buses must equal the rate at which they board the ships. We may call this the conservation of “people” principle.

Also note that the surface temperatures  $T(0, t)$  and  $T(L, t)$  are not known (if they were known, we would simply use them as the specified temperature boundary condition and not bother with convection). But a surface temperature can be determined once the solution  $T(x, t)$  is obtained by substituting the value of  $x$  at that surface into the solution.

### EXAMPLE 2-7 Convection and Insulation Boundary Conditions

Steam flows through a pipe shown in Fig. 2-34 at an average temperature of  $T_{\infty} = 200^{\circ}\text{C}$ . The inner and outer radii of the pipe are  $r_1 = 8 \text{ cm}$  and  $r_2 = 8.5 \text{ cm}$ , respectively, and the outer surface of the pipe is heavily insulated. If the convection heat transfer coefficient on the inner surface of the pipe is  $h = 65 \text{ W/m}^2\cdot\text{K}$ , express the boundary conditions on the inner and outer surfaces of the pipe during transient periods.

**FIGURE 2-32**

Convection boundary conditions on the two surfaces of a plane wall.

**FIGURE 2-33**

The assumed direction of heat transfer at a boundary has no effect on the boundary condition expression.

FIGURE 2-34

Schematic for Example 2-7.

**SOLUTION** The flow of steam through an insulated pipe is considered. The boundary conditions on the inner and outer surfaces of the pipe are to be obtained.

**Analysis** During initial transient periods, heat transfer through the pipe material predominantly is in the radial direction, and thus can be approximated as being one-dimensional. Then the temperature within the pipe material changes with the radial distance  $r$  and the time  $t$ . That is,  $T = T(r, t)$ .

It is stated that heat transfer between the steam and the pipe at the inner surface is by convection. Then taking the direction of heat transfer to be the positive  $r$  direction, the boundary condition on that surface can be expressed as

$$-k \frac{\partial T(r_1, t)}{\partial r} = h[T_\infty - T(r_1)]$$

The pipe is said to be well insulated on the outside, and thus heat loss through the outer surface of the pipe can be assumed to be negligible. Then the boundary condition at the outer surface can be expressed as

$$\frac{\partial T(r_2, t)}{\partial r} = 0$$

**Discussion** Note that the temperature gradient must be zero on the outer surface of the pipe at all times.

## 4 Radiation Boundary Condition

In some cases, such as those encountered in space and cryogenic applications, a heat transfer surface is surrounded by an evacuated space and thus there is no convection heat transfer between a surface and the surrounding medium. In such cases, *radiation* becomes the only mechanism of heat transfer between the surface under consideration and the surroundings. Using an energy balance, the radiation boundary condition on a surface can be expressed as

$$\left( \begin{array}{l} \text{Heat conduction} \\ \text{at the surface in a} \\ \text{selected direction} \end{array} \right) = \left( \begin{array}{l} \text{Radiation exchange} \\ \text{at the surface in} \\ \text{the same direction} \end{array} \right)$$

For one-dimensional heat transfer in the  $x$ -direction in a plate of thickness  $L$ , the radiation boundary conditions on both surfaces can be expressed as (Fig. 2-35)

$$-k \frac{\partial T(0, t)}{\partial x} = \varepsilon_1 \sigma [T_{\text{surr}, 1}^4 - T(0, t)^4] \quad (2-52a)$$

and

$$-k \frac{\partial T(L, t)}{\partial x} = \varepsilon_2 \sigma [T(L, t)^4 - T_{\text{surr}, 2}^4] \quad (2-52b)$$

where  $\varepsilon_1$  and  $\varepsilon_2$  are the emissivities of the boundary surfaces,  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4$  is the Stefan–Boltzmann constant, and  $T_{\text{surr}, 1}$  and  $T_{\text{surr}, 2}$  are the average temperatures of the surfaces surrounding the two sides of the plate, respectively. Note that the temperatures in radiation calculations must be expressed in K or R (not in °C or °F).

The radiation boundary condition involves the fourth power of temperature, and thus it is a *nonlinear* condition. As a result, the application of this boundary condition results in powers of the unknown coefficients, which makes it difficult

FIGURE 2-35

Radiation boundary conditions on both surfaces of a plane wall.

to determine them. Therefore, it is tempting to ignore radiation exchange at a surface during a heat transfer analysis in order to avoid the complications associated with nonlinearity. This is especially the case when heat transfer at the surface is dominated by convection, and the role of radiation is minor.

## 5 Interface Boundary Conditions

Some bodies are made up of layers of different materials, and the solution of a heat transfer problem in such a medium requires the solution of the heat transfer problem in each layer. This, in turn, requires the specification of the boundary conditions at each *interface*.

The boundary conditions at an interface are based on the requirements that (1) two bodies in contact must have the *same temperature* at the area of contact and (2) an interface (which is a surface) cannot store any energy, and thus the *heat flux* on the two sides of an interface *must be the same*. The boundary conditions at the interface of two bodies *A* and *B* in perfect contact at  $x = x_0$  can be expressed as (Fig. 2–36)

$$T_A(x_0, t) = T_B(x_0, t) \quad (2-53)$$

and

$$-k_A \frac{\partial T_A(x_0, t)}{\partial x} = -k_B \frac{\partial T_B(x_0, t)}{\partial x} \quad (2-54)$$

where  $k_A$  and  $k_B$  are the thermal conductivities of the layers *A* and *B*, respectively. The case of imperfect contact results in thermal contact resistance, which is considered in the next chapter.

## 6 Generalized Boundary Conditions

So far we have considered surfaces subjected to *single mode* heat transfer, such as the specified heat flux, convection, or radiation for simplicity. In general, however, a surface may involve convection, radiation, *and* specified heat flux simultaneously. The boundary condition in such cases is again obtained from a surface energy balance, expressed as

$$\left( \begin{array}{l} \text{Heat transfer} \\ \text{to the surface} \\ \text{in all modes} \end{array} \right) = \left( \begin{array}{l} \text{Heat transfer} \\ \text{from the surface} \\ \text{in all modes} \end{array} \right) \quad (2-55)$$

This is illustrated in Examples 2–8 and 2–9.

### EXAMPLE 2–8 Combined Convection and Radiation Condition

A spherical metal ball of radius  $r_o$  is heated in an oven to a temperature of 600°F throughout and is then taken out of the oven and allowed to cool in ambient air at  $T_\infty = 78^\circ\text{F}$ , as shown in Fig. 2–37. The thermal conductivity of the ball material is  $k = 8.3 \text{ Btu/h}\cdot\text{ft}\cdot\text{R}$ , and the average convection heat transfer coefficient on the outer surface of the ball is evaluated to be  $h = 4.5 \text{ Btu/h}\cdot\text{ft}^2\cdot\text{R}$ . The emissivity of the outer surface of the ball is  $\varepsilon = 0.6$ , and the average temperature of the surrounding surfaces is  $T_{\text{surr}} = 525 \text{ R}$ . Assuming the ball is cooled uniformly from the entire outer surface, express the initial and boundary conditions for the cooling process of the ball.

**FIGURE 2–36**

Boundary conditions at the interface of two bodies in perfect contact.

**FIGURE 2–37**

Schematic for Example 2–8.

**SOLUTION** The cooling of a hot spherical metal ball is considered. The initial and boundary conditions are to be obtained.

**Analysis** The ball is initially at a uniform temperature and is cooled uniformly from the entire outer surface. Therefore, this is a one-dimensional transient heat transfer problem since the temperature within the ball changes with the radial distance  $r$  and the time  $t$ . That is,  $T = T(r, t)$ . Taking the moment the ball is removed from the oven to be  $t = 0$ , the initial condition can be expressed as

$$T(r, 0) = T_i = 600^\circ\text{F}$$

The problem possesses symmetry about the midpoint ( $r = 0$ ) since the isotherms in this case are concentric spheres, and thus no heat is crossing the midpoint of the ball. Then the boundary condition at the midpoint can be expressed as

$$\frac{\partial T(0, t)}{\partial r} = 0$$

The heat conducted to the outer surface of the ball is lost to the environment by convection and radiation. Then taking the direction of heat transfer to be the positive  $r$  direction, the boundary condition on the outer surface can be expressed as

$$-k \frac{\partial T(r_o, t)}{\partial r} = h[T(r_o) - T_\infty] + \varepsilon\sigma[T(r_o)^4 - T_{\text{surr}}^4]$$

**Discussion** All the quantities in the above relations are known except the temperatures and their derivatives at  $r = 0$  and  $r_o$ . Also, the radiation part of the boundary condition is often ignored for simplicity by modifying the convection heat transfer coefficient to account for the contribution of radiation. The convection coefficient  $h$  in that case becomes the combined heat transfer coefficient.

### EXAMPLE 2-9 Combined Convection, Radiation, and Heat Flux

Consider the south wall of a house that is  $L = 0.2$  m thick. The outer surface of the wall is exposed to solar radiation and has an absorptivity of  $\alpha = 0.5$  for solar energy. The interior of the house is maintained at  $T_{\infty 1} = 20^\circ\text{C}$ , while the ambient air temperature outside remains at  $T_{\infty 2} = 5^\circ\text{C}$ . The sky, the ground, and the surfaces of the surrounding structures at this location can be modeled as a surface at an effective temperature of  $T_{\text{sky}} = 255$  K for radiation exchange on the outer surface. The radiation exchange between the inner surface of the wall and the surfaces of the walls, floor, and ceiling it faces is negligible. The convection heat transfer coefficients on the inner and the outer surfaces of the wall are  $h_1 = 6$  W/m<sup>2</sup>·K and  $h_2 = 25$  W/m<sup>2</sup>·K, respectively. The thermal conductivity of the wall material is  $k = 0.7$  W/m·K, and the emissivity of the outer surface is  $\varepsilon_2 = 0.9$ . Assuming the heat transfer through the wall to be steady and one-dimensional, express the boundary conditions on the inner and the outer surfaces of the wall.

**SOLUTION** The wall of a house subjected to solar radiation is considered. The boundary conditions on the inner and outer surfaces of the wall are to be obtained.

**Analysis** We take the direction normal to the wall surfaces as the  $x$ -axis with the origin at the inner surface of the wall, as shown in Fig. 2–38. The heat transfer through the wall is given to be steady and one-dimensional, and thus the temperature depends on  $x$  only and not on time. That is,  $T = T(x)$ .

The boundary condition on the inner surface of the wall at  $x = 0$  is a typical convection condition since it does not involve any radiation or specified heat flux. Taking the direction of heat transfer to be the positive  $x$ -direction, the boundary condition on the inner surface can be expressed as

$$-k \frac{dT(0)}{dx} = h_1 [T_{\infty 1} - T(0)]$$

The boundary condition on the outer surface at  $x = L$  is quite general as it involves conduction, convection, radiation, and specified heat flux. Again taking the direction of heat transfer to be the positive  $x$ -direction, the boundary condition on the outer surface can be expressed as

$$-k \frac{dT(L)}{dx} = h_2 [T(L) - T_{\infty 2}] + \varepsilon_2 \sigma [T(L)^4 - T_{\text{sky}}^4] - \alpha \dot{q}_{\text{solar}}$$

where  $\dot{q}_{\text{solar}}$  is the incident solar heat flux.

**Discussion** Assuming the opposite direction for heat transfer would give the same result multiplied by  $-1$ , which is equivalent to the relation here. All the quantities in these relations are known except the temperatures and their derivatives at the two boundaries.

FIGURE 2–38

Schematic for Example 2–9.

Note that a heat transfer problem may involve different kinds of boundary conditions on different surfaces. For example, a plate may be subject to *heat flux* on one surface while losing or gaining heat by *convection* from the other surface. Also, the two boundary conditions in a direction may be specified *at the same boundary*, while no condition is imposed on the other boundary. For example, specifying the temperature and heat flux at  $x = 0$  of a plate of thickness  $L$  will result in a unique solution for the one-dimensional steady temperature distribution in the plate, including the value of temperature at the surface  $x = L$ . Although not necessary, there is nothing wrong with specifying more than two boundary conditions in a specified direction, provided that there is no contradiction. The extra conditions in this case can be used to verify the results.

## 2–5 • SOLUTION OF STEADY ONE-DIMENSIONAL HEAT CONDUCTION PROBLEMS

So far we have derived the differential equations for heat conduction in various coordinate systems and discussed the possible boundary conditions. A heat conduction problem can be formulated by specifying the applicable differential equation and a set of proper boundary conditions.

In this section we will solve a wide range of heat conduction problems in rectangular, cylindrical, and spherical geometries. We will limit our attention to problems that result in *ordinary differential equations* such as the *steady one-dimensional* heat conduction problems. We will also assume *constant thermal conductivity*, but will consider variable conductivity later in this

**FIGURE 2–39**

Basic steps involved in the solution of heat transfer problems.

**FIGURE 2–40**

Schematic for Example 2–10.

chapter. If you feel rusty on differential equations or haven't taken differential equations yet, no need to panic. *Simple integration* is all you need to solve the steady one-dimensional heat conduction problems.

The solution procedure for solving heat conduction problems can be summarized as (1) *formulate* the problem by obtaining the applicable differential equation in its simplest form and specifying the boundary conditions, (2) obtain the *general solution* of the differential equation, and (3) apply the *boundary conditions* and determine the arbitrary constants in the general solution (Fig. 2–39). This is demonstrated below with examples.

### EXAMPLE 2–10 Heat Conduction in a Plane Wall

Consider a large plane wall of thickness  $L = 0.2$  m, thermal conductivity  $k = 1.2$  W/m·K, and surface area  $A = 15$  m<sup>2</sup>. The two sides of the wall are maintained at constant temperatures of  $T_1 = 120^\circ\text{C}$  and  $T_2 = 50^\circ\text{C}$ , respectively, as shown in Fig. 2–40. Determine (a) the variation of temperature within the wall and the value of temperature at  $x = 0.1$  m and (b) the rate of heat conduction through the wall under steady conditions.

**SOLUTION** A plane wall with specified surface temperatures is given. The variation of temperature and the rate of heat transfer are to be determined.

**Assumptions** 1 Heat conduction is steady. 2 Heat conduction is one-dimensional since the wall is large relative to its thickness and the thermal conditions on both sides are uniform. 3 Thermal conductivity is constant. 4 There is no heat generation.

**Properties** The thermal conductivity is given to be  $k = 1.2$  W/m·K.

**Analysis** (a) Taking the direction normal to the surface of the wall to be the  $x$ -direction, the differential equation for this problem can be expressed as

$$\frac{d^2T}{dx^2} = 0$$

with boundary conditions

$$T(0) = T_1 = 120^\circ\text{C}$$

$$T(L) = T_2 = 50^\circ\text{C}$$

The differential equation is linear and second order, and a quick inspection of it reveals that it has a single term involving derivatives and no terms involving the unknown function  $T$  as a factor. Thus, it can be solved by direct integration. Noting that an integration reduces the order of a derivative by one, the general solution of the differential equation above can be obtained by two simple successive integrations, each of which introduces an integration constant.

Integrating the differential equation once with respect to  $x$  yields

$$\frac{dT}{dx} = C_1$$

where  $C_1$  is an arbitrary constant. Notice that the order of the derivative went down by one as a result of integration. As a check, if we take the derivative of this equation, we will obtain the original differential equation. This equation is not the solution yet since it involves a derivative.

Integrating one more time, we obtain

$$T(x) = C_1x + C_2$$

which is the general solution of the differential equation (Fig. 2–41). The general solution in this case resembles the general formula of a straight line whose slope is  $C_1$  and whose value at  $x = 0$  is  $C_2$ . This is not surprising since the second derivative represents the change in the slope of a function, and a zero second derivative indicates that the slope of the function remains constant. Therefore, *any straight line* is a solution of this differential equation.

The general solution contains two unknown constants  $C_1$  and  $C_2$ , and thus we need two equations to determine them uniquely and obtain the specific solution. These equations are obtained by forcing the general solution to satisfy the specified boundary conditions. The application of each condition yields one equation, and thus we need to specify two conditions to determine the constants  $C_1$  and  $C_2$ .

When applying a boundary condition to an equation, *all occurrences of the dependent and independent variables and any derivatives are replaced by the specified values*. Thus the only unknowns in the resulting equations are the arbitrary constants.

The first boundary condition can be interpreted as *in the general solution, replace all the x's by zero and T(x) by  $T_1$* . That is (Fig. 2–42),

$$T(0) = C_1 \times 0 + C_2 \rightarrow C_2 = T_1$$

The second boundary condition can be interpreted as *in the general solution, replace all the x's by L and T(x) by  $T_2$* . That is,

$$T(L) = C_1L + C_2 \rightarrow T_2 = C_1L + T_1 \rightarrow C_1 = \frac{T_2 - T_1}{L}$$

Substituting the  $C_1$  and  $C_2$  expressions into the general solution, we obtain

$$T(x) = \frac{T_2 - T_1}{L}x + T_1 \quad (2-56)$$

which is the desired solution since it satisfies not only the differential equation but also the two specified boundary conditions. That is, differentiating Eq. 2–56 with respect to  $x$  twice will give  $d^2T/dx^2$ , which is the given differential equation, and substituting  $x = 0$  and  $x = L$  into Eq. 2–56 gives  $T(0) = T_1$  and  $T(L) = T_2$ , respectively, which are the specified conditions at the boundaries.

Substituting the given information, the value of the temperature at  $x = 0.1$  m is determined to be

$$T(0.1 \text{ m}) = \frac{(50 - 120)^\circ\text{C}}{0.2 \text{ m}} (0.1 \text{ m}) + 120^\circ\text{C} = 85^\circ\text{C}$$

(b) The rate of heat conduction anywhere in the wall is determined from Fourier's law to be

$$\dot{Q}_{\text{wall}} = -kA \frac{dT}{dx} = -kAC_1 = -kA \frac{T_2 - T_1}{L} = kA \frac{T_1 - T_2}{L} \quad (2-57)$$

The numerical value of the rate of heat conduction through the wall is determined by substituting the given values to be

$$\dot{Q} = kA \frac{T_1 - T_2}{L} = (1.2 \text{ W/m}\cdot\text{K})(15 \text{ m}^2) \frac{(120 - 50)^\circ\text{C}}{0.2 \text{ m}} = 6300 \text{ W}$$

**Discussion** Note that under steady conditions, the rate of heat conduction through a plane wall is constant.

Differential equation:

$$\frac{d^2T}{dx^2} = 0$$

Integrate:

$$\frac{dT}{dx} = C_1$$

Integrate again:

$$T(x) = C_1x + C_2$$

General solution

Arbitrary constants

FIGURE 2–41

Obtaining the general solution of a simple second order differential equation by integration.

Boundary condition:

$$T(0) = T_1$$

General solution:

$$T(x) = C_1x + C_2$$

Applying the boundary condition:

$$\begin{array}{c} T(x) = C_1x + C_2 \\ \uparrow \quad \uparrow \\ 0 \quad 0 \\ \hline T_1 \end{array}$$

Substituting:

$$\rightarrow T_1 = C_1 \times 0 + C_2 \rightarrow C_2 = T_1$$

It cannot involve  $x$  or  $T(x)$  after the boundary condition is applied.

FIGURE 2–42

When applying a boundary condition to the general solution at a specified point, all occurrences of the dependent and independent variables should be replaced by their specified values at that point.

**EXAMPLE 2-11 A Wall with Various Sets of Boundary Conditions**

Consider steady one-dimensional heat conduction in a large plane wall of thickness  $L$  and constant thermal conductivity  $k$  with no heat generation. Obtain expressions for the variation of temperature within the wall for the following pairs of boundary conditions (Fig. 2-43):

$$(a) -k \frac{dT(0)}{dx} = \dot{q}_0 = 40 \text{ W/cm}^2 \quad \text{and} \quad T(0) = T_0 = 15^\circ\text{C}$$

$$(b) -k \frac{dT(0)}{dx} = \dot{q}_0 = 40 \text{ W/cm}^2 \quad \text{and} \quad -k \frac{dT(L)}{dx} = \dot{q}_L = -25 \text{ W/cm}^2$$

$$(c) -k \frac{dT(0)}{dx} = \dot{q}_0 = 40 \text{ W/cm}^2 \quad \text{and} \quad -k \frac{dT(L)}{dx} = \dot{q}_L = \dot{q}_0 = 40 \text{ W/cm}^2$$

**SOLUTION** Steady one-dimensional heat conduction in a large plane wall is considered. The variation of temperature is to be determined for different sets of boundary conditions.

**Analysis** This is a steady one-dimensional heat conduction problem with constant thermal conductivity and no heat generation in the medium, and the heat conduction equation in this case can be expressed as (Eq. 2-17)

$$\frac{d^2T}{dx^2} = 0$$

whose general solution was determined in the previous example by direct integration to be

$$T(x) = C_1 x + C_2$$

where  $C_1$  and  $C_2$  are two arbitrary integration constants. The specific solutions corresponding to each specified pair of boundary conditions are determined as follows.

(a) In this case, both boundary conditions are specified at the same boundary at  $x = 0$ , and no boundary condition is specified at the other boundary at  $x = L$ . Noting that

$$\frac{dT}{dx} = C_1$$

the application of the boundary conditions gives

$$-k \frac{dT(0)}{dx} = \dot{q}_0 \rightarrow -kC_1 = \dot{q}_0 \rightarrow C_1 = -\frac{\dot{q}_0}{k}$$

and

$$T(0) = T_0 \rightarrow T_0 = C_1 \times 0 + C_2 \rightarrow C_2 = T_0$$

Substituting, the specific solution in this case is determined to be

$$T(x) = -\frac{\dot{q}_0}{k}x + T_0$$

FIGURE 2-43

Schematic for Example 2-11.

Therefore, the two boundary conditions can be specified at the same boundary, and it is not necessary to specify them at different locations. In fact, the fundamental theorem of linear ordinary differential equations guarantees that a unique solution exists when both conditions are specified at the same location. But no such guarantee exists when the two conditions are specified at different boundaries, as you will see below.

(b) In this case different heat fluxes are specified at the two boundaries. The application of the boundary conditions gives

$$-k \frac{dT(0)}{dx} = \dot{q}_0 \rightarrow -kC_1 = \dot{q}_0 \rightarrow C_1 = -\frac{\dot{q}_0}{k}$$

and

$$-k \frac{dT(L)}{dx} = \dot{q}_L \rightarrow -kC_1 = \dot{q}_L \rightarrow C_1 = -\frac{\dot{q}_L}{k}$$

Since  $\dot{q}_0 \neq \dot{q}_L$  and the constant  $C_1$  cannot be equal to two different things at the same time, **there is no solution in this case**. This is not surprising since this case corresponds to supplying heat to the plane wall from both sides and expecting the temperature of the wall to remain steady (not to change with time). This is impossible.

(c) In this case, the same values for heat flux are specified at the two boundaries. The application of the boundary conditions gives

$$-k \frac{dT(0)}{dx} = \dot{q}_0 \rightarrow -kC_1 = \dot{q}_0 \rightarrow C_1 = -\frac{\dot{q}_0}{k}$$

and

$$-k \frac{dT(L)}{dx} = \dot{q}_0 \rightarrow -kC_1 = \dot{q}_0 \rightarrow C_1 = -\frac{\dot{q}_0}{k}$$

Thus, both conditions result in the same value for the constant  $C_1$ , but no value for  $C_2$ . Substituting, the specific solution in this case is determined to be

$$T(x) = -\frac{\dot{q}_0}{k}x + C_2$$

which is not a unique solution since  $C_2$  is arbitrary.

**FIGURE 2-44**

A boundary-value problem may have a unique solution, infinitely many solutions, or no solutions at all.

**Discussion** The last solution represents a family of straight lines whose slope is  $-\dot{q}_0/k$ . Physically, this problem corresponds to requiring the rate of heat supplied to the wall at  $x = 0$  be equal to the rate of heat removal from the other side of the wall at  $x = L$ . But this is a consequence of the heat conduction through the wall being steady, and thus the second boundary condition does not provide any new information. So it is not surprising that the solution of this problem is not unique. The three cases discussed above are summarized in Fig. 2-44.

### EXAMPLE 2-12 Heat Conduction in the Base Plate of an Iron

Consider the base plate of a 1200-W household iron that has a thickness of  $L = 0.5$  cm, base area of  $A = 300 \text{ cm}^2$ , and thermal conductivity of  $k = 15 \text{ W/m}\cdot\text{K}$ . The inner surface of the base plate is subjected to uniform heat flux generated by the resistance heaters inside, and the outer surface loses heat to the surroundings at  $T_\infty = 20^\circ\text{C}$  by convection, as shown in Fig. 2-45. Taking the convection heat transfer coefficient to be  $h = 80 \text{ W/m}^2\cdot\text{K}$  and disregarding heat loss by radiation, obtain an expression for the variation of temperature in the base plate, and evaluate the temperatures at the inner and the outer surfaces.

**SOLUTION** The base plate of an iron is considered. The variation of temperature in the plate and the surface temperatures are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since the surface area of the base plate is large relative to its thickness, and the thermal conditions on both sides are uniform. 3 Thermal conductivity is constant. 4 There is no heat generation in the medium. 5 Heat transfer by radiation is negligible. 6 The upper part of the iron is well insulated so that the entire heat generated in the resistance wires is transferred to the base plate through its inner surface.

**Properties** The thermal conductivity is given to be  $k = 15 \text{ W/m}\cdot\text{K}$ .

**Analysis** The inner surface of the base plate is subjected to uniform heat flux at a rate of

$$\dot{Q}_0 = \frac{\dot{Q}_0}{A_{\text{base}}} = \frac{1200 \text{ W}}{0.03 \text{ m}^2} = 40,000 \text{ W/m}^2$$

The outer side of the plate is subjected to the convection condition. Taking the direction normal to the surface of the wall as the  $x$ -direction with its origin on the inner surface, the differential equation for this problem can be expressed as (Fig. 2-46)

$$\frac{d^2T}{dx^2} = 0$$

with the boundary conditions

$$-k \frac{dT(0)}{dx} = \dot{q}_0 = 40,000 \text{ W/m}^2$$

$$-k \frac{dT(L)}{dx} = h[T(L) - T_\infty]$$

**FIGURE 2-45**

Schematic for Example 2-12.

The general solution of the differential equation is again obtained by two successive integrations to be

$$\frac{dT}{dx} = C_1$$

and

$$T(x) = C_1 x + C_2 \quad (a)$$

where  $C_1$  and  $C_2$  are arbitrary constants. Applying the first boundary condition,

$$-k \frac{dT(0)}{dx} = \dot{q}_0 \rightarrow -kC_1 = \dot{q}_0 \rightarrow C_1 = -\frac{\dot{q}_0}{k}$$

Noting that  $dT/dx = C_1$  and  $T(L) = C_1 L + C_2$ , the application of the second boundary condition gives

$$-k \frac{dT(L)}{dx} = h[T(L) - T_\infty] \rightarrow -kC_1 = h[(C_1 L + C_2) - T_\infty]$$

Substituting  $C_1 = -\dot{q}_0/k$  and solving for  $C_2$ , we obtain

$$C_2 = T_\infty + \frac{\dot{q}_0}{h} + \frac{\dot{q}_0}{k} L$$

Now substituting  $C_1$  and  $C_2$  into the general solution (a) gives

$$T(x) = T_\infty + \dot{q}_0 \left( \frac{L-x}{k} + \frac{1}{h} \right) \quad (b)$$

which is the solution for the variation of the temperature in the plate. The temperatures at the inner and outer surfaces of the plate are determined by substituting  $x = 0$  and  $x = L$ , respectively, into the relation (b):

$$\begin{aligned} T(0) &= T_\infty + \dot{q}_0 \left( \frac{L}{k} + \frac{1}{h} \right) \\ &= 20^\circ\text{C} + (40,000 \text{ W/m}^2) \left( \frac{0.005 \text{ m}}{15 \text{ W/m}\cdot\text{K}} + \frac{1}{80 \text{ W/m}^2\cdot\text{K}} \right) = 533^\circ\text{C} \end{aligned}$$

and

$$T(L) = T_\infty + \dot{q}_0 \left( 0 + \frac{1}{h} \right) = 20^\circ\text{C} + \frac{40,000 \text{ W/m}^2}{80 \text{ W/m}^2\cdot\text{K}} = 520^\circ\text{C}$$

**Discussion** Note that the temperature of the inner surface of the base plate is  $13^\circ\text{C}$  higher than the temperature of the outer surface when steady operating conditions are reached. Also note that this heat transfer analysis enables us to calculate the temperatures of surfaces that we cannot even reach. This example demonstrates how the heat flux and convection boundary conditions are applied to heat transfer problems.

FIGURE 2–46

The boundary conditions on the base plate of the iron discussed in Example 2–12.

**FIGURE 2-47**

Schematic for Example 2-13.

**PtD EXAMPLE 2-13****Thermal Burn Prevention in Metal Processing Plant**

In metal processing plants, workers often operate near hot metal surfaces. Exposed hot surfaces are hazards that can potentially cause thermal burns on human skin tissue. Metallic surface with a temperature above 70°C is considered extremely hot. Damage to skin tissue can occur instantaneously upon contact with metallic surface at that temperature. In a plant that processes metal plates, a plate is conveyed through a series of fans to cool its surface in an ambient temperature of 30°C, as shown in Figure 2-47. The plate is 25 mm thick and has a thermal conductivity of 13.5 W/m·K. Temperature at the bottom surface of the plate is monitored by an infrared (IR) thermometer. Obtain an expression for the variation of temperature in the metal plate. The IR thermometer measures the bottom surface of the plate to be 60°C. Determine the minimum value of the convection heat transfer coefficient necessary to keep the top surface below 47°C to avoid instantaneous thermal burn upon accidental contact of hot metal surface with skin tissue.

**SOLUTION** In this example, the concepts of Prevention through Design (PtD) are applied in conjunction with the solution of steady one-dimensional heat conduction problem. The top surface of the plate is cooled by convection, and temperature at the bottom surface is measured by an IR thermometer. The variation of temperature in the metal plate and the convection heat transfer coefficient necessary to keep the top surface below 47°C are to be determined.

**Assumptions** 1 Heat conduction is steady and one-dimensional. 2 Thermal conductivity is constant. 3 There is no heat generation in the plate. 4 The bottom surface at  $x = 0$  is at constant temperature while the top surface at  $x = L$  is subjected to convection.

**Properties** The thermal conductivity of the metal plate is given to be  $k = 13.5 \text{ W/m}\cdot\text{K}$ .

**Analysis** Taking the direction normal to the surface of the wall to be the  $x$  direction with  $x = 0$  at the lower surface, the mathematical formulation can be expressed as

$$\frac{d^2T}{dx^2} = 0$$

with boundary conditions

$$T(0) = T_0$$

$$-k \frac{dT(L)}{dx} = h[T(L) - T_\infty]$$

Integrating the differential equation twice with respect to  $x$  yields

$$\frac{dT}{dx} = C_1$$

$$T(x) = C_1x + C_2$$

where  $C_1$  and  $C_2$  are arbitrary constants. Applying the first boundary condition yields

$$T(0) = C_1 \times 0 + C_2 = T_0 \rightarrow C_2 = T_0$$

The application of the second boundary condition gives

$$-k \frac{dT(L)}{dx} = h[T(L) - T_{\infty}] \rightarrow -kC_1 = h(C_1L + C_2 - T_{\infty})$$

Solving for  $C_1$  yields

$$C_1 = \frac{h(T_{\infty} - C_2)}{k + hL} = \frac{T_{\infty} - T_0}{(k/h) + L}$$

Now substituting  $C_1$  and  $C_2$  into the general solution, the variation of temperature becomes

$$T(x) = \frac{T_{\infty} - T_0}{(k/h) + L}x + T_0$$

The minimum convection heat transfer coefficient necessary to maintain the top surface below 47°C can be determined from the variation of temperature:

$$T(L) = T_L = \frac{T_{\infty} - T_0}{(k/h) + L}L + T_0$$

Solving for  $h$  gives

$$h = \frac{k}{L} \frac{T_L - T_0}{T_{\infty} - T_L} = \left( \frac{13.5 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} \right) \frac{(47 - 60)^\circ\text{C}}{(30 - 47)^\circ\text{C}} = 413 \text{ W/m}^2\cdot\text{K}$$

**Discussion** To keep the top surface of the metal plate below 47°C, the convection heat transfer coefficient should be greater than 413 W/m<sup>2</sup>·K. A convection heat transfer coefficient value of 413 W/m<sup>2</sup>·K is very high for forced convection of gases. The typical values for forced convection of gases are 25–250 W/m<sup>2</sup>·K (see Table 1-5 in Chapter 1). To protect workers from thermal burn, appropriate apparel should be worn when operating in an area where hot surfaces are present.

### EXAMPLE 2-14 Heat Conduction in a Solar Heated Wall

Consider a large plane wall of thickness  $L = 0.06 \text{ m}$  and thermal conductivity  $k = 1.2 \text{ W/m}\cdot\text{K}$  in space. The wall is covered with white porcelain tiles that have an emissivity of  $\varepsilon = 0.85$  and a solar absorptivity of  $\alpha = 0.26$ , as shown in Fig. 2-48. The inner surface of the wall is maintained at  $T_1 = 300 \text{ K}$  at all times, while the outer surface is exposed to solar radiation that is incident at a rate of  $\dot{q}_{\text{solar}} = 800 \text{ W/m}^2$ . The outer surface is also losing heat by radiation to deep space at  $0 \text{ K}$ . Determine the temperature of the outer surface of the wall and the rate of heat transfer through the wall when steady operating conditions are reached. What would your response be if no solar radiation was incident on the surface?

**SOLUTION** A plane wall in space is subjected to specified temperature on one side and solar radiation on the other side. The outer surface temperature and the rate of heat transfer are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since the wall is large relative to its thickness, and the thermal conditions on both sides are uniform. 3 Thermal conductivity is constant. 4 There is no heat generation.

**FIGURE 2-48**  
Schematic for Example 2-14.

**Properties** The thermal conductivity is given to be  $k = 1.2 \text{ W/m}\cdot\text{K}$ .

**Analysis** Taking the direction normal to the surface of the wall as the  $x$ -direction with its origin on the inner surface, the differential equation for this problem can be expressed as

$$\frac{d^2T}{dx^2} = 0$$

with boundary conditions

$$T(0) = T_1 = 300 \text{ K}$$

$$-k \frac{dT(L)}{dx} = \varepsilon\sigma[T(L)^4 - T_{\text{space}}^4] - \alpha\dot{q}_{\text{solar}}$$

where  $T_{\text{space}} = 0$ . The general solution of the differential equation is again obtained by two successive integrations to be

$$T(x) = C_1x + C_2 \quad (a)$$

where  $C_1$  and  $C_2$  are arbitrary constants. Applying the first boundary condition yields

$$T(0) = C_1 \times 0 + C_2 \rightarrow C_2 = T_1$$

Noting that  $dT/dx = C_1$  and  $T(L) = C_1L + C_2 = C_1L + T_1$ , the application of the second boundary conditions gives

$$-k \frac{dT(L)}{dx} = \varepsilon\sigma T(L)^4 - \alpha\dot{q}_{\text{solar}} \rightarrow -kC_1 = \varepsilon\sigma(C_1L + T_1)^4 - \alpha\dot{q}_{\text{solar}}$$

Although  $C_1$  is the only unknown in this equation, we cannot get an explicit expression for it because the equation is nonlinear, and thus we cannot get a closed-form expression for the temperature distribution. This should explain why we do our best to avoid nonlinearities in the analysis, such as those associated with radiation.

Let us back up a little and denote the outer surface temperature by  $T(L) = T_L$  instead of  $T(L) = C_1L + T_1$ . The application of the second boundary condition in this case gives

$$-k \frac{dT(L)}{dx} = \varepsilon\sigma T(L)^4 - \alpha\dot{q}_{\text{solar}} \rightarrow -kC_1 = \varepsilon\sigma T_L^4 - \alpha\dot{q}_{\text{solar}}$$

Solving for  $C_1$  gives

$$C_1 = \frac{\alpha\dot{q}_{\text{solar}} - \varepsilon\sigma T_L^4}{k} \quad (b)$$

Now substituting  $C_1$  and  $C_2$  into the general solution (a), we obtain

$$T(x) = \frac{\alpha\dot{q}_{\text{solar}} - \varepsilon\sigma T_L^4}{k} x + T_1 \quad (c)$$

which is the solution for the variation of the temperature in the wall in terms of the unknown outer surface temperature  $T_L$ . At  $x = L$  it becomes

$$T_L = \frac{\alpha\dot{q}_{\text{solar}} - \varepsilon\sigma T_L^4}{k} L + T_1 \quad (d)$$

which is an implicit relation for the outer surface temperature  $T_L$ . Substituting the given values, we get

$$T_L = \frac{0.26 \times (800 \text{ W/m}^2) - 0.85 \times (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) T_L^4}{1.2 \text{ W/m} \cdot \text{K}} (0.06 \text{ m}) + 300 \text{ K}$$

which simplifies to

$$T_L = 310.4 - 0.240975 \left( \frac{T_L}{100} \right)^4$$

This equation can be solved by one of the several nonlinear equation solvers available (or by the old fashioned trial-and-error method) to give (Fig. 2–49)

$$T_L = 292.7 \text{ K}$$

Knowing the outer surface temperature and knowing that it must remain constant under steady conditions, the temperature distribution in the wall can be determined by substituting the  $T_L$  value above into Eq. (c):

$$T(x) = \frac{0.26 \times (800 \text{ W/m}^2) - 0.85 \times (5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4)(292.7 \text{ K})^4}{1.2 \text{ W/m} \cdot \text{K}} x + 300 \text{ K}$$

which simplifies to

$$T(x) = (-121.5 \text{ K/m})x + 300 \text{ K}$$

Note that the outer surface temperature turned out to be lower than the inner surface temperature. Therefore, the heat transfer through the wall is toward the outside despite the absorption of solar radiation by the outer surface. Knowing both the inner and outer surface temperatures of the wall, the steady rate of heat conduction through the wall can be determined from

$$\dot{q} = k \frac{T_1 - T_L}{L} = (1.2 \text{ W/m} \cdot \text{K}) \frac{(300 - 292.7) \text{ K}}{0.06 \text{ m}} = 146 \text{ W/m}^2$$

**Discussion** In the case of no incident solar radiation, the outer surface temperature, determined from Eq. (d) by setting  $\dot{q}_{\text{solar}} = 0$ , is  $T_L = 284.3 \text{ K}$ . It is interesting to note that the solar energy incident on the surface causes the surface temperature to increase by about 8 K only when the inner surface temperature of the wall is maintained at 300 K.

### EXAMPLE 2–15 Heat Loss through a Steam Pipe

Consider a steam pipe of length  $L = 20 \text{ m}$ , inner radius  $r_1 = 6 \text{ cm}$ , outer radius  $r_2 = 8 \text{ cm}$ , and thermal conductivity  $k = 20 \text{ W/m} \cdot \text{K}$ , as shown in Fig. 2–50. The inner and outer surfaces of the pipe are maintained at average temperatures of  $T_1 = 150^\circ\text{C}$  and  $T_2 = 60^\circ\text{C}$ , respectively. Obtain a general relation for the temperature distribution inside the pipe under steady conditions, and determine the rate of heat loss from the steam through the pipe.

**SOLUTION** A steam pipe is subjected to specified temperatures on its surfaces. The variation of temperature and the rate of heat transfer are to be determined.

(1) Rearrange the equation to be solved:

$$T_L = 310.4 - 0.240975 \left( \frac{T_L}{100} \right)^4$$

The equation is in the proper form since the left side consists of  $T_L$  only.

(2) Guess the value of  $T_L$ , say 300 K, and substitute into the right side of the equation. It gives

$$T_L = 290.2 \text{ K}$$

(3) Now substitute this value of  $T_L$  into the right side of the equation and get

$$T_L = 293.1 \text{ K}$$

(4) Repeat step (3) until convergence to desired accuracy is achieved. The subsequent iterations give

$$T_L = 292.6 \text{ K}$$

$$T_L = 292.7 \text{ K}$$

$$T_L = 292.7 \text{ K}$$

Therefore, the solution is  $T_L = 292.7 \text{ K}$ . The result is independent of the initial guess.

FIGURE 2–49

A simple method of solving a nonlinear equation is to arrange the equation such that the unknown is alone on the left side while everything else is on the right side, and to iterate after an initial guess until convergence.

FIGURE 2–50

Schematic for Example 2–14.

**FIGURE 2–51**

Basic steps involved in the solution of the steady one-dimensional heat conduction equation in cylindrical coordinates.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction, and thus  $T = T(r)$ . 3 Thermal conductivity is constant. 4 There is no heat generation.

**Properties** The thermal conductivity is given to be  $k = 20 \text{ W/m}\cdot\text{K}$ .

**Analysis** The mathematical formulation of this problem can be expressed as

$$\frac{d}{dr} \left( r \frac{dT}{dr} \right) = 0$$

with boundary conditions

$$T(r_1) = T_1 = 150^\circ\text{C}$$

$$T(r_2) = T_2 = 60^\circ\text{C}$$

Integrating the differential equation once with respect to  $r$  gives

$$r \frac{dT}{dr} = C_1$$

where  $C_1$  is an arbitrary constant. We now divide both sides of this equation by  $r$  to bring it to a readily integrable form,

$$\frac{dT}{dr} = \frac{C_1}{r}$$

Again integrating with respect to  $r$  gives (Fig. 2–51)

$$T(r) = C_1 \ln r + C_2 \quad (a)$$

We now apply both boundary conditions by replacing all occurrences of  $r$  and  $T(r)$  in Eq. (a) with the specified values at the boundaries. We get

$$T(r_1) = T_1 \rightarrow C_1 \ln r_1 + C_2 = T_1$$

$$T(r_2) = T_2 \rightarrow C_1 \ln r_2 + C_2 = T_2$$

which are two equations in two unknowns,  $C_1$  and  $C_2$ . Solving them simultaneously gives

$$C_1 = \frac{T_2 - T_1}{\ln(r_2/r_1)} \quad \text{and} \quad C_2 = T_1 - \frac{T_2 - T_1}{\ln(r_2/r_1)} \ln r_1$$

Substituting them into Eq. (a) and rearranging, the variation of temperature within the pipe is determined to be

$$T(r) = \frac{\ln(r/r_1)}{\ln(r_2/r_1)} (T_2 - T_1) + T_1 \quad (2-58)$$

The rate of heat loss from the steam is simply the total rate of heat conduction through the pipe, and is determined from Fourier's law to be

$$\dot{Q}_{\text{cylinder}} = -kA \frac{dT}{dr} = -k(2\pi r L) \frac{C_1}{r} = -2\pi k L C_1 = 2\pi k L \frac{T_1 - T_2}{\ln(r_2/r_1)} \quad (2-59)$$

The numerical value of the rate of heat conduction through the pipe is determined by substituting the given values

$$\dot{Q} = 2\pi(20 \text{ W/m}\cdot\text{K})(20 \text{ m}) \frac{(150 - 60)^\circ\text{C}}{\ln(0.08/0.06)} = 786 \text{ kW}$$

**Discussion** Note that the total rate of heat transfer through a pipe is constant, but the heat flux  $\dot{q} = \dot{Q}/(2\pi rL)$  is not since it decreases in the direction of heat transfer with increasing radius.

### EXAMPLE 2–16 Heat Conduction through a Spherical Shell

Consider a spherical container of inner radius  $r_1 = 8$  cm, outer radius  $r_2 = 10$  cm, and thermal conductivity  $k = 45$  W/m·K, as shown in Fig. 2–52. The inner and outer surfaces of the container are maintained at constant temperatures of  $T_1 = 200^\circ\text{C}$  and  $T_2 = 80^\circ\text{C}$ , respectively, as a result of some chemical reactions occurring inside. Obtain a general relation for the temperature distribution inside the shell under steady conditions, and determine the rate of heat loss from the container.

**SOLUTION** A spherical container is subjected to specified temperatures on its surfaces. The variation of temperature and the rate of heat transfer are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the midpoint, and thus  $T = T(r)$ . 3 Thermal conductivity is constant. 4 There is no heat generation.

**Properties** The thermal conductivity is given to be  $k = 45$  W/m·K.

**Analysis** The mathematical formulation of this problem can be expressed as

$$\frac{d}{dr} \left( r^2 \frac{dT}{dr} \right) = 0$$

with boundary conditions

$$T(r_1) = T_1 = 200^\circ\text{C}$$

$$T(r_2) = T_2 = 80^\circ\text{C}$$

Integrating the differential equation once with respect to  $r$  yields

$$r^2 \frac{dT}{dr} = C_1$$

where  $C_1$  is an arbitrary constant. We now divide both sides of this equation by  $r^2$  to bring it to a readily integrable form,

$$\frac{dT}{dr} = \frac{C_1}{r^2}$$

Again integrating with respect to  $r$  gives

$$T(r) = -\frac{C_1}{r} + C_2 \quad (a)$$

We now apply both boundary conditions by replacing all occurrences of  $r$  and  $T(r)$  in the relation above by the specified values at the boundaries. We get

$$T(r_1) = T_1 \rightarrow -\frac{C_1}{r_1} + C_2 = T_1$$

$$T(r_2) = T_2 \rightarrow -\frac{C_1}{r_2} + C_2 = T_2$$

**FIGURE 2–52**  
Schematic for Example 2–16.

**FIGURE 2-53**

During steady one-dimensional heat conduction in a spherical (or cylindrical) container, the total rate of heat transfer remains constant, but the heat flux decreases with increasing radius.

which are two equations in two unknowns,  $C_1$  and  $C_2$ . Solving them simultaneously gives

$$C_1 = -\frac{r_1 r_2}{r_2 - r_1} (T_1 - T_2) \quad \text{and} \quad C_2 = \frac{r_2 T_2 - r_1 T_1}{r_2 - r_1}$$

Substituting into Eq. (a), the variation of temperature within the spherical shell is determined to be

$$T(r) = \frac{r_1 r_2}{r(r_2 - r_1)} (T_1 - T_2) + \frac{r_2 T_2 - r_1 T_1}{r_2 - r_1} \quad (2-60)$$

The rate of heat loss from the container is simply the total rate of heat conduction through the container wall and is determined from Fourier's law

$$\dot{Q}_{\text{sphere}} = -kA \frac{dT}{dr} = -k(4\pi r^2) \frac{C_1}{r^2} = -4\pi k C_1 = 4\pi k r_1 r_2 \frac{T_1 - T_2}{r_2 - r_1} \quad (2-61)$$

The numerical value of the rate of heat conduction through the wall is determined by substituting the given values to be

$$\dot{Q} = 4\pi(45 \text{ W/m}\cdot\text{K})(0.08 \text{ m})(0.10 \text{ m}) \frac{(200 - 80)^\circ\text{C}}{(0.10 - 0.08) \text{ m}} = 27.1 \text{ kW}$$

**Discussion** Note that the total rate of heat transfer through a spherical shell is constant, but the heat flux  $\dot{q} = \dot{Q}/4\pi r^2$  is not since it decreases in the direction of heat transfer with increasing radius as shown in Fig. 2-53.

**FIGURE 2-54**

Heat generation in solids is commonly encountered in practice.

## 2-6 ▪ HEAT GENERATION IN A SOLID

Many practical heat transfer applications involve the conversion of some form of energy into *thermal* energy in the medium. Such mediums are said to involve internal *heat generation*, which manifests itself as a rise in temperature throughout the medium. Some examples of heat generation are *resistance heating* in wires, exothermic *chemical reactions* in a solid, and *nuclear reactions* in nuclear fuel rods where electrical, chemical, and nuclear energies are converted to heat, respectively (Fig. 2-54). The absorption of radiation throughout the volume of a semitransparent medium such as water can also be considered as heat generation within the medium, as explained earlier.

Heat generation is usually expressed *per unit volume* of the medium, and is denoted by  $\dot{e}_{\text{gen}}$ , whose unit is  $\text{W/m}^3$ . For example, heat generation in an electrical wire of outer radius  $r_o$  and length  $L$  can be expressed as

$$\dot{e}_{\text{gen}} = \frac{\dot{E}_{\text{gen, electric}}}{V_{\text{wire}}} = \frac{I^2 R_e}{\pi r_o^2 L} \quad (\text{W/m}^3) \quad (2-62)$$

where  $I$  is the electric current and  $R_e$  is the electrical resistance of the wire.

The temperature of a medium *rises* during heat generation as a result of the absorption of the generated heat by the medium during transient start-up period. As the temperature of the medium increases, so does the heat transfer from the medium to its surroundings. This continues until steady operating

conditions are reached and the rate of heat generation equals the rate of heat transfer to the surroundings. Once steady operation has been established, the temperature of the medium at any point no longer changes.

The *maximum temperature*  $T_{\max}$  in a solid that involves uniform heat generation occurs at a location *farthest away* from the outer surface when the outer surface of the solid is maintained at a constant temperature  $T_s$ . For example, the maximum temperature occurs at the *midplane* in a plane wall, at the *centerline* in a long cylinder, and at the *midpoint* in a sphere. The temperature distribution within the solid in these cases is *symmetrical* about the center of symmetry.

The quantities of major interest in a medium with heat generation are the surface temperature  $T_s$  and the maximum temperature  $T_{\max}$  that occurs in the medium in *steady* operation. Below we develop expressions for these two quantities for common geometries for the case of *uniform* heat generation ( $\dot{e}_{\text{gen}} = \text{constant}$ ) within the medium.

Consider a solid medium of surface area  $A_s$ , volume  $V$ , and constant thermal conductivity  $k$ , where heat is generated at a constant rate of  $\dot{e}_{\text{gen}}$  per unit volume. Heat is transferred from the solid to the surrounding medium at  $T_\infty$ , with a constant heat transfer coefficient of  $h$ . All the surfaces of the solid are maintained at a common temperature  $T_s$ . Under *steady* conditions, the energy balance for this solid can be expressed as (Fig. 2–55)

$$\left( \begin{array}{l} \text{Rate of} \\ \text{heat transfer} \\ \text{from the solid} \end{array} \right) = \left( \begin{array}{l} \text{Rate of} \\ \text{energy generation} \\ \text{within the solid} \end{array} \right) \quad (2-63)$$

or

$$\dot{Q} = \dot{e}_{\text{gen}}V \quad (\text{W}) \quad (2-64)$$

Disregarding radiation (or incorporating it in the heat transfer coefficient  $h$ ), the heat transfer rate can also be expressed from Newton's law of cooling as

$$\dot{Q} = hA_s(T_s - T_\infty) \quad (\text{W}) \quad (2-65)$$

Combining Eqs. 2–64 and 2–65 and solving for the surface temperature  $T_s$  gives

$$T_s = T_\infty + \frac{\dot{e}_{\text{gen}}V}{hA_s} \quad (2-66)$$

For a large *plane wall* of thickness  $2L$  ( $A_s = 2A_{\text{wall}}$  and  $V = 2LA_{\text{wall}}$ ) with both sides of the wall maintained at the same temperature  $T_s$ , a long solid *cylinder* of radius  $r_o$  ( $A_s = 2\pi r_o L$  and  $V = \pi r_o^2 L$ ), and a solid *sphere* of radius  $r_o$  ( $A_s = 4\pi r_o^2$  and  $V = \frac{4}{3}\pi r_o^3$ ), Eq. 2–66 reduces to

$$T_{s, \text{plane wall}} = T_\infty + \frac{\dot{e}_{\text{gen}}L}{h} \quad (2-67)$$

$$T_{s, \text{cylinder}} = T_\infty + \frac{\dot{e}_{\text{gen}}r_o}{2h} \quad (2-68)$$

$$T_{s, \text{sphere}} = T_\infty + \frac{\dot{e}_{\text{gen}}r_o}{3h} \quad (2-69)$$

**FIGURE 2–55**

At steady conditions, the entire heat generated in a solid must leave the solid through its outer surface.

**FIGURE 2-56**

Heat conducted through a cylindrical shell of radius  $r$  is equal to the heat generated within a shell.

**FIGURE 2-57**

The maximum temperature in a symmetrical solid with uniform heat generation occurs at its center.

Note that the rise in surface temperature  $T_s$  is due to heat generation in the solid.

Reconsider heat transfer from a long solid cylinder with heat generation. We mentioned above that, under *steady* conditions, the entire heat generated within the medium is conducted through the outer surface of the cylinder. Now consider an imaginary inner cylinder of radius  $r$  within the cylinder (Fig. 2-56). Again the *heat generated* within this inner cylinder must be equal to the *heat conducted* through its outer surface. That is, from Fourier's law of heat conduction,

$$-kA_r \frac{dT}{dr} = \dot{e}_{\text{gen}} V_r \quad (2-70)$$

where  $A_r = 2\pi rL$  and  $V_r = \pi r^2 L$  at any location  $r$ . Substituting these expressions into Eq. 2-70 and separating the variables, we get

$$-k(2\pi rL) \frac{dT}{dr} = \dot{e}_{\text{gen}}(\pi r^2 L) \rightarrow dT = -\frac{\dot{e}_{\text{gen}}}{2k} r dr$$

Integrating from  $r = 0$  where  $T(0) = T_0$  to  $r = r_o$  where  $T(r_o) = T_s$  yields

$$\Delta T_{\text{max, cylinder}} = T_0 - T_s = \frac{\dot{e}_{\text{gen}} r_o^2}{4k} \quad (2-71)$$

where  $T_0$  is the centerline temperature of the cylinder, which is the *maximum temperature*, and  $\Delta T_{\text{max}}$  is the difference between the centerline and the surface temperatures of the cylinder, which is the *maximum temperature rise* in the cylinder above the surface temperature. Once  $\Delta T_{\text{max}}$  is available, the centerline temperature can easily be determined from (Fig. 2-57)

$$T_{\text{center}} = T_0 = T_s + \Delta T_{\text{max}} \quad (2-72)$$

The approach outlined above can also be used to determine the *maximum temperature rise* in a plane wall of thickness  $2L$  with both sides of the wall maintained at the same temperature  $T_s$  and a solid sphere of radius  $r_o$ , with these results:

$$\Delta T_{\text{max, plane wall}} = \frac{\dot{e}_{\text{gen}} L^2}{2k} \quad (2-73)$$

$$\Delta T_{\text{max, sphere}} = \frac{\dot{e}_{\text{gen}} r_o^2}{6k} \quad (2-74)$$

Again the maximum temperature at the center can be determined from Eq. 2-72 by adding the maximum temperature rise to the surface temperature of the solid.

### EXAMPLE 2-17 Centerline Temperature of a Resistance Heater

A 2-kW resistance heater wire whose thermal conductivity is  $k = 15 \text{ W/m}\cdot\text{K}$  has a diameter of  $D = 4 \text{ mm}$  and a length of  $L = 0.5 \text{ m}$ , and is used to boil water (Fig. 2-58). If the outer surface temperature of the resistance wire is  $T_s = 105^\circ\text{C}$ , determine the temperature at the center of the wire.

**SOLUTION** The center temperature of a resistance heater submerged in water is to be determined.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no change in the axial direction. 3 Thermal conductivity is constant. 4 Heat generation in the heater is uniform.

**Properties** The thermal conductivity is given to be  $k = 15 \text{ W/m}\cdot\text{K}$ .

**Analysis** The 2-kW resistance heater converts electric energy into heat at a rate of 2 kW. The heat generation per unit volume of the wire is

$$\dot{e}_{\text{gen}} = \frac{\dot{E}_{\text{gen}}}{V_{\text{wire}}} = \frac{\dot{E}_{\text{gen}}}{\pi r_o^2 L} = \frac{2000 \text{ W}}{\pi(0.002 \text{ m})^2(0.5 \text{ m})} = 0.318 \times 10^9 \text{ W/m}^3$$

Then the center temperature of the wire is determined from Eq. 2-71 to be

$$T_0 = T_s + \frac{\dot{e}_{\text{gen}} r_o^2}{4k} = 105^\circ\text{C} + \frac{(0.318 \times 10^9 \text{ W/m}^3)(0.002 \text{ m})^2}{4 \times (15 \text{ W/m}\cdot\text{K})} = 126^\circ\text{C}$$

**Discussion** Note that the temperature difference between the center and the surface of the wire is  $21^\circ\text{C}$ . Also, the thermal conductivity units  $\text{W/m}\cdot\text{^\circ C}$  and  $\text{W/m}\cdot\text{K}$  are equivalent.

We have developed these relations using the intuitive *energy balance* approach. However, we could have obtained the same relations by setting up the appropriate *differential equations* and solving them, as illustrated in Examples 2-18 and 2-19.

### EXAMPLE 2-18 Variation of Temperature in a Resistance Heater

A long homogeneous resistance wire of radius  $r_o = 0.2 \text{ in}$  and thermal conductivity  $k = 7.8 \text{ Btu/h}\cdot\text{ft}\cdot\text{^\circ F}$  is being used to boil water at atmospheric pressure by the passage of electric current, as shown in Fig. 2-59. Heat is generated in the wire uniformly as a result of resistance heating at a rate of  $\dot{e}_{\text{gen}} = 2400 \text{ Btu/h}\cdot\text{in}^3$ . If the outer surface temperature of the wire is measured to be  $T_s = 226^\circ\text{F}$ , obtain a relation for the temperature distribution, and determine the temperature at the centerline of the wire when steady operating conditions are reached.

**SOLUTION** This heat transfer problem is similar to the problem in Example 2-17, except that we need to obtain a relation for the variation of temperature within the wire with  $r$ . Differential equations are well suited for this purpose.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since there is no thermal symmetry about the centerline and no change in the axial direction. 3 Thermal conductivity is constant. 4 Heat generation in the wire is uniform.

**Properties** The thermal conductivity is given to be  $k = 7.8 \text{ Btu/h}\cdot\text{ft}\cdot\text{^\circ F}$ .

**Analysis** The differential equation which governs the variation of temperature in the wire is simply Eq. 2-27,

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{e}_{\text{gen}}}{k} = 0$$

FIGURE 2-58

Schematic for Example 2-17.

FIGURE 2-59

Schematic for Example 2-18.

**FIGURE 2-60**

The thermal symmetry condition at the centerline of a wire in which heat is generated uniformly.

This is a second-order linear ordinary differential equation, and thus its general solution contains two arbitrary constants. The determination of these constants requires the specification of two boundary conditions, which can be taken to be

$$T(r_o) = T_s = 226^{\circ}\text{F}$$

and

$$\frac{dT(0)}{dr} = 0$$

The first boundary condition simply states that the temperature of the outer surface of the wire is  $226^{\circ}\text{F}$ . The second boundary condition is the symmetry condition at the centerline, and states that the maximum temperature in the wire occurs at the centerline, and thus the slope of the temperature at  $r = 0$  must be zero (Fig. 2-60). This completes the mathematical formulation of the problem.

Although not immediately obvious, the differential equation is in a form that can be solved by direct integration. Multiplying both sides of the equation by  $r$  and rearranging, we obtain

$$\frac{d}{dr} \left( r \frac{dT}{dr} \right) = -\frac{\dot{e}_{\text{gen}}}{k} r$$

Integrating with respect to  $r$  gives

$$r \frac{dT}{dr} = -\frac{\dot{e}_{\text{gen}}}{k} \frac{r^2}{2} + C_1 \quad (a)$$

since the heat generation is constant, and the integral of a derivative of a function is the function itself. That is, integration removes a derivative. It is convenient at this point to apply the second boundary condition, since it is related to the first derivative of the temperature, by replacing all occurrences of  $r$  and  $dT/dr$  in Eq. (a) by zero. It yields

$$0 \times \frac{dT(0)}{dr} = -\frac{\dot{e}_{\text{gen}}}{2k} \times 0 + C_1 \rightarrow C_1 = 0$$

Thus  $C_1$  cancels from the solution. We now divide Eq. (a) by  $r$  to bring it to a readily integrable form,

$$\frac{dT}{dr} = -\frac{\dot{e}_{\text{gen}}}{2k} r$$

Again integrating with respect to  $r$  gives

$$T(r) = -\frac{\dot{e}_{\text{gen}}}{4k} r^2 + C_2 \quad (b)$$

We now apply the first boundary condition by replacing all occurrences of  $r$  by  $r_o$  and all occurrences of  $T$  by  $T_s$ . We get

$$T_s = -\frac{\dot{e}_{\text{gen}}}{4k} r_o^2 + C_2 \rightarrow C_2 = T_s + \frac{\dot{e}_{\text{gen}}}{4k} r_o^2$$

Substituting this  $C_2$  relation into Eq. (b) and rearranging give

$$T(r) = T_s + \frac{\dot{e}_{\text{gen}}}{4k} (r_o^2 - r^2) \quad (c)$$

which is the desired solution for the temperature distribution in the wire as a function of  $r$ . The temperature at the centerline ( $r = 0$ ) is obtained by replacing  $r$  in Eq. (c) by zero and substituting the known quantities,

$$T(0) = T_s + \frac{\dot{e}_{\text{gen}}}{4k} r_o^2 = 226^\circ\text{F} + \frac{2400 \text{ Btu/h}\cdot\text{in}^3}{4 \times (7.8 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F})} \left( \frac{12 \text{ in}}{1 \text{ ft}} \right) (0.2 \text{ in})^2 = 263^\circ\text{F}$$

**Discussion** The temperature of the centerline is  $37^\circ\text{F}$  above the temperature of the outer surface of the wire. Note that the expression above for the centerline temperature is identical to Eq. 2-71, which was obtained using an energy balance on a control volume.

### EXAMPLE 2-19 Heat Conduction in a Two-Layer Medium

Consider a long resistance wire of radius  $r_1 = 0.2 \text{ cm}$  and thermal conductivity  $k_{\text{wire}} = 15 \text{ W/m}\cdot\text{K}$  in which heat is generated uniformly as a result of resistance heating at a constant rate of  $\dot{e}_{\text{gen}} = 50 \text{ W/cm}^3$  (Fig. 2-61). The wire is embedded in a  $0.5\text{-cm-thick}$  layer of ceramic whose thermal conductivity is  $k_{\text{ceramic}} = 1.2 \text{ W/m}\cdot\text{K}$ . If the outer surface temperature of the ceramic layer is measured to be  $T_s = 45^\circ\text{C}$ , determine the temperatures at the center of the resistance wire and the interface of the wire and the ceramic layer under steady conditions.

**SOLUTION** The surface and interface temperatures of a resistance wire covered with a ceramic layer are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no change with time. 2 Heat transfer is one-dimensional since this two-layer heat transfer problem possesses symmetry about the centerline and involves no change in the axial direction, and thus  $T = T(r)$ . 3 Thermal conductivities are constant. 4 Heat generation in the wire is uniform.

**Properties** It is given that  $k_{\text{wire}} = 15 \text{ W/m}\cdot\text{K}$  and  $k_{\text{ceramic}} = 1.2 \text{ W/m}\cdot\text{K}$ .

**Analysis** Letting  $T_I$  denote the unknown interface temperature, the heat transfer problem in the wire can be formulated as

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT_{\text{wire}}}{dr} \right) + \frac{\dot{e}_{\text{gen}}}{k} = 0$$

with

$$T_{\text{wire}}(r_1) = T_I$$

$$\frac{dT_{\text{wire}}(0)}{dr} = 0$$

This problem was solved in Example 2-18, and its solution was determined to be

$$T_{\text{wire}}(r) = T_I + \frac{\dot{e}_{\text{gen}}}{4k_{\text{wire}}} (r_1^2 - r^2) \quad (a)$$

FIGURE 2-61

Schematic for Example 2-19.

Noting that the ceramic layer does not involve any heat generation and its outer surface temperature is specified, the heat conduction problem in that layer can be expressed as

$$\frac{d}{dr} \left( r \frac{dT_{\text{ceramic}}}{dr} \right) = 0$$

with

$$\begin{aligned} T_{\text{ceramic}}(r_1) &= T_I \\ T_{\text{ceramic}}(r_2) &= T_s = 45^\circ\text{C} \end{aligned}$$

This problem was solved in Example 2–16, and its solution was determined to be

$$T_{\text{ceramic}}(r) = \frac{\ln(r/r_1)}{\ln(r_2/r_1)} (T_s - T_I) + T_I \quad (b)$$

We have already utilized the first interface condition by setting the wire and ceramic layer temperatures equal to  $T_I$  at the interface  $r = r_1$ . The interface temperature  $T_I$  is determined from the second interface condition that the heat flux in the wire and the ceramic layer at  $r = r_1$  must be the same:

$$-k_{\text{wire}} \frac{dT_{\text{wire}}(r_1)}{dr} = -k_{\text{ceramic}} \frac{dT_{\text{ceramic}}(r_1)}{dr} \rightarrow \frac{\dot{e}_{\text{gen}} r_1}{2} = -k_{\text{ceramic}} \frac{T_s - T_I}{\ln(r_2/r_1)} \left( \frac{1}{r_1} \right)$$

Solving for  $T_I$  and substituting the given values, the interface temperature is determined to be

$$\begin{aligned} T_I &= \frac{\dot{e}_{\text{gen}} r_1^2}{2k_{\text{ceramic}}} \ln \frac{r_2}{r_1} + T_s \\ &= \frac{(50 \times 10^6 \text{ W/m}^3)(0.002 \text{ m})^2}{2(1.2 \text{ W/m}\cdot\text{K})} \ln \frac{0.007 \text{ m}}{0.002 \text{ m}} + 45^\circ\text{C} = 149.4^\circ\text{C} \end{aligned}$$

Knowing the interface temperature, the temperature at the centerline ( $r = 0$ ) is obtained by substituting the known quantities into Eq. (a),

$$T_{\text{wire}}(0) = T_I + \frac{\dot{e}_{\text{gen}} r_1^2}{4k_{\text{wire}}} = 149.4^\circ\text{C} + \frac{(50 \times 10^6 \text{ W/m}^3)(0.002 \text{ m})^2}{4 \times (15 \text{ W/m}\cdot\text{K})} = 152.7^\circ\text{C}$$

Thus the temperature of the centerline is slightly above the interface temperature.

**Discussion** This example demonstrates how steady one-dimensional heat conduction problems in composite media can be solved. We could also solve this problem by determining the heat flux at the interface by dividing the total heat generated in the wire by the surface area of the wire, and then using this value as the specified heat flux boundary condition for both the wire and the ceramic layer. This way the two problems are decoupled and can be solved separately.

**EXAMPLE 2–20****Heat Conduction in a Plane Wall with Heat Generation**

A large plane wall of thickness  $2L$  experiences a uniform heat generation (Fig. 2–62). Determine the expression for the variation of temperature within the wall, if (a)  $T_1 > T_2$  and (b)  $T_1 = T_2$ .

**SOLUTION** A large plane wall experiences a uniform heat generation. The expressions for the variation of temperature within the wall for  $T_1 > T_2$  and  $T_1 = T_2$  are to be determined.

**Assumptions** 1 Heat conduction is steady. 2 Heat conduction is one-dimensional. 3 Thermal conductivity is constant. 4 Heat generation is uniform.

**Analysis** We begin with the general heat conduction equation for rectangular coordinates,

$$\frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + \dot{e}_{\text{gen}} = \rho c \frac{\partial T}{\partial t}$$

For steady one-dimensional heat conduction and constant thermal conductivity, the general heat conduction equation is simplified to

$$\frac{d^2T}{dx^2} + \frac{\dot{e}_{\text{gen}}}{k} = 0$$

Integrating twice gives the general solution to this second order differential equation as

$$T(x) = -\frac{\dot{e}_{\text{gen}}}{2k}x^2 + C_1x + C_2$$

(a) For the case of asymmetrical boundary conditions with  $T_1 > T_2$ , applying the boundary conditions gives

$$x = -L: \quad T(-L) = T_1 = -\frac{\dot{e}_{\text{gen}}}{2k}L^2 - C_1L + C_2$$

$$x = L: \quad T(L) = T_2 = -\frac{\dot{e}_{\text{gen}}}{2k}L^2 + C_1L + C_2$$

Note that in this problem the coordinate system is placed at the middle of the plane wall ( $x = 0$ ) and  $x$  to the right of the centerline is considered positive and to the left negative. In analyzing plane wall problems with heat generation, this notation is usually adopted in order to better capture the effect of heat generation on the temperature profile. Solving for the constants  $C_1$  and  $C_2$  yields

$$C_1 = \frac{T_2 - T_1}{2L} \quad \text{and} \quad C_2 = \frac{\dot{e}_{\text{gen}}L^2}{2k} + \frac{T_1 + T_2}{2}$$

Substituting  $C_1$  and  $C_2$  expressions into the general solution, the variation of temperature within the wall is determined to be

$$T(x) = \frac{\dot{e}_{\text{gen}}L^2}{2k} \left( 1 - \frac{x^2}{L^2} \right) + \frac{T_2 - T_1}{2} \left( \frac{x}{L} \right) + \frac{T_1 + T_2}{2} \quad (\text{a})$$

**FIGURE 2–62**

Schematic for Example 2–20.

(b) For the case of symmetrical boundary conditions, substituting  $T_2 = T_1$  into the above equation gives

$$T(x) = \frac{\dot{e}_{\text{gen}} L^2}{2k} \left( 1 - \frac{x^2}{L^2} \right) + T_1 \quad (b)$$

**Discussion** Equation (a) shows that the variation of temperature within the wall for the case of asymmetrical boundary conditions with  $T_1 > T_2$  is not symmetric and the maximum temperature occurs to the left of the centerline. Note that Eq. (a) reduces to the temperature solution of Example 2-10 (Eq. 2-56) for heat conduction in a plane wall with no heat generation by setting  $\dot{e}_{\text{gen}} = 0$  and making the appropriate coordinate transformation. In the case of symmetrical boundary conditions ( $T_1 = T_2$ ), Eq. (b) shows that the variation of temperature within the wall is symmetric and the maximum temperature occurs at the centerline. This is comparable to the results shown in Example 2-17 for temperature variation in a cylindrical resistance heater.

FIGURE 2-63

Variation of the thermal conductivity of some solids with temperature.

## 2-7 • VARIABLE THERMAL CONDUCTIVITY, $k(T)$

You will recall from Chapter 1 that the thermal conductivity of a material, in general, varies with temperature (Fig. 2-63). However, this variation is mild for many materials in the range of practical interest and can be disregarded. In such cases, we can use an average value for the thermal conductivity and treat it as a constant, as we have been doing so far. This is also common practice for other temperature-dependent properties such as the density and specific heat.

When the variation of thermal conductivity with temperature in a specified temperature interval is large, however, it may be necessary to account for this variation to minimize the error. Accounting for the variation of the thermal conductivity with temperature, in general, complicates the analysis. But in the case of simple one-dimensional cases, we can obtain heat transfer relations in a straightforward manner.

When the variation of thermal conductivity with temperature  $k(T)$  is known, the average value of the thermal conductivity in the temperature range between  $T_1$  and  $T_2$  can be determined from

$$k_{\text{avg}} = \frac{\int_{T_1}^{T_2} k(T) dT}{T_2 - T_1} \quad (2-75)$$

This relation is based on the requirement that the rate of heat transfer through a medium with constant average thermal conductivity  $k_{\text{avg}}$  equals the rate of heat transfer through the same medium with variable conductivity  $k(T)$ . Note that in the case of constant thermal conductivity  $k(T) = k$ , Eq. 2-75 reduces to  $k_{\text{avg}} = k$ , as expected.

Then the rate of steady heat transfer through a plane wall, cylindrical layer, or spherical layer for the case of variable thermal conductivity can be determined

by replacing the constant thermal conductivity  $k$  in Eqs. 2–57, 2–59, and 2–61 by the  $k_{\text{avg}}$  expression (or value) from Eq. 2–75:

$$\dot{Q}_{\text{plane wall}} = k_{\text{avg}} A \frac{T_1 - T_2}{L} = \frac{A}{L} \int_{T_2}^{T_1} k(T) dT \quad (2-76)$$

$$\dot{Q}_{\text{cylinder}} = 2\pi k_{\text{avg}} L \frac{T_1 - T_2}{\ln(r_2/r_1)} = \frac{2\pi L}{\ln(r_2/r_1)} \int_{T_2}^{T_1} k(T) dT \quad (2-77)$$

$$\dot{Q}_{\text{sphere}} = 4\pi k_{\text{avg}} r_1 r_2 \frac{T_1 - T_2}{r_2 - r_1} = \frac{4\pi r_1 r_2}{r_2 - r_1} \int_{T_2}^{T_1} k(T) dT \quad (2-78)$$

The variation in thermal conductivity of a material with temperature in the temperature range of interest can often be approximated as a linear function and expressed as

$$k(T) = k_0(1 + \beta T) \quad (2-79)$$

where  $\beta$  is called the **temperature coefficient of thermal conductivity**. The *average* value of thermal conductivity in the temperature range  $T_1$  to  $T_2$  in this case can be determined from

$$k_{\text{avg}} = \frac{\int_{T_1}^{T_2} k_0(1 + \beta T) dT}{T_2 - T_1} = k_0 \left( 1 + \beta \frac{T_2 + T_1}{2} \right) = k(T_{\text{avg}}) \quad (2-80)$$

Note that the *average thermal conductivity* in this case is equal to the thermal conductivity value at the *average temperature*.

We have mentioned earlier that in a plane wall the temperature varies linearly during steady one-dimensional heat conduction when the thermal conductivity is constant. But this is no longer the case when the thermal conductivity changes with temperature, even linearly, as shown in Fig. 2–64.

### EXAMPLE 2–21 Variation of Temperature in a Wall with $k(T)$

Consider a plane wall of thickness  $L$  whose thermal conductivity varies linearly in a specified temperature range as  $k(T) = k_0(1 + \beta T)$  where  $k_0$  and  $\beta$  are constants. The wall surface at  $x = 0$  is maintained at a constant temperature of  $T_1$  while the surface at  $x = L$  is maintained at  $T_2$ , as shown in Fig. 2–65. Assuming steady one-dimensional heat transfer, obtain a relation for (a) the heat transfer rate through the wall and (b) the temperature distribution  $T(x)$  in the wall.

**SOLUTION** A plate with variable conductivity is subjected to specified temperatures on both sides. The variation of temperature and the rate of heat transfer are to be determined.

**Assumptions** 1 Heat transfer is given to be steady and one-dimensional. 2 Thermal conductivity varies linearly. 3 There is no heat generation.

**Properties** The thermal conductivity is given to be  $k(T) = k_0(1 + \beta T)$ .

**Analysis** (a) The rate of heat transfer through the wall can be determined from

$$\dot{Q} = k_{\text{avg}} A \frac{T_1 - T_2}{L}$$

FIGURE 2–64

The variation of temperature in a plane wall during steady one-dimensional heat conduction for the cases of constant and variable thermal conductivity.

FIGURE 2–65

Schematic for Example 2–21.

where  $A$  is the heat conduction area of the wall and

$$k_{\text{avg}} = k(T_{\text{avg}}) = k_0 \left( 1 + \beta \frac{T_2 + T_1}{2} \right)$$

is the average thermal conductivity (Eq. 2-80).

(b) To determine the temperature distribution in the wall, we begin with Fourier's law of heat conduction, expressed as

$$\dot{Q} = -k(T) A \frac{dT}{dx}$$

where the rate of conduction heat transfer  $\dot{Q}$  and the area  $A$  are constant. Separating variables and integrating from  $x = 0$  where  $T(0) = T_1$  to any  $x$  where  $T(x) = T$ , we get

$$\int_0^x \dot{Q} dx = -A \int_{T_1}^T k(T) dT$$

Substituting  $k(T) = k_0(1 + \beta T)$  and performing the integrations we obtain

$$\dot{Q}x = -Ak_0[(T - T_1) + \beta(T^2 - T_1^2)/2]$$

Substituting the  $\dot{Q}$  expression from part (a) and rearranging give

$$T^2 + \frac{2}{\beta} T + \frac{2k_{\text{avg}}}{\beta k_0} \frac{x}{L} (T_1 - T_2) - T_1^2 - \frac{2}{\beta} T_1 = 0$$

which is a *quadratic* equation in the unknown temperature  $T$ . Using the quadratic formula, the temperature distribution  $T(x)$  in the wall is determined to be

$$T(x) = -\frac{1}{\beta} \pm \sqrt{\frac{1}{\beta^2} - \frac{2k_{\text{avg}}}{\beta k_0} \frac{x}{L} (T_1 - T_2) + T_1^2 + \frac{2}{\beta} T_1}$$

**Discussion** The proper sign of the square root term (+ or -) is determined from the requirement that the temperature at any point within the medium must remain between  $T_1$  and  $T_2$ . This result explains why the temperature distribution in a plane wall is no longer a straight line when the thermal conductivity varies with temperature.

FIGURE 2-66

Schematic for Example 2-22.

### EXAMPLE 2-22 Heat Conduction through a Wall with $k(T)$

Consider a 2-m-high and 0.7-m-wide bronze plate whose thickness is 0.1 m. One side of the plate is maintained at a constant temperature of 600 K while the other side is maintained at 400 K, as shown in Fig. 2-66. The thermal conductivity of the bronze plate can be assumed to vary linearly in that temperature range as  $k(T) = k_0(1 + \beta T)$  where  $k_0 = 38 \text{ W/m}\cdot\text{K}$  and  $\beta = 9.21 \times 10^{-4} \text{ K}^{-1}$ . Disregarding the edge effects and assuming steady one-dimensional heat transfer, determine the rate of heat conduction through the plate.

**SOLUTION** A plate with variable conductivity is subjected to specified temperatures on both sides. The rate of heat transfer is to be determined.

**Assumptions** 1 Heat transfer is given to be steady and one-dimensional. 2 Thermal conductivity varies linearly. 3 There is no heat generation.

**Properties** The thermal conductivity is given to be  $k(T) = k_0(1 + \beta T)$ .

**Analysis** The average thermal conductivity of the medium in this case is simply the value at the average temperature and is determined from

$$\begin{aligned}k_{\text{avg}} &= k(T_{\text{avg}}) = k_0 \left( 1 + \beta \frac{T_2 + T_1}{2} \right) \\&= (38 \text{ W/m}\cdot\text{K}) \left[ 1 + (9.21 \times 10^{-4} \text{ K}^{-1}) \frac{(600 + 400) \text{ K}}{2} \right] \\&= 55.5 \text{ W/m}\cdot\text{K}\end{aligned}$$

Then the rate of heat conduction through the plate can be determined from Eq. 2–76 to be

$$\begin{aligned}\dot{Q} &= k_{\text{avg}} A \frac{T_1 - T_2}{L} \\&= (55.5 \text{ W/m}\cdot\text{K})(2 \text{ m} \times 0.7 \text{ m}) \frac{(600 - 400) \text{ K}}{0.1 \text{ m}} = 155 \text{ kW}\end{aligned}$$

**Discussion** We would have obtained the same result by substituting the given  $k(T)$  relation into the second part of Eq. 2–76 and performing the indicated integration.

## TOPIC OF SPECIAL INTEREST\*

### A Brief Review of Differential Equations

As we mentioned in Chapter 1, the description of most scientific problems involves relations that involve changes in some key variables with respect to each other. Usually the smaller the increment chosen in the changing variables, the more general and accurate the description. In the limiting case of infinitesimal or differential changes in variables, we obtain *differential equations*, which provide precise mathematical formulations for the physical principles and laws by representing the rates of change as *derivatives*. Therefore, differential equations are used to investigate a wide variety of problems in sciences and engineering, including heat transfer.

Differential equations arise when relevant *physical laws* and *principles* are applied to a problem by considering infinitesimal changes in the variables of interest. Therefore, obtaining the governing differential equation for a specific problem requires an adequate knowledge of the nature of the problem, the variables involved, appropriate simplifying assumptions, and the applicable physical laws and principles involved, as well as a careful analysis.

An equation, in general, may involve one or more variables. As the name implies, a **variable** is a quantity that may assume various values during a study. A quantity whose value is fixed during a study is called a **constant**. Constants are usually denoted by the earlier letters of the alphabet such as  $a$ ,  $b$ ,  $c$ , and  $d$ , whereas variables are usually denoted by the later ones such

---

\*This section can be skipped without a loss in continuity.

FIGURE 2-67

The derivative of a function at a point represents the slope of the tangent line of the function at that point.

as  $t$ ,  $x$ ,  $y$ , and  $z$ . A variable whose value can be changed arbitrarily is called an **independent variable** (or argument). A variable whose value depends on the value of other variables and thus cannot be varied independently is called a **dependent variable** (or a function).

A dependent variable  $y$  that depends on a variable  $x$  is usually denoted as  $y(x)$  for clarity. However, this notation becomes very inconvenient and cumbersome when  $y$  is repeated several times in an expression. In such cases it is desirable to denote  $y(x)$  simply as  $y$  when it is clear that  $y$  is a function of  $x$ . This shortcut in notation improves the appearance and the readability of the equations. The value of  $y$  at a fixed number  $a$  is denoted by  $y(a)$ .

The **derivative** of a function  $y(x)$  at a point is equivalent to the *slope* of the tangent line to the graph of the function at that point and is defined as (Fig. 2-67)

$$y'(x) = \frac{dy(x)}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{y(x + \Delta x) - y(x)}{\Delta x} \quad (2-81)$$

Here  $\Delta x$  represents a (small) change in the independent variable  $x$  and is called an *increment* of  $x$ . The corresponding change in the function  $y$  is called an increment of  $y$  and is denoted by  $\Delta y$ . Therefore, the derivative of a function can be viewed as the ratio of the increment  $\Delta y$  of the function to the increment  $\Delta x$  of the independent variable for very small  $\Delta x$ . Note that  $\Delta y$  and thus  $y'(x)$  are zero if the function  $y$  does not change with  $x$ .

Most problems encountered in practice involve quantities that change with time  $t$ , and their first derivatives with respect to time represent the rate of change of those quantities with time. For example, if  $N(t)$  denotes the population of a bacteria colony at time  $t$ , then the first derivative  $N' = dN/dt$  represents the rate of change of the population, which is the amount the population increases or decreases per unit time.

The derivative of the first derivative of a function  $y$  is called the *second derivative* of  $y$ , and is denoted by  $y''$  or  $d^2y/dx^2$ . In general, the derivative of the  $(n - 1)$ st derivative of  $y$  is called the *n*th derivative of  $y$  and is denoted by  $y^{(n)}$  or  $d^n y/dx^n$ . Here,  $n$  is a positive integer and is called the *order* of the derivative. The order  $n$  should not be confused with the *degree* of a derivative. For example,  $y'''$  is the third-order derivative of  $y$ , but  $(y')^3$  is the third degree of the first derivative of  $y$ . Note that the first derivative of a function represents the *slope* or the *rate of change* of the function with the independent variable, and the second derivative represents the *rate of change of the slope* of the function with the independent variable.

When a function  $y$  depends on two or more independent variables such as  $x$  and  $t$ , it is sometimes of interest to examine the dependence of the function on one of the variables only. This is done by taking the derivative of the function with respect to that variable while holding the other variables constant. Such derivatives are called **partial derivatives**. The first partial derivatives of the function  $y(x, t)$  with respect to  $x$  and  $t$  are defined as (Fig. 2-68)

$$\frac{\partial y}{\partial x} = \lim_{\Delta x \rightarrow 0} \frac{y(x + \Delta x, t) - y(x, t)}{\Delta x} \quad (2-82)$$

FIGURE 2-68

Graphical representation of partial derivative  $\partial z/\partial x$ .

$$\frac{\partial y}{\partial t} = \lim_{\Delta t \rightarrow 0} \frac{y(x, t + \Delta t) - y(x, t)}{\Delta t} \quad (2-83)$$

Note that when finding  $\partial y / \partial x$  we treat  $t$  as a constant and differentiate  $y$  with respect to  $x$ . Likewise, when finding  $\partial y / \partial t$  we treat  $x$  as a constant and differentiate  $y$  with respect to  $t$ .

**Integration** can be viewed as the inverse process of differentiation. Integration is commonly used in solving differential equations since solving a differential equation is essentially a process of removing the derivatives from the equation. Differentiation is the process of finding  $y'(x)$  when a function  $y(x)$  is given, whereas integration is the process of finding the function  $y(x)$  when its derivative  $y'(x)$  is given. The integral of this derivative is expressed as

$$\int y'(x) dx = \int dy = y(x) + C \quad (2-84)$$

since  $y'(x)dx = dy$  and the integral of the differential of a function is the function itself (plus a constant, of course). In Eq. 2-84,  $x$  is the integration variable and  $C$  is an arbitrary constant called the **integration constant**.

The derivative of  $y(x) + C$  is  $y'(x)$  no matter what the value of the constant  $C$  is. Therefore, two functions that differ by a constant have the same derivative, and we always add a constant  $C$  during integration to recover this constant that is lost during differentiation. The integral in Eq. 2-84 is called an **indefinite integral** since the value of the arbitrary constant  $C$  is indefinite. The described procedure can be extended to higher-order derivatives (Fig. 2-69). For example,

$$\int y''(x) dx = y'(x) + C \quad (2-85)$$

This can be proved by defining a new variable  $u(x) = y'(x)$ , differentiating it to obtain  $u'(x) = y''(x)$ , and then applying Eq. 2-84. Therefore, the order of a derivative decreases by one each time it is integrated.

## Classification of Differential Equations

A differential equation that involves only ordinary derivatives is called an **ordinary differential equation**, and a differential equation that involves partial derivatives is called a **partial differential equation**. Then it follows that problems that involve a single independent variable result in ordinary differential equations, and problems that involve two or more independent variables result in partial differential equations. A differential equation may involve several derivatives of various orders of an unknown function. The order of the highest derivative in a differential equation is the order of the equation. For example, the order of  $y''' + (y'')^4 = 7x^5$  is 3 since it contains no fourth or higher order derivatives.

You will remember from algebra that the equation  $3x - 5 = 0$  is much easier to solve than the equation  $x^4 + 3x - 5 = 0$  because the first equation is linear whereas the second one is nonlinear. This is also true for differential equations. Therefore, before we start solving a differential

**FIGURE 2-69**

Some indefinite integrals that involve derivatives.

FIGURE 2-70

A differential equation that is (a) nonlinear and (b) linear. When checking for linearity, we examine the dependent variable only.

FIGURE 2-71

A differential equation with (a) constant coefficients and (b) variable coefficients.

equation, we usually check for linearity. A differential equation is said to be **linear** if the dependent variable and all of its derivatives are of the first degree and their coefficients depend on the independent variable only. In other words, a differential equation is linear if it can be written in a form that does not involve (1) any powers of the dependent variable or its derivatives such as  $y^3$  or  $(y')^2$ , (2) any products of the dependent variable or its derivatives such as  $yy'$  or  $y'y'''$ , and (3) any other nonlinear functions of the dependent variable such as  $\sin y$  or  $e^y$ . If any of these conditions apply, it is **nonlinear** (Fig. 2-70).

A linear differential equation, however, may contain (1) powers or nonlinear functions of the independent variable, such as  $x^2$  and  $\cos x$  and (2) products of the dependent variable (or its derivatives) and functions of the independent variable, such as  $x^3y'$ ,  $x^2y$ , and  $e^{-2x}y''$ . A linear differential equation of order  $n$  can be expressed in the most general form as

$$y^{(n)} + f_1(x)y^{(n-1)} + \cdots + f_{n-1}(x)y' + f_n(x)y = R(x) \quad (2-86)$$

A differential equation that cannot be put into this form is nonlinear. A linear differential equation in  $y$  is said to be **homogeneous** as well if  $R(x) = 0$ . Otherwise, it is nonhomogeneous. That is, each term in a linear homogeneous equation contains the dependent variable or one of its derivatives after the equation is cleared of any common factors. The term  $R(x)$  is called the *nonhomogeneous term*.

Differential equations are also classified by the nature of the coefficients of the dependent variable and its derivatives. A differential equation is said to have **constant coefficients** if the coefficients of all the terms that involve the dependent variable or its derivatives are constants. If, after clearing any common factors, any of the terms with the dependent variable or its derivatives involve the independent variable as a coefficient, that equation is said to have **variable coefficients** (Fig. 2-71). Differential equations with constant coefficients are usually much easier to solve than those with variable coefficients.

## Solutions of Differential Equations

Solving a differential equation can be as easy as performing one or more integrations; but such simple differential equations are usually the exception rather than the rule. There is no single general solution method applicable to all differential equations. There are different solution techniques, each being applicable to different classes of differential equations. Sometimes solving a differential equation requires the use of two or more techniques as well as ingenuity and mastery of solution methods. Some differential equations can be solved only by using some very clever tricks. Some cannot be solved analytically at all.

In algebra, we usually seek discrete values that satisfy an algebraic equation such as  $x^2 - 7x - 10 = 0$ . When dealing with differential equations, however, we seek functions that satisfy the equation in a specified interval. For example, the algebraic equation  $x^2 - 7x - 10 = 0$  is satisfied by two

numbers only: 2 and 5. But the differential equation  $y' - 7y = 0$  is satisfied by the function  $e^{7x}$  for any value of  $x$  (Fig. 2–72).

Consider the algebraic equation  $x^3 - 6x^2 + 11x - 6 = 0$ . Obviously,  $x = 1$  satisfies this equation, and thus it is a solution. However, it is not the only solution of this equation. We can easily show by direct substitution that  $x = 2$  and  $x = 3$  also satisfy this equation, and thus they are solutions as well. But there are no other solutions to this equation. Therefore, we say that the set 1, 2, and 3 forms the complete solution to this algebraic equation.

The same line of reasoning also applies to differential equations. Typically, differential equations have multiple solutions that contain at least one arbitrary constant. Any function that satisfies the differential equation on an interval is called a *solution* of that differential equation in that interval. A solution that involves one or more arbitrary constants represents a family of functions that satisfy the differential equation and is called a **general solution** of that equation. Not surprisingly, a differential equation may have more than one general solution. A general solution is usually referred to as the **general solution** or the **complete solution** if every solution of the equation can be obtained from it as a special case. A solution that can be obtained from a general solution by assigning particular values to the arbitrary constants is called a **specific solution**.

You will recall from algebra that a number is a solution of an algebraic equation if it satisfies the equation. For example, 2 is a solution of the equation  $x^3 - 8 = 0$  because the substitution of 2 for  $x$  yields identically zero. Likewise, a function is a solution of a differential equation if that function satisfies the differential equation. In other words, a solution function yields identity when substituted into the differential equation. For example, it can be shown by direct substitution that the function  $3e^{-2x}$  is a solution of  $y'' - 4y = 0$  (Fig. 2–73).

## General Solution to Selected Differential Equations

This section provides general solution to the differential equations presented in Chapters 2 and 3. First the general solution to the one-dimensional steady-state, constant properties heat conduction equations with and without heat generation in three coordinate systems (rectangular, cylindrical, and spherical) presented in Chapter 2 are listed, followed by the general solution to the fin and the bioheat transfer equations of Chapter 3.

- 1-D steady state heat conduction equation with constant heat generation—rectangular coordinates (Eq. 2–15)

$$\frac{d^2y}{dx^2} + S = 0$$

$$\text{Solution: } y(x) = C_1x + C_2 - \frac{1}{2}Sx^2$$

(a) An algebraic equation:

$$y^2 - 7y - 10 = 0$$

*Solution:*  $y = 2$  and  $y = 5$

(b) A differential equation:

$$y' - 7y = 0$$

*Solution:*  $y = e^{7x}$

FIGURE 2–72

Unlike those of algebraic equations, the solutions of differential equations are typically functions instead of discrete values.

$$\text{Function: } f = 3e^{-2x}$$

$$\text{Differential equation: } y'' - 4y = 0$$

Derivatives of  $f$ :

$$f' = -6e^{-2x}$$

$$f'' = 12e^{-2x}$$

Substituting into  $y'' - 4y = 0$ :

$$f'' - 4f \stackrel{?}{=} 0$$

$$12e^{-2x} - 4 \times 3e^{-2x} \stackrel{?}{=} 0$$

$$0 = 0$$

Therefore, the function  $3e^{-2x}$  is a solution of the differential equation  $y'' - 4y = 0$ .

FIGURE 2–73

Verifying that a given function is a solution of a differential equation.

- 1-D steady state heat conduction equation without heat generation—rectangular coordinates (Eq. 2-17)

$$\frac{d^2y}{dx^2} = 0$$

Solution:  $y(x) = C_1x + C_2$

- 1-D steady state heat conduction equation with constant heat generation—cylindrical coordinates (Eq. 2-27)

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dy}{dr} \right) + S = 0$$

Solution:  $y(r) = C_1 \ln r + C_2 - \frac{1}{4} S r^2$

- 1-D steady state heat conduction equation without heat generation—cylindrical coordinates (Eq. 2-29)

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dy}{dr} \right) = 0$$

Solution:  $y(r) = C_1 \ln r + C_2$

- 1-D steady state heat conduction equation with constant heat generation—spherical coordinates (Eq. 2-32)

$$\frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{dy}{dr} \right) + S = 0$$

Solution:  $y(r) = \frac{C_1}{r} + C_2 - \frac{1}{6} S r^2$

- 1-D steady state heat conduction equation without heat generation—spherical coordinates (Eq. 2-34)

$$\frac{d}{dr} \left( r^2 \frac{dy}{dr} \right) = 0$$

Solution:  $y(r) = \frac{C_1}{r} + C_2$

- 1-D steady-state fin or bioheat transfer equations for uniform cross section with constant coefficients—rectangular coordinates (Eq. 3-56 or Eq. 3-88)

$$\frac{d^2y}{dx^2} - \lambda^2 y = 0$$

Solution:  $y(x) = C_1 e^{+\lambda x} + C_2 e^{-\lambda x}$

- Modified Bessel equation of order zero with constant coefficients (bioheat transfer equation)—cylindrical coordinates (Eq. 3-90)

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dy}{dr} \right) - B^2 y = 0$$

Solution:  $y(r) = C_1 I_0(Br) + C_2 K_0(Br)$

where  $I_0$  and  $K_0$  are modified, zero-order Bessel functions of the first and second kinds, respectively. The values of  $I_0$  and  $K_0$  are given in Table 3-4.

## SUMMARY

In this chapter we have studied the heat conduction equation and its solutions. Heat conduction in a medium is said to be *steady* when the temperature does not vary with time and *unsteady* or *transient* when it does. Heat conduction in a medium is said to be *one-dimensional* when conduction is significant in one dimension only and negligible in the other two dimensions. It is said to be *two-dimensional* when conduction in the third dimension is negligible and *three-dimensional* when conduction in all dimensions is significant. In heat transfer analysis, the conversion of electrical, chemical, or nuclear energy into heat (or thermal) energy is characterized as *heat generation*.

The heat conduction equation can be derived by performing an energy balance on a differential volume element. The one-dimensional heat conduction equation in rectangular, cylindrical, and spherical coordinate systems for the case of constant thermal conductivities are expressed as

$$\begin{aligned} \frac{\partial^2 T}{\partial x^2} + \frac{\dot{e}_{\text{gen}}}{k} &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \\ \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) + \frac{\dot{e}_{\text{gen}}}{k} &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \\ \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) + \frac{\dot{e}_{\text{gen}}}{k} &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \end{aligned}$$

where the property  $\alpha = k/\rho c$  is the *thermal diffusivity* of the material.

The solution of a heat conduction problem depends on the conditions at the surfaces, and the mathematical expressions for the thermal conditions at the boundaries are called the *boundary conditions*. The solution of transient heat conduction problems also depends on the condition of the medium at the beginning of the heat conduction process. Such a condition, which is usually specified at time  $t = 0$ , is called the *initial condition*, which is a mathematical expression for the temperature distribution of the medium initially. Complete mathematical description of a heat conduction problem requires the specification of two boundary conditions for each dimension along which heat conduction is significant, and an initial condition when the problem is transient. The most common boundary conditions are the *specified temperature*, *specified heat flux*, *convection*, and *radiation* boundary conditions. A boundary surface, in general, may involve specified heat flux, convection, and radiation at the same time.

For steady one-dimensional heat transfer through a plate of thickness  $L$ , the various types of boundary conditions at the surfaces at  $x = 0$  and  $x = L$  can be expressed as

*Specified temperature:*

$$T(0) = T_1 \quad \text{and} \quad T(L) = T_2$$

where  $T_1$  and  $T_2$  are the specified temperatures at surfaces at  $x = 0$  and  $x = L$ .

*Specified heat flux:*

$$-k \frac{dT(0)}{dx} = \dot{q}_0 \quad \text{and} \quad -k \frac{dT(L)}{dx} = \dot{q}_L$$

where  $\dot{q}_0$  and  $\dot{q}_L$  are the specified heat fluxes at surfaces at  $x = 0$  and  $x = L$ .

*Insulation or thermal symmetry:*

$$\frac{dT(0)}{dx} = 0 \quad \text{and} \quad \frac{dT(L)}{dx} = 0$$

*Convection:*

$$-k \frac{dT(0)}{dx} = h_1[T_{\infty 1} - T(0)] \quad \text{and} \quad -k \frac{dT(L)}{dx} = h_2[T(L) - T_{\infty 2}]$$

where  $h_1$  and  $h_2$  are the convection heat transfer coefficients and  $T_{\infty 1}$  and  $T_{\infty 2}$  are the temperatures of the surrounding media on the two sides of the plate.

*Radiation:*

$$-k \frac{dT(0)}{dx} = \varepsilon_1 \sigma [T_{\text{surr}, 1}^4 - T(0)^4] \quad \text{and}$$

$$-k \frac{dT(L)}{dx} = \varepsilon_2 \sigma [T(L)^4 - T_{\text{surr}, 2}^4]$$

where  $\varepsilon_1$  and  $\varepsilon_2$  are the emissivities of the boundary surfaces,  $\sigma = 5.67 \times 10^{-8} \text{ W/m}^2\text{K}^4$  is the Stefan–Boltzmann constant, and  $T_{\text{surr}, 1}$  and  $T_{\text{surr}, 2}$  are the average temperatures of the surfaces surrounding the two sides of the plate. In radiation calculations, the temperatures must be in K or R.

*Interface of two bodies A and B in perfect contact at  $x = x_0$ :*

$$T_A(x_0) = T_B(x_0) \quad \text{and} \quad -k_A \frac{dT_A(x_0)}{dx} = -k_B \frac{dT_B(x_0)}{dx}$$

where  $k_A$  and  $k_B$  are the thermal conductivities of the layers A and B.

Heat generation is usually expressed *per unit volume* of the medium and is denoted by  $\dot{e}_{\text{gen}}$ , whose unit is  $\text{W/m}^3$ . Under steady conditions, the surface temperature  $T_s$  of a plane wall of thickness  $2L$ , a cylinder of outer radius  $r_o$ , and a sphere of radius  $r_o$  in which heat is generated at a constant rate of

$\dot{e}_{\text{gen}}$  per unit volume in a surrounding medium at  $T_\infty$  can be expressed as

$$T_{s, \text{plane wall}} = T_\infty + \frac{\dot{e}_{\text{gen}} L}{h}$$

$$T_{s, \text{cylinder}} = T_\infty + \frac{\dot{e}_{\text{gen}} r_o}{2h}$$

$$T_{s, \text{sphere}} = T_\infty + \frac{\dot{e}_{\text{gen}} r_o}{3h}$$

where  $h$  is the convection heat transfer coefficient. The maximum temperature rise between the surface and the midsection of a medium is given by

$$\Delta T_{\max, \text{plane wall}} = \frac{\dot{e}_{\text{gen}} L^2}{2k}$$

$$\Delta T_{\max, \text{cylinder}} = \frac{\dot{e}_{\text{gen}} r_o^2}{4k}$$

$$\Delta T_{\max, \text{sphere}} = \frac{\dot{e}_{\text{gen}} r_o^2}{6k}$$

When the variation of thermal conductivity with temperature  $k(T)$  is known, the average value of the thermal conductivity in the temperature range between  $T_1$  and  $T_2$  can be determined from

$$k_{\text{avg}} = \frac{\int_{T_1}^{T_2} k(T) dT}{T_2 - T_1}$$

Then the rate of steady heat transfer through a plane wall, cylindrical layer, or spherical layer can be expressed as

$$\dot{Q}_{\text{plane wall}} = k_{\text{avg}} A \frac{T_1 - T_2}{L} = \frac{A}{L} \int_{T_1}^{T_2} k(T) dT$$

$$\dot{Q}_{\text{cylinder}} = 2\pi k_{\text{avg}} L \frac{T_1 - T_2}{\ln(r_2/r_1)} = \frac{2\pi L}{\ln(r_2/r_1)} \int_{T_1}^{T_2} k(T) dT$$

$$\dot{Q}_{\text{sphere}} = 4\pi k_{\text{avg}} r_1 r_2 \frac{T_1 - T_2}{r_2 - r_1} = \frac{4\pi r_1 r_2}{r_2 - r_1} \int_{T_1}^{T_2} k(T) dT$$

The variation of thermal conductivity of a material with temperature can often be approximated as a linear function and expressed as

$$k(T) = k_0(1 + \beta T)$$

where  $\beta$  is called the *temperature coefficient of thermal conductivity*.

## PROBLEMS\*

### Introduction

**2-1C** How does transient heat transfer differ from steady heat transfer? How does one-dimensional heat transfer differ from two-dimensional heat transfer?

**2-2C** Is heat transfer a scalar or vector quantity? Explain. Answer the same question for temperature.

**2-3C** Does a heat flux vector at a point  $P$  on an isothermal surface of a medium have to be perpendicular to the surface at that point? Explain.

**2-4C** From a heat transfer point of view, what is the difference between isotropic and anisotropic materials?

**2-5C** What is heat generation in a solid? Give examples.

**2-6C** Heat generation is also referred to as energy generation or thermal energy generation. What do you think of these phrases?

**2-7C** In order to size the compressor of a new refrigerator, it is desired to determine the rate of heat transfer from the kitchen air into the refrigerated space through the walls, door, and the top and bottom section of the refrigerator. In your analysis, would you treat this as a transient or steady-state heat transfer problem? Also, would you consider the heat transfer to be one-dimensional or multidimensional? Explain.

**2-8C** In order to determine the size of the heating element of a new oven, it is desired to determine the rate of heat loss through the walls, door, and the top and bottom section of the oven. In your analysis, would you consider this to be a steady

\*Problems designated by a "C" are concept questions, and students are encouraged to answer them all. Problems designated by an "E" are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and the complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature, and are intended to be solved with an equation solver such as EES. Problems with the icon are Prevention through Design problems.

or transient heat transfer problem? Also, would you consider the heat transfer to be one-dimensional or multidimensional? Explain.

**2-9C** Consider a round potato being baked in an oven. Would you model the heat transfer to the potato as one-, two-, or three-dimensional? Would the heat transfer be steady or transient? Also, which coordinate system would you use to solve this problem, and where would you place the origin? Explain.

**2-10C** Consider an egg being cooked in boiling water in a pan. Would you model the heat transfer to the egg as one-, two-, or three-dimensional? Would the heat transfer be steady or transient? Also, which coordinate system would you use to solve this problem, and where would you place the origin? Explain.

**2-11C** Consider a hot dog being cooked in boiling water in a pan. Would you model the heat transfer to the hot dog as one-, two-, or three-dimensional? Would the heat transfer be steady or transient? Also, which coordinate system would you use to solve this problem, and where would you place the origin? Explain.

FIGURE P2-11C

**2-12C** Consider the cooking process of a roast beef in an oven. Would you consider this to be a steady or transient heat transfer problem? Also, would you consider this to be one-, two-, or three-dimensional? Explain.

**2-13C** Consider heat loss from a 200-L cylindrical hot water tank in a house to the surrounding medium. Would you consider this to be a steady or transient heat transfer problem? Also, would you consider this heat transfer problem to be one-, two-, or three-dimensional? Explain.

**2-14C** Consider a cold canned drink left on a dinner table. Would you model the heat transfer to the drink as one-, two-, or three-dimensional? Would the heat transfer be steady or transient? Also, which coordinate system would you use to analyze this heat transfer problem, and where would you place the origin? Explain.

**2-15** Heat flux meters use a very sensitive device known as a thermopile to measure the temperature difference across a thin, heat conducting film made of kapton ( $k = 0.345 \text{ W/m}\cdot\text{K}$ ). If the thermopile can detect temperature differences of  $0.1^\circ\text{C}$  or more and the film thickness is 2 mm, what is the minimum heat flux this meter can detect? *Answer:  $17.3 \text{ W/m}^2$*

**2-16** Consider a large 3-cm-thick stainless steel plate in which heat is generated uniformly at a rate of  $5 \times 10^6 \text{ W/m}^3$ . Assuming the plate is losing heat from both sides, determine the heat flux on the surface of the plate during steady operation. *Answer:  $75 \text{ kW/m}^2$*

**2-17** In a nuclear reactor, heat is generated uniformly in the 5-cm-diameter cylindrical uranium rods at a rate of  $2 \times 10^8 \text{ W/m}^3$ . If the length of the rods is 1 m, determine the rate of heat generation in each rod. *Answer: 393 kW*

**2-18** In a solar pond, the absorption of solar energy can be modeled as heat generation and can be approximated by  $\dot{e}_{\text{gen}} = \dot{e}_0 e^{-bx}$ , where  $\dot{e}_0$  is the rate of heat absorption at the top surface per unit volume and  $b$  is a constant. Obtain a relation for the total rate of heat generation in a water layer of surface area  $A$  and thickness  $L$  at the top of the pond.

FIGURE P2-18

**2-19E** The resistance wire of an 800-W iron is 15 in long and has a diameter of  $D = 0.08 \text{ in}$ . Determine the rate of heat generation in the wire per unit volume, in  $\text{Btu/h}\cdot\text{ft}^3$ , and the heat flux on the outer surface of the wire, in  $\text{Btu/h}\cdot\text{ft}^2$ , as a result of this heat generation.

FIGURE P2-19E

### Heat Conduction Equation

**2-20C** Write down the one-dimensional transient heat conduction equation for a plane wall with constant thermal conductivity and heat generation in its simplest form, and indicate what each variable represents.

**2-21C** Write down the one-dimensional transient heat conduction equation for a long cylinder with constant thermal conductivity and heat generation, and indicate what each variable represents.

**2-22** Starting with an energy balance on a rectangular volume element, derive the one-dimensional transient heat conduction

equation for a plane wall with constant thermal conductivity and no heat generation.

**2-23** Starting with an energy balance on a cylindrical shell volume element, derive the steady one-dimensional heat conduction equation for a long cylinder with constant thermal conductivity in which heat is generated at a rate of  $\dot{e}_{\text{gen}}$ .

FIGURE P2-23

**2-24** Starting with an energy balance on a spherical shell volume element, derive the one-dimensional transient heat conduction equation for a sphere with constant thermal conductivity and no heat generation.

FIGURE P2-24

**2-25** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-26** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-27** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{1}{r} \frac{d}{dr} \left( rk \frac{dT}{dr} \right) + \dot{e}_{\text{gen}} = 0$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-28** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{1}{r} \frac{\partial}{\partial r} \left( kr \frac{\partial T}{\partial r} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + \dot{e}_{\text{gen}} = 0$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-29** Consider a medium in which the heat conduction equation is given in its simplest form as

$$r \frac{d^2 T}{dr^2} + 2 \frac{dT}{dr} = 0$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-30** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2-31** Consider a medium in which the heat conduction equation is given in its simplest form as

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) + \frac{1}{r^2 \sin^2 \theta} \frac{\partial^2 T}{\partial \phi^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?

**2–32** Starting with an energy balance on a volume element, derive the two-dimensional transient heat conduction equation in rectangular coordinates for  $T(x, y, t)$  for the case of constant thermal conductivity and no heat generation.

**2–33** Starting with an energy balance on a ring-shaped volume element, derive the two-dimensional steady heat conduction equation in cylindrical coordinates for  $T(r, z)$  for the case of constant thermal conductivity and no heat generation.

FIGURE P2–33

**2–34** Starting with an energy balance on a disk volume element, derive the one-dimensional transient heat conduction equation for  $T(z, t)$  in a cylinder of diameter  $D$  with an insulated side surface for the case of constant thermal conductivity with heat generation.

FIGURE P2–34

### Boundary and Initial Conditions; Formulation of Heat Conduction Problems

**2–35C** What is a boundary condition? How many boundary conditions do we need to specify for a two-dimensional heat conduction problem?

**2–36C** What is an initial condition? How many initial conditions do we need to specify for a two-dimensional heat conduction problem?

**2–37C** What is a thermal symmetry boundary condition? How is it expressed mathematically?

**2–38C** How is the boundary condition on an insulated surface expressed mathematically?

**2–39C** It is claimed that the temperature profile in a medium must be perpendicular to an insulated surface. Is this a valid claim? Explain.

**2–40C** Why do we try to avoid the radiation boundary conditions in heat transfer analysis?

**2–41** Consider an aluminum pan used to cook stew on top of an electric range. The bottom section of the pan is  $L = 0.25$  cm thick and has a diameter of  $D = 18$  cm. The electric heating unit on the range top consumes 900 W of power during cooking, and 90 percent of the heat generated in the heating element is transferred to the pan. During steady operation, the temperature of the inner surface of the pan is measured to be 108°C. Assuming temperature-dependent thermal conductivity and one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary conditions) of this heat conduction problem during steady operation. Do not solve.

**2–42** Consider a steel pan used to boil water on top of an electric range. The bottom section of the pan is  $L = 0.3$  cm thick and has a diameter of  $D = 20$  cm. The electric heating unit on the range top consumes 1250 W of power during cooking, and 85 percent of the heat generated in the heating element is transferred uniformly to the pan. Heat transfer from the top surface of the bottom section to the water is by convection with a heat transfer coefficient of  $h$ . Assuming constant thermal conductivity and one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary conditions) of this heat conduction problem during steady operation. Do not solve.

FIGURE P2–42

**2–43** Consider the East wall of a house that has a thickness of  $L$ . The outer surface of the wall exchanges heat by both convection and radiation. The interior of the house is maintained at  $T_{\infty 1}$ , while the ambient air temperature outside remains at  $T_{\infty 2}$ . The sky, the ground, and the surfaces of the surrounding structures at this location can be modeled as a surface at an effective temperature of  $T_{\text{sky}}$  for radiation exchange on the outer surface. The radiation exchange between the inner surface of the wall and the surfaces of the walls, floor, and ceiling it faces is negligible. The convection heat transfer coefficients on the inner and outer surfaces of the wall are  $h_1$  and  $h_2$ , respectively. The thermal conductivity of the wall material is  $k$  and the emissivity of the outer surface is  $\varepsilon_2$ . Assuming the heat

transfer through the wall to be steady and one-dimensional, express the mathematical formulation (the differential equation and the boundary and initial conditions) of this heat conduction problem. Do not solve.

FIGURE P2-43

**2-44** Heat is generated in a long wire of radius  $r_o$  at a constant rate of  $\dot{e}_{gen}$  per unit volume. The wire is covered with a plastic insulation layer. Express the heat flux boundary condition at the interface in terms of the heat generated.

**2-45** Consider a long pipe of inner radius  $r_1$ , outer radius  $r_2$ , and thermal conductivity  $k$ . The outer surface of the pipe is subjected to convection to a medium at  $T_\infty$  with a heat transfer coefficient of  $h$ , but the direction of heat transfer is not known. Express the convection boundary condition on the outer surface of the pipe.

**2-46E** A 2-kW resistance heater wire whose thermal conductivity is  $k = 10.4 \text{ Btu/h}\cdot\text{ft}\cdot\text{R}$  has a radius of  $r_o = 0.06 \text{ in}$  and a length of  $L = 15 \text{ in}$ , and is used for space heating. Assuming constant thermal conductivity and one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary conditions) of this heat conduction problem during steady operation. Do not solve.

**2-47** Water flows through a pipe at an average temperature of  $T_\infty = 90^\circ\text{C}$ . The inner and outer radii of the pipe are  $r_1 = 6 \text{ cm}$  and  $r_2 = 6.5 \text{ cm}$ , respectively. The outer surface of the pipe is wrapped with a thin electric heater that consumes  $400 \text{ W}$  per m length of the pipe. The exposed surface of the heater is heavily insulated so that the entire heat generated in the heater is transferred to the pipe. Heat is transferred from the inner surface of the pipe to the water by convection with a heat transfer coefficient of  $h = 85 \text{ W/m}^2\cdot\text{K}$ . Assuming constant thermal conductivity and one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary conditions) of the heat conduction in the pipe during steady operation. Do not solve.

FIGURE P2-47

**2-48** Consider a spherical container of inner radius  $r_1$ , outer radius  $r_2$ , and thermal conductivity  $k$ . Express the boundary condition on the inner surface of the container for steady one-dimensional conduction for the following cases: (a) specified temperature of  $50^\circ\text{C}$ , (b) specified heat flux of  $45 \text{ W/m}^2$  toward the center, (c) convection to a medium at  $T_\infty$  with a heat transfer coefficient of  $h$ .

FIGURE P2-48

**2-49** Consider a spherical shell of inner radius  $r_1$ , outer radius  $r_2$ , thermal conductivity  $k$ , and emissivity  $\varepsilon$ . The outer surface of the shell is subjected to radiation to surrounding surfaces at  $T_{\text{surr}}$ , but the direction of heat transfer is not known. Express the radiation boundary condition on the outer surface of the shell.

**2-50** A container consists of two spherical layers, *A* and *B*, that are in perfect contact. If the radius of the interface is  $r_o$ , express the boundary conditions at the interface.

**2-51** A spherical metal ball of radius  $r_o$  is heated in an oven to a temperature of  $T_i$  throughout and is then taken out of the oven and dropped into a large body of water at  $T_\infty$  where it is cooled by convection with an average convection heat transfer coefficient of  $h$ . Assuming constant thermal conductivity and transient one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary and initial conditions) of this heat conduction problem. Do not solve.

**2-52** A spherical metal ball of radius  $r_o$  is heated in an oven to a temperature of  $T_i$  throughout and is then taken out of the

oven and allowed to cool in ambient air at  $T_\infty$  by convection and radiation. The emissivity of the outer surface of the cylinder is  $\varepsilon$ , and the temperature of the surrounding surfaces is  $T_{\text{surr}}$ . The average convection heat transfer coefficient is estimated to be  $h$ . Assuming variable thermal conductivity and transient one-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary and initial conditions) of this heat conduction problem. Do not solve.

FIGURE P2-52

### Solution of Steady One-Dimensional Heat Conduction Problems

**2-53C** It is stated that the temperature in a plane wall with constant thermal conductivity and no heat generation varies linearly during steady one-dimensional heat conduction. Will this still be the case when the wall loses heat by radiation from its surfaces?

**2-54C** Consider one-dimensional heat conduction through a large plane wall with no heat generation that is perfectly insulated on one side and is subjected to convection and radiation on the other side. It is claimed that under steady conditions, the temperature in a plane wall must be uniform (the same everywhere). Do you agree with this claim? Why?

**2-55C** Consider a solid cylindrical rod whose side surface is maintained at a constant temperature while the end surfaces are perfectly insulated. The thermal conductivity of the rod material is constant and there is no heat generation. It is claimed that the temperature in the radial direction within the rod will not vary during steady heat conduction. Do you agree with this claim? Why?

**2-56C** Consider a solid cylindrical rod whose ends are maintained at constant but different temperatures while the side surface is perfectly insulated. There is no heat generation. It is claimed that the temperature along the axis of the rod varies linearly during steady heat conduction. Do you agree with this claim? Why?

**2-57** Consider a large plane wall of thickness  $L = 0.3$  m, thermal conductivity  $k = 2.5$  W/m·K, and surface area  $A = 12$  m $^2$ . The left side of the wall at  $x = 0$  is subjected to a net heat flux of  $\dot{q}_0 = 700$  W/m $^2$  while the temperature at that surface is measured to be  $T_1 = 80^\circ\text{C}$ . Assuming constant thermal conductivity and no heat generation in the wall, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the wall, (b) obtain a relation for the variation of temperature in the wall by solving the differential equation, and (c) evaluate the temperature of the right surface of the wall at  $x = L$ . *Answer: (c)  $-4^\circ\text{C}$*

FIGURE P2-57

**2-58** Consider the base plate of an 800-W household iron with a thickness of  $L = 0.6$  cm, base area of  $A = 160$  cm $^2$ , and thermal conductivity of  $k = 60$  W/m·K. The inner surface of the base plate is subjected to uniform heat flux generated by the resistance heaters inside. When steady operating conditions are reached, the outer surface temperature of the plate is measured to be  $112^\circ\text{C}$ . Disregarding any heat loss through the upper part of the iron, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the plate, (b) obtain a relation for the variation of temperature in the base plate by solving the differential equation, and (c) evaluate the inner surface temperature. *Answer: (c)  $117^\circ\text{C}$*

FIGURE P2-58

**2-59** Consider a large plane wall of thickness  $L = 0.4$  m, thermal conductivity  $k = 1.8$  W/m·K, and surface area  $A = 30$  m $^2$ . The left side of the wall is maintained at a constant temperature of  $T_1 = 90^\circ\text{C}$  while the right side loses heat by convection to the surrounding air at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 24$  W/m $^2$ ·K. Assuming constant thermal conductivity and no heat generation in the wall, (a) express the

differential equation and the boundary conditions for steady one-dimensional heat conduction through the wall, (b) obtain a relation for the variation of temperature in the wall by solving the differential equation, and (c) evaluate the rate of heat transfer through the wall. *Answer: (c) 7389 W*

**2–60** Consider a 20-cm-thick large concrete plane wall ( $k = 0.77 \text{ W/m}\cdot\text{K}$ ) subjected to convection on both sides with  $T_{\infty 1} = 27^\circ\text{C}$  and  $h_1 = 5 \text{ W/m}^2\cdot\text{K}$  on the inside, and  $T_{\infty 2} = 8^\circ\text{C}$  and  $h_2 = 12 \text{ W/m}^2\cdot\text{K}$  on the outside. Assuming constant thermal conductivity with no heat generation and negligible radiation, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the wall, (b) obtain a relation for the variation of temperature in the wall by solving the differential equation, and (c) evaluate the temperatures at the inner and outer surfaces of the wall.

**2–61 Ptb** The outer surface of an engine is situated in a place where oil leakage can occur. Some oils have autoignition temperatures of approximately above  $250^\circ\text{C}$ . When oil comes in contact with a hot engine surface that has a higher temperature than its autoignition temperature, the oil can ignite spontaneously. Treating the engine housing as a plane wall, the inner surface ( $x = 0$ ) is subjected to  $6 \text{ kW/m}^2$  of heat. The engine housing ( $k = 13.5 \text{ W/m}\cdot\text{K}$ ) has a thickness of 1 cm, and the outer surface ( $x = L$ ) is exposed to an environment where the ambient air is  $35^\circ\text{C}$  with a convection heat transfer coefficient of  $20 \text{ W/m}^2\cdot\text{K}$ . To prevent fire hazard in the event the leaked oil comes in contact with the hot engine surface, the temperature of the engine surface should be kept below  $200^\circ\text{C}$ . Determine the variation of temperature in the engine housing and the temperatures of the inner and outer surfaces. Is the outer surface temperature of the engine below the safe temperature?

FIGURE P2–61

**2–62** A large plane wall has a thickness  $L = 50 \text{ cm}$  and thermal conductivity  $k = 25 \text{ W/m}\cdot\text{K}$ . On the left surface ( $x = 0$ ), it is subjected to a uniform heat flux  $\dot{q}_0$  while the surface temperature  $T_0$  is constant. On the right surface, it experiences convection and radiation heat transfer while the surface temperature is  $T_L = 225^\circ\text{C}$  and the surrounding temperature is  $25^\circ\text{C}$ .

The emissivity and the convection heat transfer coefficient on the right surface are 0.7 and  $15 \text{ W/m}^2\cdot\text{K}$ , respectively. Show that the variation of temperature in the wall can be expressed as  $T(x) = (\dot{q}_0/k)(L - x) + T_L$ , where  $\dot{q}_0 = 5130 \text{ W/m}^2$ , and determine the temperature of the left surface of the wall at  $x = 0$ .

FIGURE P2–62

**2–63** A flat-plate solar collector is used to heat water by having water flow through tubes attached at the back of the thin solar absorber plate. The absorber plate has an emissivity and an absorptivity of 0.9. The top surface ( $x = 0$ ) temperature of the absorber is  $T_0 = 35^\circ\text{C}$ , and solar radiation is incident on the absorber at  $500 \text{ W/m}^2$  with a surrounding temperature of  $0^\circ\text{C}$ . Convection heat transfer coefficient at the absorber surface is  $5 \text{ W/m}^2\cdot\text{K}$ , while the ambient temperature is  $25^\circ\text{C}$ . Show that the variation of temperature in the absorber plate can be expressed as  $T(x) = -(q̄₀/k)x + T_0$ , and determine net heat flux  $\dot{q}_0$  absorbed by the solar collector.

FIGURE P2–63

**2–64** Electrically heated draw batch furnaces are commonly used in the heat treatment industry. Consider a draw batch furnace front made of a 20-mm thick steel plate with a thermal conductivity of  $25 \text{ W/m}\cdot\text{K}$ . The furnace is situated in a room with surrounding air temperature of  $20^\circ\text{C}$  and an average convection heat transfer coefficient of  $10 \text{ W/m}^2\cdot\text{K}$ . If the inside surface of the furnace front is subjected to uniform heat flux of  $5 \text{ kW/m}^2$  and the outer surface has an emissivity of 0.30, determine the inside surface temperature of the furnace front.

FIGURE P2-64

**2-65E** A large steel plate having a thickness of  $L = 4$  in, thermal conductivity of  $k = 7.2 \text{ Btu/h} \cdot \text{ft} \cdot {}^\circ\text{F}$ , and an emissivity of  $\varepsilon = 0.7$  is lying on the ground. The exposed surface of the plate at  $x = L$  is known to exchange heat by convection with the ambient air at  $T_\infty = 90^\circ\text{F}$  with an average heat transfer coefficient of  $h = 12 \text{ Btu/h} \cdot \text{ft}^2 \cdot {}^\circ\text{F}$  as well as by radiation with the open sky with an equivalent sky temperature of  $T_{\text{sky}} = 480 \text{ R}$ . Also, the temperature of the upper surface of the plate is measured to be  $80^\circ\text{F}$ . Assuming steady one-dimensional heat transfer, (a) express the differential equation and the boundary conditions for heat conduction through the plate, (b) obtain a relation for the variation of temperature in the plate by solving the differential equation, and (c) determine the value of the lower surface temperature of the plate at  $x = 0$ .

FIGURE P2-65E

**2-66** Consider a solid cylindrical rod of length  $0.15 \text{ m}$  and diameter  $0.05 \text{ m}$ . The top and bottom surfaces of the rod are maintained at constant temperatures of  $20^\circ\text{C}$  and  $95^\circ\text{C}$ , respectively, while the side surface is perfectly insulated. Determine the rate of heat transfer through the rod if it is made of (a) copper,  $k = 380 \text{ W/m} \cdot \text{K}$ , (b) steel,  $k = 18 \text{ W/m} \cdot \text{K}$ , and (c) granite,  $k = 1.2 \text{ W/m} \cdot \text{K}$ .

**2-67** Consider a chilled-water pipe of length  $L$ , inner radius  $r_1$ , outer radius  $r_2$ , and thermal conductivity  $k$ . Water flows in the pipe at a temperature  $T_f$  and the heat transfer coefficient at the inner surface is  $h$ . If the pipe is well-insulated on the outer

surface, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the pipe and (b) obtain a relation for the variation of temperature in the pipe by solving the differential equation.

**2-68E** Consider a steam pipe of length  $L = 30 \text{ ft}$ , inner radius  $r_1 = 2 \text{ in}$ , outer radius  $r_2 = 2.4 \text{ in}$ , and thermal conductivity  $k = 7.2 \text{ Btu/h} \cdot \text{ft} \cdot {}^\circ\text{F}$ . Steam is flowing through the pipe at an average temperature of  $300^\circ\text{F}$ , and the average convection heat transfer coefficient on the inner surface is given to be  $h = 12.5 \text{ Btu/h} \cdot \text{ft}^2 \cdot {}^\circ\text{F}$ . If the average temperature on the outer surfaces of the pipe is  $T_2 = 175^\circ\text{F}$ , (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the pipe, (b) obtain a relation for the variation of temperature in the pipe by solving the differential equation, and (c) evaluate the rate of heat loss from the steam through the pipe. *Answer: (c) 46,630 Btu/h*

FIGURE P2-68E

**2-69** A pipe in a manufacturing plant is transporting superheated vapor at a mass flow rate of  $0.3 \text{ kg/s}$ . The pipe is  $10 \text{ m}$  long, has an inner diameter of  $5 \text{ cm}$  and pipe wall thickness of  $6 \text{ mm}$ . The pipe has a thermal conductivity of  $17 \text{ W/m} \cdot \text{K}$ , and the inner pipe surface is at a uniform temperature of  $120^\circ\text{C}$ . The temperature drop between the inlet and exit of the pipe is  $7^\circ\text{C}$ , and the constant pressure specific heat of vapor is  $2190 \text{ J/kg} \cdot {}^\circ\text{C}$ . If the air temperature in the manufacturing plant is  $25^\circ\text{C}$ , determine the heat transfer coefficient as a result of convection between the outer pipe surface and the surrounding air.

FIGURE P2-69

**2-70** In subsea oil and natural gas production, hydrocarbon fluids may leave the reservoir with a temperature of 70°C and flow in subsea surrounding of 5°C. As a result of the temperature difference between the reservoir and the subsea surrounding, the knowledge of heat transfer is critical to prevent gas hydrate and wax deposition blockages. Consider a subsea pipeline with inner diameter of 0.5 m and wall thickness of 8 mm is used for transporting liquid hydrocarbon at an average temperature of 70°C, and the average convection heat transfer coefficient on the inner pipeline surface is estimated to be 250 W/m<sup>2</sup>·K. The subsea surrounding has a temperature of 5°C and the average convection heat transfer coefficient on the outer pipeline surface is estimated to be 150 W/m<sup>2</sup>·K. If the pipeline is made of material with thermal conductivity of 60 W/m·K, by using the heat conduction equation (a) obtain the temperature variation in the pipeline wall, (b) determine the inner surface temperature of the pipeline, (c) obtain the mathematical expression for the rate of heat loss from the liquid hydrocarbon in the pipeline, and (d) determine the heat flux through the outer pipeline surface.

FIGURE P2-70

**2-71** Liquid ethanol is a flammable fluid that has a flashpoint at 16.6°C. At temperatures above the flashpoint, ethanol can release vapors that form explosive mixtures, which could ignite when source of ignition is present. In a chemical plant, liquid ethanol is being transported in a pipe ( $k = 15 \text{ W/m}\cdot\text{K}$ ) with an inside diameter of 3 cm and a wall thickness of 3 mm. The pipe passes through areas where occasional presence of ignition source can occur, and the pipe's outer surface is subjected to a heat flux of 1 kW/m<sup>2</sup>. The ethanol flowing in the pipe has an average temperature of 10°C with an average convection heat transfer coefficient of 50 W/m<sup>2</sup>·K. Your task as an engineer is to ensure that the ethanol is transported safely and prevent fire hazard. Determine the variation of temperature in the pipe wall and the temperatures of the inner and outer surfaces of the pipe. Are both surface temperatures safely below the flashpoint of liquid ethanol?

FIGURE P2-71

**2-72** A spherical container, with an inner radius  $r_1 = 1 \text{ m}$  and an outer radius  $r_2 = 1.05 \text{ m}$ , has its inner surface subjected to a uniform heat flux of  $\dot{q}_1 = 7 \text{ kW/m}^2$ . The outer surface of the container has a temperature  $T_2 = 25^\circ\text{C}$ , and the container wall thermal conductivity is  $k = 1.5 \text{ W/m}\cdot\text{K}$ . Show that the variation of temperature in the container wall can be expressed as  $T(r) = (\dot{q}_1 r_1^2/k)(1/r - 1/r_2) + T_2$  and determine the temperature of the inner surface of the container at  $r = r_1$ .

FIGURE P2-72

**2-73** A spherical shell, with thermal conductivity  $k$ , has inner and outer radii of  $r_1$  and  $r_2$ , respectively. The inner surface of the shell is subjected to a uniform heat flux of  $\dot{q}_1$ , while the outer surface of the shell is exposed to convection heat transfer with a coefficient  $h$  and an ambient temperature  $T_\infty$ . Determine the variation of temperature in the shell wall and show that the outer surface temperature of the shell can be expressed as  $T(r_2) = (\dot{q}_1/h)(r_1/r_2)^2 + T_\infty$ .

FIGURE P2-73

**2-74** A spherical container of inner radius  $r_1 = 2 \text{ m}$ , outer radius  $r_2 = 2.1 \text{ m}$ , and thermal conductivity  $k = 30 \text{ W/m}\cdot\text{K}$  is filled with iced water at 0°C. The container is gaining heat by convection from the surrounding air at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 18 \text{ W/m}^2\cdot\text{K}$ . Assuming the inner surface temperature of the container to be 0°C, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the container, (b) obtain a relation for the variation of temperature in the container by solving the differential equation, and (c) evaluate the rate of heat gain to the iced water.

**2-75** A stainless steel spherical container, with  $k = 15 \text{ W/m}\cdot\text{K}$  is used for storing chemicals undergoing exothermic reaction. The reaction provides a uniform heat

flux of  $60 \text{ kW/m}^2$  to the container's inner surface. The container has an inner radius of 50 cm and a wall thickness of 5 cm and is situated in a surrounding with an ambient temperature of  $23^\circ\text{C}$ . The container's outer surface is subjected to convection heat transfer with a coefficient of  $1000 \text{ W/m}^2\cdot\text{K}$ . For safety reasons to prevent thermal burn to individuals working around the container, it is necessary to keep the container's outer surface temperature below  $50^\circ\text{C}$ . Determine the variation of temperature in the container wall and the temperatures of the inner and outer surfaces of the container. Is the outer surface temperature of the container safe to prevent thermal burn?

**FIGURE P2–75**

**2–76** In a food processing facility, a spherical container of inner radius  $r_1 = 40 \text{ cm}$ , outer radius  $r_2 = 41 \text{ cm}$ , and thermal conductivity  $k = 1.5 \text{ W/m}\cdot\text{K}$  is used to store hot water and to keep it at  $100^\circ\text{C}$  at all times. To accomplish this, the outer surface of the container is wrapped with a 800-W electric strip heater and then insulated. The temperature of the inner surface of the container is observed to be nearly  $120^\circ\text{C}$  at all times. Assuming 10 percent of the heat generated in the heater is lost through the insulation, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the container, (b) obtain a relation for the variation of temperature in the container material by solving the differential equation, and (c) evaluate the outer surface temperature of the container. Also determine how much water at  $100^\circ\text{C}$  this tank can supply steadily if the cold water enters at  $20^\circ\text{C}$ .

**FIGURE P2–76**

**2–77** Reconsider Prob. 2–76. Using the relation obtained for the variation of temperature in the container material, plot the temperature as a function of the radius  $r$  in the range of  $r = r_1$  to  $r = r_2$ , and discuss the results. Use the EES (or other) software.

### Heat Generation in a Solid

**2–78C** What is heat generation? Give some examples.

**2–79C** Does heat generation in a solid violate the first law of thermodynamics, which states that energy cannot be created or destroyed? Explain.

**2–80C** Consider uniform heat generation in a cylinder and a sphere of equal radius made of the same material in the same environment. Which geometry will have a higher temperature at its center? Why?

**2–81C** An iron is left unattended and its base temperature rises as a result of resistance heating inside. When will the rate of heat generation inside the iron be equal to the rate of heat loss from the iron?

**2–82C** Consider the uniform heating of a plate in an environment at a constant temperature. Is it possible for part of the heat generated in the left half of the plate to leave the plate through the right surface? Explain.

**2–83** Consider a large 5-cm-thick brass plate ( $k = 111 \text{ W/m}\cdot\text{K}$ ) in which heat is generated uniformly at a rate of  $2 \times 10^5 \text{ W/m}^3$ . One side of the plate is insulated while the other side is exposed to an environment at  $25^\circ\text{C}$  with a heat transfer coefficient of  $44 \text{ W/m}^2\cdot\text{K}$ . Explain where in the plate the highest and the lowest temperatures will occur, and determine their values.

**FIGURE P2–83**

**2–84** Reconsider Prob. 2–83. Using EES (or other) software, investigate the effect of the heat transfer coefficient on the highest and lowest temperatures in the plate. Let the heat transfer coefficient vary from  $20 \text{ W/m}^2\cdot\text{K}$  to  $100 \text{ W/m}^2\cdot\text{K}$ . Plot the highest and lowest temperatures as a function of the heat transfer coefficient, and discuss the results.

**2–85** Consider a large 3-cm-thick stainless steel plate ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ) in which heat is generated uniformly at a rate of  $5 \times 10^5 \text{ W/m}^3$ . Both sides of the plate are exposed to an environment at  $30^\circ\text{C}$  with a heat transfer coefficient of  $60 \text{ W/m}^2\cdot\text{K}$ .

Explain where in the plate the highest and the lowest temperatures will occur, and determine their values.

- 2-86** Consider a large plate of thickness  $L$  and thermal conductivity  $k$  in which heat is generated uniformly at a rate of  $\dot{e}_{\text{gen}}$ . One side of the plate is insulated while the other side is exposed to an environment at  $T_{\infty}$  with a heat transfer coefficient of  $h$ . (a) Express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the plate, (b) determine the variation of temperature in the plate, and (c) obtain relations for the temperatures on both surfaces and the maximum temperature rise in the plate in terms of given parameters.

FIGURE P2-86

- 2-87E** Consider a large plane wall of thickness  $L$  and constant thermal conductivity  $k$ . The left side of the wall ( $x = 0$ ) is maintained at a constant temperature  $T_0$ , while the right surface at  $x = L$  is insulated. Heat is generated in the wall at the rate of  $\dot{e}_{\text{gen}} = ax^2 \text{ Btu/h}\cdot\text{ft}^3$ . Assuming steady one-dimensional heat transfer, (a) express the differential equation and the boundary conditions for heat conduction through the wall, (b) by solving the differential equation, obtain a relation for the variation of temperature in the wall  $T(x)$  in terms of  $x$ ,  $L$ ,  $k$ ,  $a$ , and  $T_0$ , and (c) what is the highest temperature ( $^{\circ}\text{C}$ ) in the plane wall when:  $L = 1 \text{ ft}$ ,  $k = 5 \text{ Btu/h}\cdot\text{ft}\cdot^{\circ}\text{F}$ ,  $a = 1200 \text{ Btu/h}\cdot\text{ft}^5$ , and  $T_0 = 700^{\circ}\text{F}$ .

FIGURE P2-87E

- 2-88** Consider a large plane wall of thickness  $L = 0.05 \text{ m}$ . The wall surface at  $x = 0$  is insulated, while the surface at  $x = L$  is maintained at a temperature of  $30^{\circ}\text{C}$ . The thermal conductivity of the wall is  $k = 30 \text{ W/m}\cdot\text{K}$ , and heat is generated in the wall at a rate of  $\dot{e}_{\text{gen}} = \dot{e}_0 e^{-0.5x/L} \text{ W/m}^3$  where  $\dot{e}_0 = 8 \times 10^6 \text{ W/m}^3$ . Assuming steady one-dimensional heat transfer, (a) express the differential equation and the boundary

conditions for heat conduction through the wall, (b) obtain a relation for the variation of temperature in the wall by solving the differential equation, and (c) determine the temperature of the insulated surface of the wall. *Answer: (c)  $314^{\circ}\text{C}$*

- 2-89** Reconsider Prob. 2-88. Using the relation given for the heat generation in the wall, plot the heat generation as a function of the distance  $x$  in the range of  $x = 0$  to  $x = L$ , and discuss the results. Use the EES (or other) software.

- 2-90** In a nuclear reactor, 1-cm-diameter cylindrical uranium rods cooled by water from outside serve as the fuel. Heat is generated uniformly in the rods ( $k = 29.5 \text{ W/m}\cdot\text{K}$ ) at a rate of  $4 \times 10^7 \text{ W/m}^3$ . If the outer surface temperature of rods is  $220^{\circ}\text{C}$ , determine the temperature at their center.

FIGURE P2-90

- 2-91E** Heat is generated uniformly at a rate of  $3 \text{ kW per ft length}$  in a  $0.08\text{-in-diameter}$  electric resistance wire made of nickel steel ( $k = 5.8 \text{ Btu/h}\cdot\text{ft}\cdot^{\circ}\text{F}$ ). Determine the temperature difference between the centerline and the surface of the wire.

- 2-92** A  $2\text{-kW}$  resistance heater wire with thermal conductivity of  $k = 20 \text{ W/m}\cdot\text{K}$ , a diameter of  $D = 4 \text{ mm}$ , and a length of  $L = 0.9 \text{ m}$  is used to boil water. If the outer surface temperature of the resistance wire is  $T_s = 230^{\circ}\text{C}$ , determine the temperature at the center of the wire.

FIGURE P2-92

- 2-93** Consider a long solid cylinder of radius  $r_o = 4 \text{ cm}$  and thermal conductivity  $k = 25 \text{ W/m}\cdot\text{K}$ . Heat is generated in the cylinder uniformly at a rate of  $\dot{e}_{\text{gen}} = 35 \text{ W/cm}^3$ . The side surface of the cylinder is maintained at a constant temperature of  $T_s = 80^{\circ}\text{C}$ . The variation of temperature in the cylinder is given by

$$T(r) = \frac{\dot{e}_{\text{gen}} r_o^2}{k} \left[ 1 - \left[ 1 - \left( \frac{r}{r_o} \right)^2 \right] \right] + T_s$$

Based on this relation, determine (a) if the heat conduction is steady or transient, (b) if it is one-, two-, or three-dimensional, and (c) the value of heat flux on the side surface of the cylinder at  $r = r_o$ .

**2–94**  Reconsider Prob. 2–93. Using the relation obtained for the variation of temperature in the cylinder, plot the temperature as a function of the radius  $r$  in the range of  $r = 0$  to  $r = r_o$ , and discuss the results. Use the EES (or other) software.

**2–95** A cylindrical nuclear fuel rod of 1 cm in diameter is encased in a concentric tube of 2 cm in diameter, where cooling water flows through the annular region between the fuel rod ( $k = 30 \text{ W/m}\cdot\text{K}$ ) and the concentric tube. Heat is generated uniformly in the rod at a rate of  $50 \text{ MW/m}^3$ . The convection heat transfer coefficient for the concentric tube surface is  $2000 \text{ W/m}^2\cdot\text{K}$ . If the surface temperature of the concentric tube is  $40^\circ\text{C}$ , determine the average temperature of the cooling water. Can one use the given information to determine the surface temperature of the fuel rod? Explain. *Answer:  $71.3^\circ\text{C}$*

FIGURE P2–95

**2–96** Consider a solid stainless steel wire with a thermal conductivity of  $14 \text{ W/m}\cdot\text{K}$ . The wire has a diameter of 1 mm, a resistivity of  $45 \times 10^{-8} \Omega\cdot\text{m}$ , and carries a current of 120 A. (a) Determine the rate of heat generated within the wire ( $\text{W/m}^3$ ) and (b) calculate the maximum temperature rise in the wire.

FIGURE P2–96

**2–97** A long homogeneous resistance wire of radius  $r_o = 0.6 \text{ cm}$  and thermal conductivity  $k = 15.2 \text{ W/m}\cdot\text{K}$  is being used to boil water at atmospheric pressure by the passage of electric current. Heat is generated in the wire uniformly as a result of resistance heating at a rate of  $16.4 \text{ W/cm}^3$ . The heat generated is transferred to water at  $100^\circ\text{C}$  by convection with

an average heat transfer coefficient of  $h = 3200 \text{ W/m}^2\cdot\text{K}$ . Assuming steady one-dimensional heat transfer, (a) express the differential equation and the boundary conditions for heat conduction through the wire, (b) obtain a relation for the variation of temperature in the wire by solving the differential equation, and (c) determine the temperature at the centerline of the wire. *Answer: (c)  $125^\circ\text{C}$*

FIGURE P2–97

**2–98** A 6-m-long 3-kW electrical resistance wire is made of 0.2-cm-diameter stainless steel ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ). The resistance wire operates in an environment at  $20^\circ\text{C}$  with a heat transfer coefficient of  $175 \text{ W/m}^2\cdot\text{K}$  at the outer surface. Determine the surface temperature of the wire (a) by using the applicable relation and (b) by setting up the proper differential equation and solving it. *Answers: (a)  $475^\circ\text{C}$ , (b)  $475^\circ\text{C}$*

**2–99** A long homogeneous resistance wire of radius  $r_o = 5 \text{ mm}$  is being used to heat the air in a room by the passage of electric current. Heat is generated in the wire uniformly at a rate of  $5 \times 10^7 \text{ W/m}^3$  as a result of resistance heating. If the temperature of the outer surface of the wire remains at  $180^\circ\text{C}$ , determine the temperature at  $r = 3.5 \text{ mm}$  after steady operation conditions are reached. Take the thermal conductivity of the wire to be  $k = 6 \text{ W/m}\cdot\text{K}$ . *Answer:  $207^\circ\text{C}$*

FIGURE P2–99

**2–100**  A cylindrical fuel rod ( $k = 30 \text{ W/m}\cdot\text{K}$ ) of 2 cm in diameter is encased in a concentric tube and cooled by water. The fuel rod generates heat uniformly at a rate of  $100 \text{ MW/m}^3$ , and the average temperature of the cooling water is  $75^\circ\text{C}$  with a convection heat transfer coefficient of  $2500 \text{ W/m}^2\cdot\text{K}$ . The operating pressure of the cooling water is such that the surface temperature of the fuel rod must be kept below  $200^\circ\text{C}$  to avoid the cooling water from reaching the critical heat flux (CHF). The critical heat flux is a thermal limit at which a boiling crisis can occur that cause overheating on the fuel rod surface and lead to damage. Determine the variation of

temperature in the fuel rod and the temperature of the fuel rod surface. Is the surface of the fuel rod adequately cooled?

**FIGURE P2–100**

**2–101** Consider a homogeneous spherical piece of radioactive material of radius  $r_o = 0.04 \text{ m}$  that is generating heat at a constant rate of  $\dot{e}_{\text{gen}} = 5 \times 10^7 \text{ W/m}^3$ . The heat generated is dissipated to the environment steadily. The outer surface of the sphere is maintained at a uniform temperature of  $110^\circ\text{C}$  and the thermal conductivity of the sphere is  $k = 15 \text{ W/m}\cdot\text{K}$ . Assuming steady one-dimensional heat transfer, (a) express the differential equation and the boundary conditions for heat conduction through the sphere, (b) obtain a relation for the variation of temperature in the sphere by solving the differential equation, and (c) determine the temperature at the center of the sphere.

**FIGURE P2–101**

**2–102** Reconsider Prob. 2–101. Using the relation obtained for the variation of temperature in the sphere, plot the temperature as a function of the radius  $r$  in the range of  $r = 0$  to  $r = r_o$ . Also, plot the center temperature of the sphere as a function of the thermal conductivity in the range of  $10 \text{ W/m}\cdot\text{K}$  to  $400 \text{ W/m}\cdot\text{K}$ . Discuss the results. Use the EES (or other) software.

**2–103** A spherical communication satellite with a diameter of  $2.5 \text{ m}$  is orbiting around the earth. The outer surface of the satellite in space has an emissivity of  $0.75$  and a solar absorptivity of  $0.10$ , while solar radiation is incident on the spacecraft at a rate of  $1000 \text{ W/m}^2$ . If the satellite is made of material with an average thermal conductivity of  $5 \text{ W/m}\cdot\text{K}$  and the midpoint temperature is  $0^\circ\text{C}$ , determine the heat generation rate and the surface temperature of the satellite.

**FIGURE P2–103**

### Variable Thermal Conductivity

**2–104C** Is the thermal conductivity of a medium, in general, constant or does it vary with temperature?

**2–105C** When the thermal conductivity of a medium varies linearly with temperature, is the average thermal conductivity always equivalent to the conductivity value at the average temperature?

**2–106C** The temperature of a plane wall during steady one-dimensional heat conduction varies linearly when the thermal conductivity is constant. Is this still the case when the thermal conductivity varies linearly with temperature?

**2–107C** Consider steady one-dimensional heat conduction in a plane wall in which the thermal conductivity varies linearly. The error involved in heat transfer calculations by assuming constant thermal conductivity at the average temperature is (a) none, (b) small, or (c) significant.

**2–108C** Consider steady one-dimensional heat conduction in a plane wall, long cylinder, and sphere with constant thermal conductivity and no heat generation. Will the temperature in any of these mediums vary linearly? Explain.

**2–109** A silicon wafer with thickness of  $925 \mu\text{m}$  is being heated with a uniform heat flux at the lower surface. The silicon wafer has a thermal conductivity that varies with temperature and can be expressed as  $k(T) = (a + bT + cT^2) \text{ W/m}\cdot\text{K}$ , where  $a = 437$ ,  $b = -1.29$ , and  $c = 0.00111$ . To avoid warping, the temperature difference across the wafer thickness cannot exceed  $2^\circ\text{C}$ . If the upper surface of the silicon wafer is at a uniform temperature of  $600 \text{ K}$ , determine the maximum allowable heat flux.

**FIGURE P2–109**

**2–110** Consider a 1.5-m-high and 0.6-m-wide plate whose thickness is 0.15 m. One side of the plate is maintained at a constant temperature of 500 K while the other side is maintained at 350 K. The thermal conductivity of the plate can be assumed to vary linearly in that temperature range as  $k(T) = k_0(1 + \beta T)$  where  $k_0 = 18 \text{ W/m}\cdot\text{K}$  and  $\beta = 8.7 \times 10^{-4} \text{ K}^{-1}$ . Disregarding the edge effects and assuming steady one-dimensional heat transfer, determine the rate of heat conduction through the plate. *Answer: 22.2 kW*

**2–111** On the left side, a steel plate is subjected to a uniform heat flux of  $50 \text{ kW/m}^2$  and maintained at a constant temperature of 800 K. On the right side, the temperature is maintained at 600 K. The steel plate has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 9.14 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0023 \text{ K}^{-1}$ , and  $T$  is in K. Determine the thickness of the steel plate (in m).

**2–112** Consider a plane wall of thickness  $L$  whose thermal conductivity varies in a specified temperature range as  $k(T) = k_0(1 + \beta T^2)$  where  $k_0$  and  $\beta$  are two specified constants. The wall surface at  $x = 0$  is maintained at a constant temperature of  $T_1$ , while the surface at  $x = L$  is maintained at  $T_2$ . Assuming steady one-dimensional heat transfer, obtain a relation for the heat transfer rate through the wall.

**2–113** The thermal conductivity of stainless steel has been characterized experimentally to vary with temperature as  $k(T) = 9.14 + 0.021T$  for  $273 < T < 1500 \text{ K}$ , where  $k$  is in  $\text{W/m}\cdot\text{K}$  and  $T$  is in K. Determine the average thermal conductivity between 300 and 1200 K, and express  $k(T)$  in the form of  $k(T) = k_0(1 + \beta T)$ , where  $k_0$  is in  $\text{W/m}\cdot\text{K}$  and  $\beta$  is in  $\text{K}^{-1}$ .

**2–114** A circular metal pipe has a wall thickness of 10 mm and an inner diameter of 10 cm. The pipe's outer surface is subjected to a uniform heat flux of  $5 \text{ kW/m}^2$  and has a temperature of  $500^\circ\text{C}$ . The metal pipe has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 7.5 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0012 \text{ K}^{-1}$ , and  $T$  is in K. Determine the inner surface temperature of the pipe.

FIGURE P2–114

**2–115** A pipe is used for transporting boiling water in which the inner surface is at  $100^\circ\text{C}$ . The pipe is situated in surroundings where the ambient temperature

is  $10^\circ\text{C}$  and the convection heat transfer coefficient is  $70 \text{ W/m}^2\cdot\text{K}$ . The wall thickness of the pipe is 3 mm and its inner diameter is 30 mm. The pipe wall has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 1.23 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.002 \text{ K}^{-1}$ , and  $T$  is in K. For safety reasons and to prevent thermal burn to workers, the outer surface temperature of the pipe should be kept below  $50^\circ\text{C}$ . Determine whether the outer surface temperature of the pipe is at a safe temperature so as to avoid thermal burn.

**2–116** A pipe is used for transporting hot fluid in which the inner surface is at  $150^\circ\text{C}$ . The pipe has a wall thickness of 5 mm and an inner diameter of 15 cm. The pipe wall has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 8.5 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.001 \text{ K}^{-1}$ , and  $T$  is in K. The pipe is situated in surroundings of freezing air at  $0^\circ\text{C}$  with a convection heat transfer coefficient of  $60 \text{ W/m}^2\cdot\text{K}$  on the pipe's outer surface. Solar radiation is incident on the pipe's outer surface at a rate of  $100 \text{ W/m}^2$ , and both the emissivity and solar absorptivity of the outer surface are 0.9. Determine the outer surface temperature of the pipe.

FIGURE P2–116

**2–117** A spherical container, with an inner radius of 1 m and a wall thickness of 5 mm, has its inner surface subjected to a uniform heat flux of  $7 \text{ kW/m}^2$ . The outer surface of the container is maintained at  $20^\circ\text{C}$ . The container wall is made of a material with a thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 1.33 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0023 \text{ K}^{-1}$ , and  $T$  is in K. Determine the temperature drop across the container wall thickness.

FIGURE P2–117

**2-118** Consider a spherical shell of inner radius  $r_1$  and outer radius  $r_2$  whose thermal conductivity varies linearly in a specified temperature range as  $k(T) = k_0(1 + \beta T)$  where  $k_0$  and  $\beta$  are two specified constants. The inner surface of the shell is maintained at a constant temperature of  $T_1$  while the outer surface is maintained at  $T_2$ . Assuming steady one-dimensional heat transfer, obtain a relation for (a) the heat transfer rate through the shell and (b) the temperature distribution  $T(r)$  in the shell.

**2-119**  A spherical vessel is filled with chemicals undergoing an exothermic reaction. The reaction provides a uniform heat flux on the inner surface of the vessel. The inner diameter of the vessel is 5 m and its inner surface temperature is at 120°C. The wall of the vessel has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 1.01 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0018 \text{ K}^{-1}$ , and  $T$  is in K. The vessel is situated in a surrounding with an ambient temperature of 15°C, the vessel's outer surface experiences convection heat transfer with a coefficient of 80 W/m<sup>2</sup>·K. To prevent thermal burn on skin tissues, the outer surface temperature of the vessel should be kept below 50°C. Determine the minimum wall thickness of the vessel so that the outer surface temperature is 50°C or lower.

**2-120**  A spherical tank is filled with ice slurry, where its inner surface is at 0°C. The tank has an inner diameter of 9 m and its wall thickness is 20 mm. The tank wall is made of a material with a thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 0.33 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0025 \text{ K}^{-1}$ , and  $T$  is in K. The tank is in a surrounding temperature of 35°C and a convection heat transfer coefficient of 70 W/m<sup>2</sup>·K. Solar radiation is incident on the tank's outer surface at a rate of 150 W/m<sup>2</sup>, where the emissivity and solar absorptivity of the outer surface are 0.75. Determine the outer surface temperature of the tank.

### Special Topic: Review of Differential Equations

**2-121C** Why do we often utilize simplifying assumptions when we derive differential equations?

**2-122C** What is a variable? How do you distinguish a dependent variable from an independent one in a problem?

**2-123C** Can a differential equation involve more than one independent variable? Can it involve more than one dependent variable? Give examples.

**2-124C** What is the geometrical interpretation of a derivative? What is the difference between partial derivatives and ordinary derivatives?

**2-125C** What is the difference between the degree and the order of a derivative?

**2-126C** Consider a function  $f(x, y)$  and its partial derivative  $\partial f / \partial x$ . Under what conditions will this partial derivative be equal to the ordinary derivative  $df/dx$ ?

**2-127C** Consider a function  $f(x)$  and its derivative  $df/dx$ . Does this derivative have to be a function of  $x$ ?

**2-128C** How is integration related to derivation?

**2-129C** What is the difference between an algebraic equation and a differential equation?

**2-130C** What is the difference between an ordinary differential equation and a partial differential equation?

**2-131C** How is the order of a differential equation determined?

**2-132C** How do you distinguish a linear differential equation from a nonlinear one?

**2-133C** How do you recognize a linear homogeneous differential equation? Give an example and explain why it is linear and homogeneous.

**2-134C** How do differential equations with constant coefficients differ from those with variable coefficients? Give an example for each type.

**2-135C** What kind of differential equations can be solved by direct integration?

**2-136C** Consider a third order linear and homogeneous differential equation. How many arbitrary constants will its general solution involve?

### Review Problems

**2-137** A large plane wall, with a thickness  $L$  and a thermal conductivity  $k$ , has its left surface ( $x = 0$ ) exposed to a uniform heat flux  $\dot{q}_0$ . On the right surface ( $x = L$ ), convection and radiation heat transfer occur in a surrounding temperature of  $T_\infty$ . The emissivity and the convection heat transfer coefficient on the right surface are  $\varepsilon$  and  $h$ , respectively. Express the boundary conditions and the differential equation of this heat conduction problem during steady operation.

**2-138** Consider a long rectangular bar of length  $a$  in the  $x$ -direction and width  $b$  in the  $y$ -direction that is initially at a uniform temperature of  $T_i$ . The surfaces of the bar at  $x = 0$  and  $y = 0$  are insulated, while heat is lost from the other two surfaces by convection to the surrounding medium at temperature  $T_\infty$  with a heat transfer coefficient of  $h$ . Assuming constant thermal conductivity and transient two-dimensional heat transfer with no heat generation, express the mathematical formulation (the differential equation and the boundary and initial conditions) of this heat conduction problem. Do not solve.

FIGURE P2-138

**2–139E** Consider a large plane wall of thickness  $L = 0.8$  ft and thermal conductivity  $k = 1.2 \text{ Btu/h}\cdot\text{ft}^{\circ}\text{F}$ . The wall is covered with a material that has an emissivity of  $\varepsilon = 0.80$  and a solar absorptivity of  $\alpha = 0.60$ . The inner surface of the wall is maintained at  $T_1 = 520 \text{ R}$  at all times, while the outer surface is exposed to solar radiation that is incident at a rate of  $\dot{q}_{\text{solar}} = 300 \text{ Btu/h}\cdot\text{ft}^2$ . The outer surface is also losing heat by radiation to deep space at 0 K. Determine the temperature of the outer surface of the wall and the rate of heat transfer through the wall when steady operating conditions are reached. *Answers: 554 R, 50.9 Btu/h·ft<sup>2</sup>*

FIGURE P2–139E

**2–140** A spherical vessel has an inner radius  $r_1$  and an outer radius  $r_2$ . The inner surface ( $r = r_1$ ) of the vessel is subjected to a uniform heat flux  $\dot{q}_1$ . The outer surface ( $r = r_2$ ) is exposed to convection and radiation heat transfer in a surrounding temperature of  $T_{\infty}$ . The emissivity and the convection heat transfer coefficient on the outer surface are  $\varepsilon$  and  $h$ , respectively. Express the boundary conditions and the differential equation of this heat conduction problem during steady operation.

**2–141** Consider a short cylinder of radius  $r_o$  and height  $H$  in which heat is generated at a constant rate of  $\dot{e}_{\text{gen}}$ . Heat is lost from the cylindrical surface at  $r = r_o$  by convection to the surrounding medium at temperature  $T_{\infty}$  with a heat transfer coefficient of  $h$ . The bottom surface of the cylinder at  $z = 0$  is insulated, while the top surface at  $z = H$  is subjected to uniform heat flux  $\dot{q}_H$ . Assuming constant thermal conductivity and steady two-dimensional heat transfer, express the mathematical formulation (the differential equation and the boundary conditions) of this heat conduction problem. Do not solve.

**2–142** Consider a small hot metal object of mass  $m$  and specific heat  $c$  that is initially at a temperature of  $T_i$ . Now the object is allowed to cool in an environment at  $T_{\infty}$  by convection with a heat transfer coefficient of  $h$ . The temperature of the metal object is observed to vary uniformly with time during cooling. Writing an energy balance on the entire metal

object, derive the differential equation that describes the variation of temperature of the ball with time,  $T(t)$ . Assume constant thermal conductivity and no heat generation in the object. Do not solve.

FIGURE P2–142

**2–143** A 1200-W iron is left on the iron board with its base exposed to ambient air at  $26^\circ\text{C}$ . The base plate of the iron has a thickness of  $L = 0.5 \text{ cm}$ , base area of  $A = 150 \text{ cm}^2$ , and thermal conductivity of  $k = 18 \text{ W/m}\cdot\text{K}$ . The inner surface of the base plate is subjected to uniform heat flux generated by the resistance heaters inside. The outer surface of the base plate whose emissivity is  $\varepsilon = 0.7$ , loses heat by convection to ambient air with an average heat transfer coefficient of  $h = 30 \text{ W/m}^2\cdot\text{K}$  as well as by radiation to the surrounding surfaces at an average temperature of  $T_{\text{surr}} = 295 \text{ K}$ . Disregarding any heat loss through the upper part of the iron, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the plate, (b) obtain a relation for the temperature of the outer surface of the plate by solving the differential equation, and (c) evaluate the outer surface temperature.

FIGURE P2–143

**2–144** Consider a 20-cm-thick large concrete plane wall ( $k = 0.77 \text{ W/m}\cdot\text{K}$ ) subjected to convection on both sides with  $T_{\infty 1} = 22^\circ\text{C}$  and  $h_1 = 8 \text{ W/m}^2\cdot\text{K}$  on the inside, and  $T_{\infty 2} = 8^\circ\text{C}$  and  $h_2 = 12 \text{ W/m}^2\cdot\text{K}$  on the outside. Assuming constant thermal conductivity with no heat generation and negligible radiation, (a) express the differential equations and the

boundary conditions for steady one-dimensional heat conduction through the wall, (b) obtain a relation for the variation of temperature in the wall by solving the differential equation, and (c) evaluate the temperatures at the inner and outer surfaces of the wall.

**2-145** Consider a steam pipe of length  $L$ , inner radius  $r_1$ , outer radius  $r_2$ , and constant thermal conductivity  $k$ . Steam flows inside the pipe at an average temperature of  $T_i$  with a convection heat transfer coefficient of  $h_i$ . The outer surface of the pipe is exposed to convection to the surrounding air at a temperature of  $T_0$  with a heat transfer coefficient of  $h_o$ . Assuming steady one-dimensional heat conduction through the pipe, (a) express the differential equation and the boundary conditions for heat conduction through the pipe material, (b) obtain a relation for the variation of temperature in the pipe material by solving the differential equation, and (c) obtain a relation for the temperature of the outer surface of the pipe.

FIGURE P2-145

**2-146** Exhaust gases from a manufacturing plant are being discharged through a 10-m tall exhaust stack with outer diameter of 1 m, wall thickness of 10 cm, and thermal conductivity of 40 W/m·K. The exhaust gases are discharged at a rate of 1.2 kg/s, while temperature drop between inlet and exit of the exhaust stack is 30°C, and the constant pressure specific heat of the exhaust gasses is 1600 J/kg·K. On a particular day, the outer surface of the exhaust stack experiences radiation with the surrounding at 27°C, and convection with the ambient air at 27°C also, with an average convection heat transfer coefficient of 8 W/m<sup>2</sup>·K. Solar radiation is incident on the exhaust stack outer surface at a rate of 150 W/m<sup>2</sup>, and both the emissivity and solar absorptivity of the outer surface are 0.9. Assuming steady one-dimensional heat transfer, (a) obtain the variation of temperature in the exhaust stack wall and (b) determine the inner surface temperature of the exhaust stack.

FIGURE P2-146

**2-147E** Consider a steam pipe of length  $L = 35$  ft, inner radius  $r_1 = 2$  in, outer radius  $r_2 = 2.4$  in, and thermal conductivity  $k = 8 \text{ Btu/h}\cdot\text{ft}^\circ\text{F}$ . Steam is flowing through the pipe at an average temperature of 250°F, and the average convection heat transfer coefficient on the inner surface is given to be  $h = 15 \text{ Btu/h}\cdot\text{ft}^2\cdot\text{°F}$ . If the average temperature on the outer surfaces of the pipe is  $T_2 = 160^\circ\text{F}$ , (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the pipe, (b) obtain a relation for the variation of temperature in the pipe by solving the differential equation, and (c) evaluate the rate of heat loss from the steam through the pipe.

FIGURE P2-147E

**2-148** When a long section of a compressed air line passes through the outdoors, it is observed that the moisture in the compressed air freezes in cold weather, disrupting and even completely blocking the air flow in the pipe. To avoid this problem, the outer surface of the pipe is wrapped with electric strip heaters and then insulated. Consider a compressed air pipe of length  $L = 6$  m, inner radius  $r_1 = 3.7$  cm, outer radius  $r_2 = 4.0$  cm, and thermal conductivity  $k = 14$  W/m·K equipped with a 300-W strip heater. Air is flowing through the pipe at an average temperature of  $-10^\circ\text{C}$ , and the average convection heat transfer coefficient on the inner surface is  $h = 30 \text{ W/m}^2\cdot\text{K}$ . Assuming 15 percent of the heat generated

in the strip heater is lost through the insulation, (a) express the differential equation and the boundary conditions for steady one-dimensional heat conduction through the pipe, (b) obtain a relation for the variation of temperature in the pipe material by solving the differential equation, and (c) evaluate the inner and outer surface temperatures of the pipe.

**FIGURE P2-148**

**2-149** In a manufacturing plant, a quench hardening process is used to treat steel ball bearings ( $c = 500 \text{ J/kg}\cdot\text{K}$ ,  $k = 60 \text{ W/m}\cdot\text{K}$ ,  $\rho = 7900 \text{ kg/m}^3$ ) of 25 mm in diameter. After being heated to a prescribed temperature, the steel ball bearings are quenched. Determine the rate of heat loss if the rate of temperature decrease in the ball bearing at a given instant during the quenching process is 50 K/s. *Answer: 1.62 kW*

**2-150** Consider a water pipe of length  $L = 17 \text{ m}$ , inner radius  $r_1 = 15 \text{ cm}$ , outer radius  $r_2 = 20 \text{ cm}$ , and thermal conductivity  $k = 14 \text{ W/m}\cdot\text{K}$ . Heat is generated in the pipe material uniformly by a 25-kW electric resistance heater. The inner and outer surfaces of the pipe are at  $T_1 = 60^\circ\text{C}$  and  $T_2 = 80^\circ\text{C}$ , respectively. Obtain a general relation for temperature distribution inside the pipe under steady conditions and determine the temperature at the center plane of the pipe.

**2-151** Heat is generated uniformly at a rate of  $4.2 \times 10^6 \text{ W/m}^3$  in a spherical ball ( $k = 45 \text{ W/m}\cdot\text{K}$ ) of diameter 24 cm. The ball is exposed to iced-water at  $0^\circ\text{C}$  with a heat transfer coefficient of  $1200 \text{ W/m}^2\cdot\text{K}$ . Determine the temperatures at the center and the surface of the ball.

**2-152** Consider a spherical reactor of 5-cm diameter operating at steady condition has a temperature variation that can be expressed in the form of  $T(r) = a - br^2$ , where  $a = 850^\circ\text{C}$  and  $b = 5 \times 10^5 \text{ K/m}^2$ . The reactor is made of material with  $c = 200 \text{ J/kg}\cdot\text{°C}$ ,  $k = 40 \text{ W/m}\cdot\text{K}$ ,  $\rho = 9000 \text{ kg/m}^3$ . If the heat generation of reactor is suddenly set to  $9 \text{ MW/m}^3$ , determine the time rate of temperature change in the reactor. Is the heat generation of reactor suddenly increased or decreased to  $9 \text{ MW/m}^3$  from its steady operating condition?

**2-153** Consider a cylindrical shell of length  $L$ , inner radius  $r_1$ , and outer radius  $r_2$  whose thermal conductivity varies in a specified temperature range as  $k(T) = k_0(1 + \beta T^2)$  where  $k_0$  and  $\beta$  are two specified constants. The inner surface of the

shell is maintained at a constant temperature of  $T_1$  while the outer surface is maintained at  $T_2$ . Assuming steady one-dimensional heat transfer, obtain a relation for the heat transfer rate through the shell.

**2-154** A pipe is used for transporting boiling water in which the inner surface is at  $100^\circ\text{C}$ . The pipe is situated in a surrounding where the ambient temperature is  $20^\circ\text{C}$  and the convection heat transfer coefficient is  $50 \text{ W/m}^2\cdot\text{K}$ . The pipe has a wall thickness of 3 mm and an inner diameter of 25 mm, and it has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 1.5 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.003 \text{ K}^{-1}$ , and  $T$  is in K. Determine the outer surface temperature of the pipe.

**2-155** A metal spherical tank is filled with chemicals undergoing an exothermic reaction. The reaction provides a uniform heat flux on the inner surface of the tank. The tank has an inner diameter of 5 m and its wall thickness is 10 mm. The tank wall has a variable thermal conductivity given as  $k(T) = k_0(1 + \beta T)$ , where  $k_0 = 9.1 \text{ W/m}\cdot\text{K}$ ,  $\beta = 0.0018 \text{ K}^{-1}$ , and  $T$  is in K. The tank is situated in a surrounding with an ambient temperature of  $15^\circ\text{C}$ , the tank's outer surface experiences convection heat transfer with a coefficient of  $80 \text{ W/m}^2\cdot\text{K}$ . Determine the heat flux on the tank's inner surface if the inner surface temperature is  $120^\circ\text{C}$ .

### Fundamentals of Engineering (FE) Exam Problems

**2-156** The heat conduction equation in a medium is given in its simplest form as

$$\frac{1}{r} \frac{d}{dr} \left( rk \frac{dT}{dr} \right) + \dot{e}_{\text{gen}} = 0$$

Select the wrong statement below.

- (a) The medium is of cylindrical shape.
- (b) The thermal conductivity of the medium is constant.
- (c) Heat transfer through the medium is steady.
- (d) There is heat generation within the medium.
- (e) Heat conduction through the medium is one-dimensional.

**2-157** Consider a medium in which the heat conduction equation is given in its simplest forms as

$$\frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial T}{\partial r} \right) = \frac{1}{\alpha} \frac{\partial T}{\partial t}$$

- (a) Is heat transfer steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the thermal conductivity of the medium constant or variable?
- (e) Is the medium a plane wall, a cylinder, or a sphere?
- (f) Is this differential equation for heat conduction linear or nonlinear?

**2-158** Consider a large plane wall of thickness  $L$ , thermal conductivity  $k$ , and surface area  $A$ . The left surface of the wall is exposed to the ambient air at  $T_\infty$  with a heat transfer coefficient of  $h$  while the right surface is insulated. The variation of temperature in the wall for steady one-dimensional heat conduction with no heat generation is

- (a)  $T(x) = \frac{h(L-x)}{k} T_\infty$
- (b)  $T(x) = \frac{k}{h(x+0.5L)} T_\infty$
- (c)  $T(x) = \left(1 - \frac{xh}{k}\right) T_\infty$
- (d)  $T(x) = (L-x) T_\infty$
- (e)  $T(x) = T_\infty$

**2-159** A solar heat flux  $\dot{q}_s$  is incident on a sidewalk whose thermal conductivity is  $k$ , solar absorptivity is  $\alpha_s$ , and convective heat transfer coefficient is  $h$ . Taking the positive  $x$  direction to be towards the sky and disregarding radiation exchange with the surroundings surfaces, the correct boundary condition for this sidewalk surface is

- (a)  $-k \frac{dT}{dx} = \alpha_s \dot{q}_s$
- (b)  $-k \frac{dT}{dx} = h(T - T_\infty)$
- (c)  $-k \frac{dT}{dx} = h(T - T_\infty) - \alpha_s \dot{q}_s$
- (d)  $h(T - T_\infty) = \alpha_s \dot{q}_s$
- (e) None of them

**2-160** A plane wall of thickness  $L$  is subjected to convection at both surfaces with ambient temperature  $T_{\infty 1}$  and heat transfer coefficient  $h_1$  at inner surface, and corresponding  $T_{\infty 2}$  and  $h_2$  values at the outer surface. Taking the positive direction of  $x$  to be from the inner surface to the outer surface, the correct expression for the convection boundary condition is

- (a)  $k \frac{dT(0)}{dx} = h_1[T(0) - T_{\infty 1}]$
- (b)  $k \frac{dT(L)}{dx} = h_2[T(L) - T_{\infty 2}]$
- (c)  $-k \frac{dT(0)}{dx} = h_1[T_{\infty 1} - T_{\infty 2}]$
- (d)  $-k \frac{dT(L)}{dx} = h_2[T_{\infty 1} - T_{\infty 2}]$
- (e) None of them

**2-161** Consider steady one-dimensional heat conduction through a plane wall, a cylindrical shell, and a spherical shell of uniform thickness with constant thermophysical properties and no thermal energy generation. The geometry in which the variation of temperature in the direction of heat transfer will be linear is

- (a) plane wall
- (b) cylindrical shell
- (c) spherical shell
- (d) all of them
- (e) none of them

**2-162** The conduction equation boundary condition for an adiabatic surface with direction  $n$  being normal to the surface is

- (a)  $T = 0$
- (b)  $dT/dn = 0$
- (c)  $d^2T/dn^2 = 0$
- (d)  $d^3T/dn^3 = 0$
- (e)  $-k dT/dn = 1$

**2-163** The variation of temperature in a plane wall is determined to be  $T(x) = 52x + 25$  where  $x$  is in m and  $T$  is in °C. If the temperature at one surface is 38°C, the thickness of the wall is

- (a) 0.10 m
- (b) 0.20 m
- (c) 0.25 m
- (d) 0.40 m
- (e) 0.50 m

**2-164** The variation of temperature in a plane wall is determined to be  $T(x) = 110 - 60x$  where  $x$  is in m and  $T$  is in °C. If the thickness of the wall is 0.75 m, the temperature difference between the inner and outer surfaces of the wall is

- (a) 30°C
- (b) 45°C
- (c) 60°C
- (d) 75°C
- (e) 84°C

**2-165** The temperatures at the inner and outer surfaces of a 15-cm-thick plane wall are measured to be 40°C and 28°C, respectively. The expression for steady, one-dimensional variation of temperature in the wall is

- (a)  $T(x) = 28x + 40$
- (b)  $T(x) = -40x + 28$
- (c)  $T(x) = 40x + 28$
- (d)  $T(x) = -80x + 40$
- (e)  $T(x) = 40x - 80$

**2-166** The thermal conductivity of a solid depends upon the solid's temperature as  $k = aT + b$  where  $a$  and  $b$  are constants. The temperature in a planar layer of this solid as it conducts heat is given by

- (a)  $aT + b = x + C_2$
- (b)  $aT + b = C_1x^2 + C_2$
- (c)  $aT^2 + bT = C_1x + C_2$
- (d)  $aT^2 + bT = C_1x^2 + C_2$
- (e) None of them

**2-167** Hot water flows through a PVC ( $k = 0.092$  W/m·K) pipe whose inner diameter is 2 cm and outer diameter is 2.5 cm. The temperature of the interior surface of this pipe is 50°C and the temperature of the exterior surface is 20°C. The rate of heat transfer per unit of pipe length is

- (a) 77.7 W/m
- (b) 89.5 W/m
- (c) 98.0 W/m
- (d) 112 W/m
- (e) 168 W/m

**2-168** Heat is generated in a long 0.3-cm-diameter cylindrical electric heater at a rate of 180 W/cm<sup>3</sup>. The heat flux at the surface of the heater in steady operation is

- (a) 12.7 W/cm<sup>2</sup>
- (b) 13.5 W/cm<sup>2</sup>
- (c) 64.7 W/cm<sup>2</sup>
- (d) 180 W/cm<sup>2</sup>
- (e) 191 W/cm<sup>2</sup>

**2-169** Heat is generated uniformly in a 4-cm-diameter, 12-cm-long solid bar ( $k = 2.4$  W/m·K). The temperatures at the center and at the surface of the bar are measured to be 210°C and 45°C, respectively. The rate of heat generation within the bar is

- (a) 597 W
- (b) 760 W
- (c) 826 W
- (d) 928 W
- (e) 1020 W

**2-170** Heat is generated in a 10-cm-diameter spherical radioactive material whose thermal conductivity is 25 W/m·K

uniformly at a rate of  $15 \text{ W/cm}^3$ . If the surface temperature of the material is measured to be  $120^\circ\text{C}$ , the center temperature of the material during steady operation is

- (a)  $160^\circ\text{C}$
- (b)  $205^\circ\text{C}$
- (c)  $280^\circ\text{C}$
- (d)  $370^\circ\text{C}$
- (e)  $495^\circ\text{C}$

**2-171** Heat is generated in a 3-cm-diameter spherical radioactive material uniformly at a rate of  $15 \text{ W/cm}^3$ . Heat is dissipated to the surrounding medium at  $25^\circ\text{C}$  with a heat transfer coefficient of  $120 \text{ W/m}^2\cdot\text{K}$ . The surface temperature of the material in steady operation is

- (a)  $56^\circ\text{C}$
- (b)  $84^\circ\text{C}$
- (c)  $494^\circ\text{C}$
- (d)  $650^\circ\text{C}$
- (e)  $108^\circ\text{C}$

### Design and Essay Problems

**2-172** Write an essay on heat generation in nuclear fuel rods. Obtain information on the ranges of heat generation, the

variation of heat generation with position in the rods, and the absorption of emitted radiation by the cooling medium.

**2-173**  Write an interactive computer program to calculate the heat transfer rate and the value of temperature anywhere in the medium for steady one-dimensional heat conduction in a long cylindrical shell for any combination of specified temperature, specified heat flux, and convection boundary conditions. Run the program for five different sets of specified boundary conditions.

**2-174** Write an interactive computer program to calculate the heat transfer rate and the value of temperature anywhere in the medium for steady one-dimensional heat conduction in a spherical shell for any combination of specified temperature, specified heat flux, and convection boundary conditions. Run the program for five different sets of specified boundary conditions.

## STEADY HEAT CONDUCTION

### OBJECTIVES

When you finish studying this chapter, you should be able to:

- Understand the concept of thermal resistance and its limitations, and develop thermal resistance networks for practical heat conduction problems,
- Solve steady conduction problems that involve multilayer rectangular, cylindrical, or spherical geometries,
- Develop an intuitive understanding of thermal contact resistance, and circumstances under which it may be significant,
- Identify applications in which insulation may actually increase heat transfer,
- Analyze finned surfaces, and assess how efficiently and effectively fins enhance heat transfer, and
- Solve multidimensional practical heat conduction problems using conduction shape factors.

In heat transfer analysis, we are often interested in the rate of heat transfer through a medium under steady conditions and surface temperatures. Such problems can be solved easily without involving any differential equations by the introduction of the *thermal resistance concept* in an analogous manner to electrical circuit problems. In this case, the thermal resistance corresponds to electrical resistance, temperature difference corresponds to voltage, and the heat transfer rate corresponds to electric current.

We start this chapter with *one-dimensional steady heat conduction* in a plane wall, a cylinder, and a sphere, and develop relations for *thermal resistances* in these geometries. We also develop thermal resistance relations for convection and radiation conditions at the boundaries. We apply this concept to heat conduction problems in *multilayer* plane walls, cylinders, and spheres and generalize it to systems that involve heat transfer in two or three dimensions. We also discuss the *thermal contact resistance* and the *overall heat transfer coefficient* and develop relations for the critical radius of insulation for a cylinder and a sphere. Finally, we discuss steady heat transfer from *finned surfaces* and some complex geometries commonly encountered in practice through the use of *conduction shape factors*.

### 3–1 ■ STEADY HEAT CONDUCTION IN PLANE WALLS

Consider steady heat conduction through the walls of a house during a winter day. We know that heat is continuously lost to the outdoors through the wall. We intuitively feel that heat transfer through the wall is in the *normal direction* to the wall surface, and no significant heat transfer takes place in the wall in other directions (Fig. 3–1).

Recall that heat transfer in a certain direction is driven by the *temperature gradient* in that direction. There is no heat transfer in a direction in which there is no change in temperature. Temperature measurements at several locations on the inner or outer wall surface will confirm that a wall surface is nearly *isothermal*. That is, the temperatures at the top and bottom of a wall surface as well as at the right and left ends are almost the same. Therefore, there is no heat transfer through the wall from the top to the bottom, or from left to right, but there is considerable temperature difference between the inner and the outer surfaces of the wall, and thus significant heat transfer in the direction from the inner surface to the outer one.

The small thickness of the wall causes the temperature gradient in that direction to be large. Further, if the air temperatures in and outside the house remain constant, then heat transfer through the wall of a house can be modeled as *steady* and *one-dimensional*. The temperature of the wall in this case depends on one direction only (say the *x*-direction) and can be expressed as  $T(x)$ .

Noting that heat transfer is the only energy interaction involved in this case and there is no heat generation, the *energy balance* for the wall can be expressed as

$$\left( \begin{array}{l} \text{Rate of} \\ \text{heat transfer} \\ \text{into the wall} \end{array} \right) - \left( \begin{array}{l} \text{Rate of} \\ \text{heat transfer} \\ \text{out of the wall} \end{array} \right) = \left( \begin{array}{l} \text{Rate of change} \\ \text{of the energy} \\ \text{of the wall} \end{array} \right)$$

or

$$\dot{Q}_{\text{in}} - \dot{Q}_{\text{out}} = \frac{dE_{\text{wall}}}{dt} \quad (3-1)$$

But  $dE_{\text{wall}}/dt = 0$  for *steady* operation, since there is no change in the temperature of the wall with time at any point. Therefore, the rate of heat transfer into the wall must be equal to the rate of heat transfer out of it. In other words, *the rate of heat transfer through the wall must be constant*,  $\dot{Q}_{\text{cond, wall}} = \text{constant}$ .

Consider a plane wall of thickness  $L$  and average thermal conductivity  $k$ . The two surfaces of the wall are maintained at constant temperatures of  $T_1$  and  $T_2$ . For one-dimensional steady heat conduction through the wall, we have  $T(x)$ . Then Fourier's law of heat conduction for the wall can be expressed as

$$\dot{Q}_{\text{cond, wall}} = -kA \frac{dT}{dx} \quad (\text{W}) \quad (3-2)$$

where the rate of conduction heat transfer  $\dot{Q}_{\text{cond, wall}}$  and the wall area  $A$  are constant. Thus  $dT/dx = \text{constant}$ , which means that *the temperature through the wall varies linearly with  $x$* . That is, the temperature distribution in the wall under steady conditions is a *straight line* (Fig. 3–2).

**FIGURE 3–1**

Heat transfer through a wall is one-dimensional when the temperature of the wall varies in one direction only.

**FIGURE 3–2**

Under steady conditions, the temperature distribution in a plane wall is a straight line.

Separating the variables in the preceding equation and integrating from  $x = 0$ , where  $T(0) = T_1$ , to  $x = L$ , where  $T(L) = T_2$ , we get

$$\int_{x=0}^L \dot{Q}_{\text{cond, wall}} dx = - \int_{T=T_1}^{T_2} kA dT$$

Performing the integrations and rearranging gives

$$\dot{Q}_{\text{cond, wall}} = kA \frac{T_1 - T_2}{L} \quad (\text{W}) \quad (3-3)$$

which is identical to Eq. 1-21. Again, *the rate of heat conduction through a plane wall is proportional to the average thermal conductivity, the wall area, and the temperature difference, but is inversely proportional to the wall thickness*. Also, once the rate of heat conduction is available, the temperature  $T(x)$  at any location  $x$  can be determined by replacing  $T_2$  in Eq. 3-3 by  $T$ , and  $L$  by  $x$ .

## Thermal Resistance Concept

Equation 3-3 for heat conduction through a plane wall can be rearranged as

$$\dot{Q}_{\text{cond, wall}} = \frac{T_1 - T_2}{R_{\text{wall}}} \quad (\text{W}) \quad (3-4)$$

where

$$R_{\text{wall}} = \frac{L}{kA} \quad (\text{K/W}) \quad (3-5)$$

is the *thermal resistance* of the wall against heat conduction or simply the **conduction resistance** of the wall. Note that the thermal resistance of a medium depends on the *geometry* and the *thermal properties* of the medium. Note that thermal resistance can also be expressed as  $R_{\text{wall}} = \Delta T / \dot{Q}_{\text{cond, wall}}$ , which is the ratio of the driving potential  $\Delta T$  to the corresponding transfer rate  $\dot{Q}_{\text{cond, wall}}$ .

This equation for heat transfer is analogous to the relation for *electric current flow*  $I$ , expressed as

$$I = \frac{\mathbf{V}_1 - \mathbf{V}_2}{R_e} \quad (3-6)$$

where  $R_e = L/\sigma_e A$  is the *electric resistance* and  $\mathbf{V}_1 - \mathbf{V}_2$  is the *voltage difference* across the resistance ( $\sigma_e$  is the electrical conductivity). Thus, the *rate of heat transfer* through a layer corresponds to the *electric current*, the *thermal resistance* corresponds to *electrical resistance*, and the *temperature difference* corresponds to *voltage difference* across the layer (Fig. 3-3).

Consider convection heat transfer from a solid surface of area  $A_s$  and temperature  $T_s$  to a fluid whose temperature sufficiently far from the surface is  $T_\infty$ , with a convection heat transfer coefficient  $h$ . Newton's law of cooling for convection heat transfer rate  $\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty)$  can be rearranged as

$$\dot{Q}_{\text{conv}} = \frac{T_s - T_\infty}{R_{\text{conv}}} \quad (\text{W}) \quad (3-7)$$

**FIGURE 3-3**

Analogy between thermal and electrical resistance concepts.

where

$$R_{\text{conv}} = \frac{1}{hA_s} \quad (\text{K/W}) \quad (3-8)$$

is the *thermal resistance* of the surface against heat convection, or simply the **convection resistance** of the surface (Fig. 3-4). Note that when the convection heat transfer coefficient is very large ( $h \rightarrow \infty$ ), the convection resistance becomes *zero* and  $T_s \approx T_\infty$ . That is, the surface offers *no resistance to convection*, and thus it does not slow down the heat transfer process. This situation is approached in practice at surfaces where boiling and condensation occur. Also note that the surface does not have to be a plane surface. Equation 3-8 for convection resistance is valid for surfaces of any shape, provided that the assumption of  $h = \text{constant}$  and uniform is reasonable.

When the wall is surrounded by a gas, the *radiation effects*, which we have ignored so far, can be significant and may need to be considered. The rate of radiation heat transfer between a surface of emissivity  $\varepsilon$  and area  $A_s$  at temperature  $T_s$  and the surrounding surfaces at some average temperature  $T_{\text{surr}}$  can be expressed as

$$\dot{Q}_{\text{rad}} = \varepsilon\sigma A_s (T_s^4 - T_{\text{surr}}^4) = h_{\text{rad}} A_s (T_s - T_{\text{surr}}) = \frac{T_s - T_{\text{surr}}}{R_{\text{rad}}} \quad (\text{W}) \quad (3-9)$$

where

$$R_{\text{rad}} = \frac{1}{h_{\text{rad}} A_s} \quad (\text{K/W}) \quad (3-10)$$

is the *thermal resistance* of a surface against radiation, or the **radiation resistance**, and

$$h_{\text{rad}} = \frac{\dot{Q}_{\text{rad}}}{A_s(T_s - T_{\text{surr}})} = \varepsilon\sigma(T_s^2 + T_{\text{surr}}^2)(T_s + T_{\text{surr}}) \quad (\text{W/m}^2 \cdot \text{K}) \quad (3-11)$$

is the **radiation heat transfer coefficient**. Note that both  $T_s$  and  $T_{\text{surr}}$  must be in K in the evaluation of  $h_{\text{rad}}$ . The definition of the radiation heat transfer coefficient enables us to express radiation conveniently in an analogous manner to convection in terms of a temperature difference. But  $h_{\text{rad}}$  depends strongly on temperature while  $h_{\text{conv}}$  usually does not.

A surface exposed to the surrounding air involves convection and radiation simultaneously, and the total heat transfer at the surface is determined by adding (or subtracting, if in the opposite direction) the radiation and convection components. The convection and radiation resistances are parallel to each other, as shown in Fig. 3-5, and may cause some complication in the thermal resistance network. When  $T_{\text{surr}} \approx T_\infty$ , the radiation effect can properly be accounted for by replacing  $h$  in the convection resistance relation (Eq. 3-8) by

$$h_{\text{combined}} = h_{\text{conv}} + h_{\text{rad}} \quad (\text{W/m}^2 \cdot \text{K}) \quad (3-12)$$

where  $h_{\text{combined}}$  is the **combined heat transfer coefficient** discussed in Chapter 1. This way all complications associated with radiation are avoided.

**FIGURE 3-4**

Schematic for convection resistance at a surface.

**FIGURE 3-5**

Schematic for convection and radiation resistances at a surface.

**FIGURE 3–6**

The thermal resistance network for heat transfer through a plane wall subjected to convection on both sides, and the electrical analogy.

## Thermal Resistance Network

Now consider steady one-dimensional heat transfer through a plane wall of thickness  $L$ , area  $A$ , and thermal conductivity  $k$  that is exposed to convection on both sides to fluids at temperatures  $T_{\infty 1}$  and  $T_{\infty 2}$  with heat transfer coefficients  $h_1$  and  $h_2$ , respectively, as shown in Fig. 3–6. Assuming  $T_{\infty 2} < T_{\infty 1}$ , the variation of temperature will be as shown in the figure. Note that the temperature varies linearly in the wall, and asymptotically approaches  $T_{\infty 1}$  and  $T_{\infty 2}$  in the fluids as we move away from the wall.

Under steady conditions we have

$$\left( \begin{array}{l} \text{Rate of} \\ \text{heat convection} \end{array} \right) = \left( \begin{array}{l} \text{Rate of} \\ \text{heat conduction} \end{array} \right) = \left( \begin{array}{l} \text{Rate of} \\ \text{heat convection} \end{array} \right)$$

or

$$\dot{Q} = h_1 A(T_{\infty 1} - T_1) = kA \frac{T_1 - T_2}{L} = h_2 A(T_2 - T_{\infty 2}) \quad (3-13)$$

which can be rearranged as

$$\begin{aligned} \dot{Q} &= \frac{T_{\infty 1} - T_1}{1/h_1 A} = \frac{T_1 - T_2}{L/kA} = \frac{T_2 - T_{\infty 2}}{1/h_2 A} \\ &= \frac{T_{\infty 1} - T_1}{R_{\text{conv},1}} = \frac{T_1 - T_2}{R_{\text{wall}}} = \frac{T_2 - T_{\infty 2}}{R_{\text{conv},2}} \end{aligned} \quad (3-14)$$

Once the rate of heat transfer is calculated, Eq. 3–14 can also be used to determine the intermediate temperatures  $T_1$  or  $T_2$ . Adding the numerators and denominators yields (Fig. 3–7)

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} \quad (\text{W}) \quad (3-15)$$

where

$$R_{\text{total}} = R_{\text{conv},1} + R_{\text{wall}} + R_{\text{conv},2} = \frac{1}{h_1 A} + \frac{L}{kA} + \frac{1}{h_2 A} \quad (\text{K/W}) \quad (3-16)$$

Note that the heat transfer area  $A$  is constant for a plane wall, and the rate of heat transfer through a wall separating two media is equal to the overall temperature difference ( $T_{\infty 1} - T_{\infty 2}$ ) divided by the total thermal resistance between the media. Also note that the thermal resistances are in *series*, and the equivalent thermal resistance is determined by simply *adding* the individual resistances, just like the electrical resistances connected in series. Thus, the electrical analogy still applies. We summarize this as *the rate of steady heat transfer between two surfaces is equal to the temperature difference divided by the total thermal resistance between those two surfaces*.

Another observation that can be made from Eq. 3–15 is that the ratio of the temperature drop to the thermal resistance across any layer is constant, and thus the temperature drop across any layer is proportional to the thermal resistance of the layer. The larger the resistance, the larger the temperature drop. In fact, the equation  $\dot{Q} = \Delta T/R$  can be rearranged as

$$\Delta T = \dot{Q}R \quad (\text{°C}) \quad (3-17)$$

which indicates that the *temperature drop* across any layer is equal to the *rate of heat transfer* times the *thermal resistance* across that layer (Fig. 3–8). You may recall that this is also true for voltage drop across an electrical resistance when the electric current is constant.

It is sometimes convenient to express heat transfer through a medium in an analogous manner to Newton's law of cooling as

$$\dot{Q} = UA \Delta T \quad (\text{W}) \quad (3-18)$$

where  $U$  is the **overall heat transfer coefficient** with the unit  $\text{W}/\text{m}^2\cdot\text{K}$ . The overall heat transfer coefficient is usually used in heat transfer calculations associated with heat exchangers (Chapter 11). It is also used in heat transfer calculations through windows (Chapter 9), commonly referred to as U-factor. A comparison of Eqs. 3–15 and 3–18 reveals that

$$UA = \frac{1}{R_{\text{total}}} \quad (\text{W/K}) \quad (3-19)$$

Therefore, for a unit area, the overall heat transfer coefficient is equal to the inverse of the total thermal resistance.

Note that we do not need to know the surface temperatures of the wall in order to evaluate the rate of steady heat transfer through it. All we need to know is the convection heat transfer coefficients and the fluid temperatures

**FIGURE 3–7**  
A useful mathematical identity.

**FIGURE 3–8**  
The temperature drop across a layer is proportional to its thermal resistance.

on both sides of the wall. The *surface temperature* of the wall can be determined as described above using the thermal resistance concept, but by taking the surface at which the temperature is to be determined as one of the terminal surfaces. For example, once  $\dot{Q}$  is evaluated, the surface temperature  $T_1$  can be determined from

$$\dot{Q} = \frac{T_{\infty 1} - T_1}{R_{\text{conv}, 1}} = \frac{T_{\infty 1} - T_1}{1/h_1 A} \quad (3-20)$$

## Multilayer Plane Walls

In practice we often encounter plane walls that consist of several layers of different materials. The thermal resistance concept can still be used to determine the rate of steady heat transfer through such *composite* walls. As you may have already guessed, this is done by simply noting that the conduction resistance of each wall is  $L/kA$  connected in series, and using the electrical analogy. That is, by dividing the *temperature difference* between two surfaces at known temperatures by the *total thermal resistance* between them.

Consider a plane wall that consists of two layers (such as a brick wall with a layer of insulation). The rate of steady heat transfer through this two-layer composite wall can be expressed as (Fig. 3-9)

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} \quad (3-21)$$

where  $R_{\text{total}}$  is the *total thermal resistance*, expressed as

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv}, 1} + R_{\text{wall}, 1} + R_{\text{wall}, 2} + R_{\text{conv}, 2} \\ &= \frac{1}{h_1 A} + \frac{L_1}{k_1 A} + \frac{L_2}{k_2 A} + \frac{1}{h_2 A} \end{aligned} \quad (3-22)$$

**FIGURE 3-9**

The thermal resistance network for heat transfer through a two-layer plane wall subjected to convection on both sides.

$$\begin{aligned} R_{\text{conv}, 1} &= \frac{1}{h_1 A} & R_{\text{wall}, 1} &= \frac{L_1}{k_1 A} & R_{\text{wall}, 2} &= \frac{L_2}{k_2 A} & R_{\text{conv}, 2} &= \frac{1}{h_2 A} \end{aligned}$$

The subscripts 1 and 2 in the  $R_{\text{wall}}$  relations above indicate the first and the second layers, respectively. We could also obtain this result by following the approach already used for the single-layer case by noting that the rate of steady heat transfer  $\dot{Q}$  through a multilayer medium is constant, and thus it must be the same through each layer. Note from the thermal resistance network that the resistances are *in series*, and thus the *total thermal resistance* is simply the *arithmetic sum* of the individual thermal resistances in the path of heat transfer.

This result for the *two-layer* case is analogous to the *single-layer* case, except that an *additional resistance* is added for the *additional layer*. This result can be extended to plane walls that consist of *three or more layers* by adding an *additional resistance* for each *additional layer*.

Once  $\dot{Q}$  is known, an unknown surface temperature  $T_j$  at any surface or interface  $j$  can be determined from

$$\dot{Q} = \frac{T_i - T_j}{R_{\text{total}, i-j}} \quad (3-23)$$

where  $T_i$  is a *known* temperature at location  $i$  and  $R_{\text{total}, i-j}$  is the total thermal resistance between locations  $i$  and  $j$ . For example, when the fluid temperatures  $T_{\infty 1}$  and  $T_{\infty 2}$  for the two-layer case shown in Fig. 3-9 are available and  $\dot{Q}$  is calculated from Eq. 3-21, the interface temperature  $T_2$  between the two walls can be determined from (Fig. 3-10)

$$\dot{Q} = \frac{T_{\infty 1} - T_2}{R_{\text{conv}, 1} + R_{\text{wall}, 1}} = \frac{T_{\infty 1} - T_2}{\frac{1}{h_1 A} + \frac{L_1}{k_1 A}} \quad (3-24)$$

The temperature drop across a layer is easily determined from Eq. 3-17 by multiplying  $\dot{Q}$  by the thermal resistance of that layer.

The thermal resistance concept is widely used in practice because it is intuitively easy to understand and it has proven to be a powerful tool in the solution of a wide range of heat transfer problems. But its use is limited to systems through which the rate of heat transfer  $\dot{Q}$  remains *constant*; that is, to systems involving *steady* heat transfer with *no heat generation* (such as resistance heating or chemical reactions) within the medium.

### EXAMPLE 3-1 Heat Loss through a Wall

Consider a 3-m-high, 5-m-wide, and 0.3-m-thick wall whose thermal conductivity is  $k = 0.9 \text{ W/m}\cdot\text{K}$  (Fig. 3-11). On a certain day, the temperatures of the inner and the outer surfaces of the wall are measured to be  $16^\circ\text{C}$  and  $2^\circ\text{C}$ , respectively. Determine the rate of heat loss through the wall on that day.

$$\text{To find } T_1: \dot{Q} = \frac{T_{\infty 1} - T_1}{R_{\text{conv}, 1}}$$

$$\text{To find } T_2: \dot{Q} = \frac{T_{\infty 1} - T_2}{R_{\text{conv}, 1} + R_{\text{wall}, 1}}$$

$$\text{To find } T_3: \dot{Q} = \frac{T_3 - T_{\infty 2}}{R_{\text{conv}, 2}}$$

**FIGURE 3-10**

The evaluation of the surface and interface temperatures when  $T_{\infty 1}$  and  $T_{\infty 2}$  are given and  $\dot{Q}$  is calculated.

**FIGURE 3-11**

Schematic for Example 3-1.

**SOLUTION** The two surfaces of a wall are maintained at specified temperatures. The rate of heat loss through the wall is to be determined.

**Assumptions** 1 Heat transfer through the wall is steady since the surface temperatures remain constant at the specified values. 2 Heat transfer is one-dimensional since any significant temperature gradients exist in the direction from the indoors to the outdoors. 3 Thermal conductivity is constant.

**Properties** The thermal conductivity is given to be  $k = 0.9 \text{ W/m}\cdot\text{K}$ .

**Analysis** Noting that heat transfer through the wall is by conduction and the area of the wall is  $A = 3 \text{ m} \times 5 \text{ m} = 15 \text{ m}^2$ , the steady rate of heat transfer through the wall can be determined from Eq. 3–3 to be

$$\dot{Q} = kA \frac{T_1 - T_2}{L} = (0.9 \text{ W/m}\cdot\text{C})(15 \text{ m}^2) \frac{(16 - 2)^\circ\text{C}}{0.3 \text{ m}} = 630 \text{ W}$$

We could also determine the steady rate of heat transfer through the wall by making use of the thermal resistance concept from

$$\dot{Q} = \frac{\Delta T_{\text{wall}}}{R_{\text{wall}}}$$

where

$$R_{\text{wall}} = \frac{L}{kA} = \frac{0.3 \text{ m}}{(0.9 \text{ W/m}\cdot\text{C})(15 \text{ m}^2)} = 0.02222^\circ\text{C/W}$$

Substituting, we get

$$\dot{Q} = \frac{(16 - 2)^\circ\text{C}}{0.02222^\circ\text{C/W}} = 630 \text{ W}$$

**Discussion** This is the same result obtained earlier. Note that heat conduction through a plane wall with specified surface temperatures can be determined directly and easily without utilizing the thermal resistance concept. However, the thermal resistance concept serves as a valuable tool in more complex heat transfer problems, as you will see in the following examples. Also, the units  $\text{W/m}\cdot\text{C}$  and  $\text{W/m}\cdot\text{K}$  for thermal conductivity are equivalent, and thus interchangeable. This is also the case for  $^\circ\text{C}$  and  $\text{K}$  for temperature differences.

### EXAMPLE 3–2 Heat Loss through a Single-Pane Window

Consider a 0.8-m-high and 1.5-m-wide glass window with a thickness of 8 mm and a thermal conductivity of  $k = 0.78 \text{ W/m}\cdot\text{K}$ . Determine the steady rate of heat transfer through this glass window and the temperature of its inner surface for a day during which the room is maintained at  $20^\circ\text{C}$  while the temperature of the outdoors is  $-10^\circ\text{C}$ . Take the heat transfer coefficients on the inner and outer surfaces of the window to be  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 40 \text{ W/m}^2\cdot\text{K}$ , which includes the effects of radiation.

**SOLUTION** Heat loss through a window glass is considered. The rate of heat transfer through the window and the inner surface temperature are to be determined.

**Assumptions** 1 Heat transfer through the window is steady since the surface temperatures remain constant at the specified values. 2 Heat transfer through the wall is one-dimensional since any significant temperature gradients exist in the direction from the indoors to the outdoors. 3 Thermal conductivity is constant.

**Properties** The thermal conductivity is given to be  $k = 0.78 \text{ W/m}\cdot\text{K}$ .

**Analysis** This problem involves conduction through the glass window and convection at its surfaces, and can best be handled by making use of the thermal resistance concept and drawing the thermal resistance network, as shown in Fig. 3-12. Noting that the area of the window is  $A = 0.8 \text{ m} \times 1.5 \text{ m} = 1.2 \text{ m}^2$ , the individual resistances are evaluated from their definitions to be

$$R_i = R_{\text{conv}, 1} = \frac{1}{h_1 A} = \frac{1}{(10 \text{ W/m}^2\cdot\text{K})(1.2 \text{ m}^2)} = 0.08333^\circ\text{C}/\text{W}$$

$$R_{\text{glass}} = \frac{L}{kA} = \frac{0.008 \text{ m}}{(0.78 \text{ W/m}\cdot\text{K})(1.2 \text{ m}^2)} = 0.00855^\circ\text{C}/\text{W}$$

$$R_o = R_{\text{conv}, 2} = \frac{1}{h_2 A} = \frac{1}{(40 \text{ W/m}^2\cdot\text{K})(1.2 \text{ m}^2)} = 0.02083^\circ\text{C}/\text{W}$$

Noting that all three resistances are in series, the total resistance is

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv}, 1} + R_{\text{glass}} + R_{\text{conv}, 2} = 0.08333 + 0.00855 + 0.02083 \\ &= 0.1127^\circ\text{C}/\text{W} \end{aligned}$$

Then the steady rate of heat transfer through the window becomes

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} = \frac{[20 - (-10)]^\circ\text{C}}{0.1127^\circ\text{C}/\text{W}} = 266 \text{ W}$$

Knowing the rate of heat transfer, the inner surface temperature of the window glass can be determined from

$$\begin{aligned} \dot{Q} &= \frac{T_{\infty 1} - T_1}{R_{\text{conv}, 1}} \longrightarrow T_1 = T_{\infty 1} - \dot{Q}R_{\text{conv}, 1} \\ &= 20^\circ\text{C} - (266 \text{ W})(0.08333^\circ\text{C}/\text{W}) \\ &= -2.2^\circ\text{C} \end{aligned}$$

**Discussion** Note that the inner surface temperature of the window glass is  $-2.2^\circ\text{C}$  even though the temperature of the air in the room is maintained at  $20^\circ\text{C}$ . Such low surface temperatures are highly undesirable since they cause the formation of fog or even frost on the inner surfaces of the glass when the humidity in the room is high.

### EXAMPLE 3-3 Heat Loss through Double-Pane Windows

Consider a 0.8-m-high and 1.5-m-wide double-pane window consisting of two 4-mm-thick layers of glass ( $k = 0.78 \text{ W/m}\cdot\text{K}$ ) separated by a 10-mm-wide stagnant air space ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ). Determine the steady rate of heat

FIGURE 3-12

Schematic for Example 3-2.

FIGURE 3-13

Schematic for Example 3-3.

transfer through this double-pane window and the temperature of its inner surface for a day during which the room is maintained at 20°C while the temperature of the outdoors is -10°C. Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 40 \text{ W/m}^2\cdot\text{K}$ , which includes the effects of radiation.

**SOLUTION** A double-pane window is considered. The rate of heat transfer through the window and the inner surface temperature are to be determined.

**Analysis** This example problem is identical to the previous one except that the single 8-mm-thick window glass is replaced by two 4-mm-thick glasses that enclose a 10-mm-wide stagnant air space. Therefore, the thermal resistance network of this problem involves two additional conduction resistances corresponding to the two additional layers, as shown in Fig. 3-13. Noting that the area of the window is again  $A = 0.8 \text{ m} \times 1.5 \text{ m} = 1.2 \text{ m}^2$ , the individual resistances are evaluated from their definitions to be

$$R_i = R_{\text{conv}, 1} = \frac{1}{h_1 A} = \frac{1}{(10 \text{ W/m}^2\cdot\text{K})(1.2 \text{ m}^2)} = 0.08333^\circ\text{C/W}$$

$$R_1 = R_3 = R_{\text{glass}} = \frac{L_1}{k_1 A} = \frac{0.004 \text{ m}}{(0.78 \text{ W/m}\cdot\text{K})(1.2 \text{ m}^2)} = 0.00427^\circ\text{C/W}$$

$$R_2 = R_{\text{air}} = \frac{L_2}{k_2 A} = \frac{0.01 \text{ m}}{(0.026 \text{ W/m}\cdot\text{K})(1.2 \text{ m}^2)} = 0.3205^\circ\text{C/W}$$

$$R_o = R_{\text{conv}, 2} = \frac{1}{h_2 A} = \frac{1}{(40 \text{ W/m}^2\cdot\text{K})(1.2 \text{ m}^2)} = 0.02083^\circ\text{C/W}$$

Noting that all three resistances are in series, the total resistance is

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv}, 1} + R_{\text{glass}, 1} + R_{\text{air}} + R_{\text{glass}, 2} + R_{\text{conv}, 2} \\ &= 0.08333 + 0.00427 + 0.3205 + 0.00427 + 0.02083 \\ &= 0.4332^\circ\text{C/W} \end{aligned}$$

Then the steady rate of heat transfer through the window becomes

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} = \frac{[20 - (-10)]^\circ\text{C}}{0.4332^\circ\text{C/W}} = 69.2 \text{ W}$$

which is about one-fourth of the result obtained in the previous example. This explains the popularity of the double- and even triple-pane windows in cold climates. The drastic reduction in the heat transfer rate in this case is due to the large thermal resistance of the air layer between the glasses.

The inner surface temperature of the window in this case will be

$$T_1 = T_{\infty 1} - \dot{Q}R_{\text{conv}, 1} = 20^\circ\text{C} - (69.2 \text{ W})(0.08333^\circ\text{C/W}) = 14.2^\circ\text{C}$$

which is considerably higher than the  $-2.2^\circ\text{C}$  obtained in the previous example. Therefore, a double-pane window will rarely get fogged. A double-pane window will also reduce the heat gain in summer, and thus reduce the air-conditioning costs.

**FIGURE 3-14**

Temperature distribution and heat flow lines along two solid plates pressed against each other for the case of perfect and imperfect contact.

## 3-2 ▪ THERMAL CONTACT RESISTANCE

In the analysis of heat conduction through multilayer solids, we assumed “perfect contact” at the interface of two layers, and thus no temperature drop at the interface. This would be the case when the surfaces are perfectly smooth and they produce a perfect contact at each point. In reality, however, even flat surfaces that appear smooth to the eye turn out to be rather rough when examined under a microscope, as shown in Fig. 3-14, with numerous peaks and valleys. That is, a surface is *microscopically rough* no matter how smooth it appears to be.

When two such surfaces are pressed against each other, the peaks form good material contact but the valleys form voids filled with air in most cases. As a result, an interface contains numerous *air gaps* of varying sizes that act as *insulation* because of the low thermal conductivity of air. Thus, an interface offers some resistance to heat transfer, and this resistance for a unit interface area is called the **thermal contact resistance**,  $R_c$ . The value of  $R_c$  is determined experimentally using a setup like the one shown in Fig. 3-15, and as expected, there is considerable scatter of data because of the difficulty in characterizing the surfaces.

Consider heat transfer through two metal rods of cross-sectional area  $A$  that are pressed against each other. Heat transfer through the interface of these two rods is the sum of the heat transfers through the *solid contact spots* (solid-to-solid conduction) and the *gaps* (conduction and/or radiation across the gaps) in the noncontact areas (which is a major contributor to heat transfer) and can be expressed as

$$\dot{Q} = \dot{Q}_{\text{contact}} + \dot{Q}_{\text{gap}} \quad (3-25)$$

It can also be expressed in an analogous manner to Newton's law of cooling as

$$\dot{Q} = h_c A \Delta T_{\text{interface}} \quad (3-26)$$

**FIGURE 3-15**

A typical experimental setup for the determination of thermal contact resistance.

*From Song et al., 1993.*

where  $A$  is the apparent interface area (which is the same as the cross-sectional area of the rods) and  $\Delta T_{\text{interface}}$  is the effective temperature difference at the interface. The quantity  $h_c$ , which corresponds to the convection heat transfer coefficient, is called the **thermal contact conductance** and is expressed as

$$h_c = \frac{\dot{Q}/A}{\Delta T_{\text{interface}}} \quad (\text{W/m}^2\cdot\text{K}) \quad (3-27)$$

It is related to thermal contact resistance by

$$R_c = \frac{1}{h_c} = \frac{\Delta T_{\text{interface}}}{\dot{Q}/A} \quad (\text{m}^2\cdot\text{K/W}) \quad (3-28)$$

That is, thermal contact resistance is the inverse of thermal contact conductance. Usually, thermal contact conductance is reported in the literature, but the concept of thermal contact resistance serves as a better vehicle for explaining the effect of interface on heat transfer. Note that  $R_c$  represents thermal contact resistance for a *unit area*. The thermal resistance for the entire interface is obtained by dividing  $R_c$  by the apparent interface area  $A$ .

The thermal contact resistance can be determined from Eq. 3-28 by measuring the temperature drop at the interface and dividing it by the heat flux under steady conditions. The value of thermal contact resistance depends on the *surface roughness* and the *material properties* as well as the *temperature* and *pressure* at the interface and the *type of fluid* trapped at the interface. The situation becomes more complex when plates are fastened by bolts, screws, or rivets since the interface pressure in this case is nonuniform. The thermal contact resistance in that case also depends on the plate thickness, the bolt radius, and the size of the contact zone. Thermal contact resistance is observed to *decrease with decreasing surface roughness and increasing interface pressure*, as expected. Most experimentally determined values of the thermal contact resistance fall between 0.000005 and 0.0005 m<sup>2</sup>·K/W (the corresponding range of thermal contact conductance is 2000 to 200,000 W/m<sup>2</sup>·K).

When we analyze heat transfer in a medium consisting of two or more layers, the first thing we need to know is whether the thermal contact resistance is *significant* or not. We can answer this question by comparing the magnitudes of the thermal resistances of the layers with typical values of thermal contact resistance. For example, the thermal resistance of a 1-cm-thick layer of an insulating material for a unit surface area is

$$R_{c, \text{insulation}} = \frac{L}{k} = \frac{0.01 \text{ m}}{0.04 \text{ W/m}\cdot\text{K}} = 0.25 \text{ m}^2\cdot\text{K/W}$$

whereas for a 1-cm-thick layer of copper, it is

$$R_{c, \text{copper}} = \frac{L}{k} = \frac{0.01 \text{ m}}{386 \text{ W/m}\cdot\text{K}} = 0.000026 \text{ m}^2\cdot\text{K/W}$$

Comparing the values above with typical values of thermal contact resistance, we conclude that thermal contact resistance is significant and can even dominate the heat transfer for good heat conductors such as metals, but can be

disregarded for poor heat conductors such as insulations. This is not surprising since insulating materials consist mostly of air space just like the interface itself.

The thermal contact resistance can be minimized by applying a thermally conducting liquid called a *thermal grease* such as silicon oil on the surfaces before they are pressed against each other. This is commonly done when attaching electronic components such as power transistors to heat sinks. The thermal contact resistance can also be reduced by replacing the air at the interface by a *better conducting gas* such as helium or hydrogen, as shown in Table 3–1.

Another way to minimize the contact resistance is to insert a *soft metallic foil* such as tin, silver, copper, nickel, or aluminum between the two surfaces. Experimental studies show that the thermal contact resistance can be reduced by a factor of up to 7 by a metallic foil at the interface. For maximum effectiveness, the foils must be very thin. The effect of metallic coatings on thermal contact conductance is shown in Fig. 3–16 for various metal surfaces.

There is considerable uncertainty in the contact conductance data reported in the literature, and care should be exercised when using them. In Table 3–2 some experimental results are given for the contact conductance between similar and dissimilar metal surfaces for use in preliminary design calculations. Note that the *thermal contact conductance* is highest (and thus the contact resistance is lowest) for *soft metals with smooth surfaces at high pressure*.

#### EXAMPLE 3–4 Equivalent Thickness for Contact Resistance

The thermal contact conductance at the interface of two 1-cm-thick aluminum plates is measured to be 11,000 W/m<sup>2</sup>·K. Determine the thickness of the aluminum plate whose thermal resistance is equal to the thermal resistance of the interface between the plates (Fig. 3–17).

**SOLUTION** The thickness of the aluminum plate whose thermal resistance is equal to the thermal contact resistance is to be determined.

**Properties** The thermal conductivity of aluminum at room temperature is  $k = 237 \text{ W/m}\cdot\text{K}$  (Table A–3).

**Analysis** Noting that thermal contact resistance is the inverse of thermal contact conductance, the thermal contact resistance is

$$R_c = \frac{1}{h_c} = \frac{1}{11,000 \text{ W/m}^2\cdot\text{K}} = 0.909 \times 10^{-4} \text{ m}^2\cdot\text{K/W}$$

For a unit surface area, the thermal resistance of a flat plate is defined as

$$R = \frac{L}{k}$$

where  $L$  is the thickness of the plate and  $k$  is the thermal conductivity. Setting  $R = R_c$ , the equivalent thickness is determined from the relation above to be

$$L = kR_c = (237 \text{ W/m}\cdot\text{K})(0.909 \times 10^{-4} \text{ m}^2\cdot\text{K/W}) = 0.0215 \text{ m} = 2.15 \text{ cm}$$

TABLE 3–1

Thermal contact conductance for aluminum plates with different fluids at the interface for a surface roughness of 10  $\mu\text{m}$  and interface pressure of 1 atm (from Fried, 1969).

| Fluid at the interface | Contact conductance, $h_c$ , W/m <sup>2</sup> ·K |
|------------------------|--|
| Air                    | 3640   |

\*Divide the given values by 5.678 to convert to Btu/h·ft<sup>2</sup>·°F.

**Discussion** Note that the interface between the two plates offers as much resistance to heat transfer as a 2.15-cm-thick aluminum plate. It is interesting that the thermal contact resistance in this case is greater than the sum of the thermal resistances of both plates.

### EXAMPLE 3-5 Contact Resistance of Transistors

Four identical power transistors with aluminum casing are attached on one side of a 1-cm-thick 20-cm  $\times$  20-cm square copper plate ( $k = 386 \text{ W/m}\cdot\text{K}$ ) by screws that exert an average pressure of 6 MPa (Fig. 3-18). The base area of each transistor is  $8 \text{ cm}^2$ , and each transistor is placed at the center of a 10-cm  $\times$  10-cm quarter section of the plate. The interface roughness is estimated to be about  $1.5 \mu\text{m}$ . All transistors are covered by a thick Plexiglas layer, which is a poor conductor of heat, and thus all the heat generated at the junction of the transistor must be dissipated to the ambient at  $20^\circ\text{C}$  through the back surface of the copper plate. The combined convection/radiation heat transfer coefficient at the back surface can be taken to be  $25 \text{ W/m}^2\cdot\text{K}$ . If the case temperature

**FIGURE 3-17**

Schematic for Example 3-4.

of the transistor is not to exceed 70°C, determine the maximum power each transistor can dissipate safely, and the temperature jump at the case-plate interface.

**SOLUTION** Four identical power transistors are attached on a copper plate. For a maximum case temperature of 70°C, the maximum power dissipation and the temperature jump at the interface are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer can be approximated as being one-dimensional, although it is recognized that heat conduction in some parts of the plate will be two-dimensional since the plate area is much larger than the base area of the transistor. But the large thermal conductivity of copper will minimize this effect. 3 All the heat generated at the junction is dissipated through the back surface of the plate since the transistors are covered by a thick Plexiglas layer. 4 Thermal conductivities are constant.

**Properties** The thermal conductivity of copper is given to be  $k = 386 \text{ W/m}\cdot\text{K}$ . The contact conductance is obtained from Table 3–2 to be  $h_c = 42,000 \text{ W/m}^2\cdot\text{K}$ , which corresponds to copper-aluminum interface for the case of 1.17–1.4  $\mu\text{m}$  roughness and 5 MPa pressure, which is sufficiently close to what we have.

**Analysis** The contact area between the case and the plate is given to be  $8 \text{ cm}^2$ , and the plate area for each transistor is  $100 \text{ cm}^2$ . The thermal resistance network of this problem consists of three resistances in series (interface, plate, and convection), which are determined to be

$$R_{\text{interface}} = \frac{1}{h_c A_c} = \frac{1}{(42,000 \text{ W/m}^2\cdot\text{K})(8 \times 10^{-4} \text{ m}^2)} = 0.030^\circ\text{C/W}$$

$$R_{\text{plate}} = \frac{L}{kA} = \frac{0.01 \text{ m}}{(386 \text{ W/m}\cdot\text{K})(0.01 \text{ m}^2)} = 0.0026^\circ\text{C/W}$$

$$R_{\text{conv}} = \frac{1}{h_o A} = \frac{1}{(25 \text{ W/m}^2\cdot\text{K})(0.01 \text{ m}^2)} = 4.0^\circ\text{C/W}$$

The total thermal resistance is then

$$R_{\text{total}} = R_{\text{interface}} + R_{\text{plate}} + R_{\text{ambient}} = 0.030 + 0.0026 + 4.0 = 4.0326^\circ\text{C/W}$$

Note that the thermal resistance of a copper plate is very small and can be ignored altogether. Then the rate of heat transfer is determined to be

$$\dot{Q} = \frac{\Delta T}{R_{\text{total}}} = \frac{(70 - 20)^\circ\text{C}}{4.0326^\circ\text{C/W}} = 12.4 \text{ W}$$

Therefore, the power transistor should not be operated at power levels greater than 12.4 W if the case temperature is not to exceed 70°C.

The temperature jump at the interface is determined from

$$\Delta T_{\text{interface}} = \dot{Q} R_{\text{interface}} = (12.4 \text{ W})(0.030^\circ\text{C/W}) = 0.37^\circ\text{C}$$

which is not very large. Therefore, even if we eliminate the thermal contact resistance at the interface completely, we lower the operating temperature of the transistor in this case by less than 0.4°C.

**FIGURE 3–18**  
Schematic for Example 3–5.

**FIGURE 3-19**  
Thermal resistance network for two parallel layers.

### 3-3 ■ GENERALIZED THERMAL RESISTANCE NETWORKS

The *thermal resistance* concept or the *electrical analogy* can also be used to solve steady heat transfer problems that involve parallel layers or combined series-parallel arrangements. Although such problems are often two- or even three-dimensional, approximate solutions can be obtained by assuming one-dimensional heat transfer and using the thermal resistance network.

Consider the composite wall shown in Fig. 3-19, which consists of two parallel layers. The thermal resistance network, which consists of two parallel resistances, can be represented as shown in the figure. Noting that the total heat transfer is the sum of the heat transfers through each layer, we have

$$\dot{Q} = \dot{Q}_1 + \dot{Q}_2 = \frac{T_1 - T_2}{R_1} + \frac{T_1 - T_2}{R_2} = (T_1 - T_2) \left( \frac{1}{R_1} + \frac{1}{R_2} \right) \quad (3-29)$$

Utilizing electrical analogy, we get

$$\dot{Q} = \frac{T_1 - T_2}{R_{\text{total}}} \quad (3-30)$$

where

$$\frac{1}{R_{\text{total}}} = \frac{1}{R_1} + \frac{1}{R_2} \longrightarrow R_{\text{total}} = \frac{R_1 R_2}{R_1 + R_2} \quad (3-31)$$

since the resistances are in parallel.

Now consider the combined series-parallel arrangement shown in Fig. 3-20. The total rate of heat transfer through this composite system can again be expressed as

$$\dot{Q} = \frac{T_1 - T_{\infty}}{R_{\text{total}}} \quad (3-32)$$

where

$$R_{\text{total}} = R_{12} + R_3 + R_{\text{conv}} = \frac{R_1 R_2}{R_1 + R_2} + R_3 + R_{\text{conv}} \quad (3-33)$$

and

$$R_1 = \frac{L_1}{k_1 A_1} \quad R_2 = \frac{L_2}{k_2 A_2} \quad R_3 = \frac{L_3}{k_3 A_3} \quad R_{\text{conv}} = \frac{1}{h A_3} \quad (3-34)$$

Once the individual thermal resistances are evaluated, the total resistance and the total rate of heat transfer can easily be determined from the relations above.

The result obtained is somewhat approximate, since the surfaces of the third layer are probably not isothermal, and heat transfer between the first two layers is likely to occur.

Two assumptions commonly used in solving complex multidimensional heat transfer problems by treating them as one-dimensional (say, in the

**FIGURE 3-20**  
Thermal resistance network for combined series-parallel arrangement.

$x$ -direction) using the thermal resistance network are (1) any plane wall normal to the  $x$ -axis is *isothermal* (i.e., to assume the temperature to vary in the  $x$ -direction only) and (2) any plane parallel to the  $x$ -axis is *adiabatic* (i.e., to assume heat transfer to occur in the  $x$ -direction only). These two assumptions result in different resistance networks, and thus different (but usually close) values for the total thermal resistance and thus heat transfer. The actual result lies between these two values. In geometries in which heat transfer occurs predominantly in one direction, either approach gives satisfactory results.

### EXAMPLE 3–6 Heat Loss through a Composite Wall

A 3-m-high and 5-m-wide wall consists of long 16-cm  $\times$  22-cm cross section horizontal bricks ( $k = 0.72 \text{ W/m}\cdot\text{K}$ ) separated by 3-cm-thick plaster layers ( $k = 0.22 \text{ W/m}\cdot\text{K}$ ). There are also 2-cm-thick plaster layers on each side of the brick and a 3-cm-thick rigid foam ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ) on the inner side of the wall, as shown in Fig. 3–21. The indoor and the outdoor temperatures are  $20^\circ\text{C}$  and  $-10^\circ\text{C}$ , respectively, and the convection heat transfer coefficients on the inner and the outer sides are  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 25 \text{ W/m}^2\cdot\text{K}$ , respectively. Assuming one-dimensional heat transfer and disregarding radiation, determine the rate of heat transfer through the wall.

**SOLUTION** The composition of a composite wall is given. The rate of heat transfer through the wall is to be determined.

**Assumptions** 1 Heat transfer is steady since there is no indication of change with time. 2 Heat transfer can be approximated as being one-dimensional since it is predominantly in the  $x$ -direction. 3 Thermal conductivities are constant. 4 Heat transfer by radiation is negligible.

**Properties** The thermal conductivities are given to be  $k = 0.72 \text{ W/m}\cdot\text{K}$  for bricks,  $k = 0.22 \text{ W/m}\cdot\text{K}$  for plaster layers, and  $k = 0.026 \text{ W/m}\cdot\text{K}$  for the rigid foam.

**Analysis** There is a pattern in the construction of this wall that repeats itself every 25-cm distance in the vertical direction. There is no variation in the horizontal direction. Therefore, we consider a 1-m-deep and 0.25-m-high portion of the wall, since it is representative of the entire wall.

Assuming any cross section of the wall normal to the  $x$ -direction to be *isothermal*, the thermal resistance network for the representative section of the wall becomes as shown in Fig. 3–21. The individual resistances are evaluated as:

$$R_i = R_{\text{conv}, 1} = \frac{1}{h_1 A} = \frac{1}{(10 \text{ W/m}^2\cdot\text{K})(0.25 \times 1 \text{ m}^2)} = 0.40^\circ\text{C/W}$$

$$R_1 = R_{\text{foam}} = \frac{L}{kA} = \frac{0.03 \text{ m}}{(0.026 \text{ W/m}\cdot\text{K})(0.25 \times 1 \text{ m}^2)} = 4.62^\circ\text{C/W}$$

$$R_2 = R_6 = R_{\text{plaster, side}} = \frac{L}{kA} = \frac{0.02 \text{ m}}{(0.22 \text{ W/m}\cdot\text{K})(0.25 \times 1 \text{ m}^2)} \\ = 0.36^\circ\text{C/W}$$

$$R_3 = R_5 = R_{\text{plaster, center}} = \frac{L}{kA} = \frac{0.16 \text{ m}}{(0.22 \text{ W/m}\cdot\text{K})(0.015 \times 1 \text{ m}^2)} \\ = 48.48^\circ\text{C/W}$$

**FIGURE 3–21**  
Schematic for Example 3–6.

$$R_4 = R_{\text{brick}} = \frac{L}{kA} = \frac{0.16 \text{ m}}{(0.72 \text{ W/m}\cdot\text{K})(0.22 \times 1 \text{ m}^2)} = 1.01^\circ\text{C/W}$$

$$R_o = R_{\text{conv}, 2} = \frac{1}{h_2 A} = \frac{1}{(25 \text{ W/m}^2\cdot\text{K})(0.25 \times 1 \text{ m}^2)} = 0.16^\circ\text{C/W}$$

The three resistances  $R_3$ ,  $R_4$ , and  $R_5$  in the middle are parallel, and their equivalent resistance is determined from

$$\frac{1}{R_{\text{mid}}} = \frac{1}{R_3} + \frac{1}{R_4} + \frac{1}{R_5} = \frac{1}{48.48} + \frac{1}{1.01} + \frac{1}{48.48} = 1.03 \text{ W/}^\circ\text{C}$$

which gives

$$R_{\text{mid}} = 0.97^\circ\text{C/W}$$

Now all the resistances are in series, and the total resistance is

$$\begin{aligned} R_{\text{total}} &= R_i + R_1 + R_2 + R_{\text{mid}} + R_6 + R_o \\ &= 0.40 + 4.62 + 0.36 + 0.97 + 0.36 + 0.16 \\ &= 6.87^\circ\text{C/W} \end{aligned}$$

Then the steady rate of heat transfer through the wall becomes

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} = \frac{[20 - (-10)]^\circ\text{C}}{6.87^\circ\text{C/W}} = 4.37 \text{ W} \quad (\text{per } 0.25 \text{ m}^2 \text{ surface area})$$

or  $4.37/0.25 = 17.5 \text{ W per m}^2 \text{ area}$ . The total area of the wall is  $A = 3 \text{ m} \times 5 \text{ m} = 15 \text{ m}^2$ . Then the rate of heat transfer through the entire wall becomes

$$\dot{Q}_{\text{total}} = (17.5 \text{ W/m}^2)(15 \text{ m}^2) = \mathbf{263 \text{ W}}$$

Of course, this result is approximate, since we assumed the temperature within the wall to vary in one direction only and ignored any temperature change (and thus heat transfer) in the other two directions.

**Discussion** In the above solution, we assumed the temperature at any cross section of the wall normal to the  $x$ -direction to be *isothermal*. We could also solve this problem by going to the other extreme and assuming the surfaces parallel to the  $x$ -direction to be *adiabatic*. The thermal resistance network in this case will be as shown in Fig. 3–22. By following the approach outlined above, the total thermal resistance in this case is determined to be  $R_{\text{total}} = 6.97^\circ\text{C/W}$ , which is very close to the value  $6.85^\circ\text{C/W}$  obtained before. Thus either approach gives roughly the same result in this case. This example demonstrates that either approach can be used in practice to obtain satisfactory results.

**FIGURE 3-22**

Alternative thermal resistance network for Example 3–6 for the case of surfaces parallel to the primary direction of heat transfer being adiabatic.

### 3-4 ■ HEAT CONDUCTION IN CYLINDERS AND SPHERES

Consider steady heat conduction through a hot-water pipe. Heat is continuously lost to the outdoors through the wall of the pipe, and we intuitively feel that heat transfer through the pipe is in the normal direction to the pipe surface and no significant heat transfer takes place in the pipe in other directions (Fig. 3-23). The wall of the pipe, whose thickness is rather small, separates two fluids at different temperatures, and thus the temperature gradient in the radial direction is relatively large. Further, if the fluid temperatures inside and outside the pipe remain constant, then heat transfer through the pipe is *steady*. Thus heat transfer through the pipe can be modeled as *steady* and *one-dimensional*. The temperature of the pipe in this case depends on one direction only (the radial  $r$ -direction) and can be expressed as  $T = T(r)$ . The temperature is independent of the azimuthal angle or the axial distance. This situation is approximated in practice in long cylindrical pipes and spherical containers.

In *steady* operation, there is no change in the temperature of the pipe with time at any point. Therefore, the rate of heat transfer into the pipe must be equal to the rate of heat transfer out of it. In other words, heat transfer through the pipe must be constant,  $\dot{Q}_{\text{cond, cyl}} = \text{constant}$ .

Consider a long cylindrical layer (such as a circular pipe) of inner radius  $r_1$ , outer radius  $r_2$ , length  $L$ , and average thermal conductivity  $k$  (Fig. 3-24). The two surfaces of the cylindrical layer are maintained at constant temperatures  $T_1$  and  $T_2$ . There is no heat generation in the layer and the thermal conductivity is constant. For one-dimensional heat conduction through the cylindrical layer, we have  $T(r)$ . Then Fourier's law of heat conduction for heat transfer through the cylindrical layer can be expressed as

$$\dot{Q}_{\text{cond, cyl}} = -kA \frac{dT}{dr} \quad (\text{W}) \quad (3-35)$$

where  $A = 2\pi rL$  is the heat transfer area at location  $r$ . Note that  $A$  depends on  $r$ , and thus it *varies* in the direction of heat transfer. Separating the variables in the above equation and integrating from  $r = r_1$ , where  $T(r_1) = T_1$ , to  $r = r_2$ , where  $T(r_2) = T_2$ , gives

$$\int_{r=r_1}^{r_2} \frac{\dot{Q}_{\text{cond, cyl}}}{A} dr = - \int_{T=T_1}^{T_2} k dT \quad (3-36)$$

Substituting  $A = 2\pi rL$  and performing the integrations give

$$\dot{Q}_{\text{cond, cyl}} = 2\pi Lk \frac{T_1 - T_2}{\ln(r_2/r_1)} \quad (\text{W}) \quad (3-37)$$

since  $\dot{Q}_{\text{cond, cyl}} = \text{constant}$ . This equation can be rearranged as

$$\dot{Q}_{\text{cond, cyl}} = \frac{T_1 - T_2}{R_{\text{cyl}}} \quad (\text{W}) \quad (3-38)$$

where

$$R_{\text{cyl}} = \frac{\ln(r_2/r_1)}{2\pi Lk} = \frac{\text{ln}(\text{Outer radius}/\text{Inner radius})}{2\pi \times \text{Length} \times \text{Thermal conductivity}} \quad (3-39)$$

**FIGURE 3-23**

Heat is lost from a hot-water pipe to the air outside in the radial direction, and thus heat transfer from a long pipe is one-dimensional.

**RE 3-24**

A long cylindrical pipe (or spherical shell) with specified inner and outer surface temperatures  $T_1$  and  $T_2$ .

is the *thermal resistance* of the cylindrical layer against heat conduction, or simply the *conduction resistance* of the cylinder layer. Note that Eq. 3–37 is identical to Eq. 2–59 which was obtained by using the “standard” approach by first solving the heat conduction equation in cylindrical coordinates, Eq. 2–29, to obtain the temperature distribution, Eq. 2–58, and then using the Fourier’s law to obtain the heat transfer rate. The method used in obtaining Eq. 3–37 can be considered an “alternative” approach. However, it is restricted to one-dimensional steady heat conduction with no heat generation.

We can repeat the analysis for a *spherical layer* by taking  $A = 4\pi r^2$  and performing the integrations in Eq. 3–36. The result can be expressed as

$$\dot{Q}_{\text{cond, sph}} = \frac{T_1 - T_2}{R_{\text{sph}}} \quad (3-40)$$

where

**FIGURE 3-25**

The thermal resistance network for a cylindrical (or spherical) shell subjected to convection from both the inner and the outer sides.

is the *thermal resistance* of the spherical layer against heat conduction, or simply the *conduction resistance* of the spherical layer. Note also that Eq. 3–40 is identical to Eq. 2–61 which was obtained by solving the heat conduction equation in spherical coordinates.

Now consider steady one-dimensional heat transfer through a cylindrical or spherical layer that is exposed to convection on both sides to fluids at temperatures  $T_{\infty 1}$  and  $T_{\infty 2}$  with heat transfer coefficients  $h_1$  and  $h_2$ , respectively, as shown in Fig. 3–25. The thermal resistance network in this case consists of one conduction and two convection resistances in series, just like the one for the plane wall, and the rate of heat transfer under steady conditions can be expressed as

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} \quad (3-42)$$

where

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv}, 1} + R_{\text{cyl}} + R_{\text{conv}, 2} \\ &= \frac{1}{(2\pi r_1 L)h_1} + \frac{\ln(r_2/r_1)}{2\pi L k} + \frac{1}{(2\pi r_2 L)h_2} \end{aligned} \quad (3-43)$$

for a *cylindrical* layer, and

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv}, 1} + R_{\text{sph}} + R_{\text{conv}, 2} \\ &= \frac{1}{(4\pi r_1^2)h_1} + \frac{r_2 - r_1}{4\pi r_1 r_2 k} + \frac{1}{(4\pi r_2^2)h_2} \end{aligned} \quad (3-44)$$

for a *spherical* layer. Note that  $A$  in the convection resistance relation  $R_{\text{conv}} = 1/hA$  is the *surface area at which convection occurs*. It is equal to  $A = 2\pi rL$  for a cylindrical surface and  $A = 4\pi r^2$  for a spherical surface of radius  $r$ . Also note that the thermal resistances are in series, and thus the total thermal resistance is determined by simply adding the individual resistances, just like the electrical resistances connected in series.

## Multilayered Cylinders and Spheres

Steady heat transfer through multilayered cylindrical or spherical shells can be handled just like multilayered plane walls discussed earlier by simply adding an *additional resistance* in series for each *additional layer*. For example, the steady heat transfer rate through the three-layered composite cylinder of length  $L$  shown in Fig. 3–26 with convection on both sides can be expressed as

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} \quad (3-45)$$

where  $R_{\text{total}}$  is the *total thermal resistance*, expressed as

$$\begin{aligned} R_{\text{total}} &= R_{\text{conv},1} + R_{\text{cyl},1} + R_{\text{cyl},2} + R_{\text{cyl},3} + R_{\text{conv},2} \\ &= \frac{1}{h_1 A_1} + \frac{\ln(r_2/r_1)}{2\pi L k_1} + \frac{\ln(r_3/r_2)}{2\pi L k_2} + \frac{\ln(r_4/r_3)}{2\pi L k_3} + \frac{1}{h_2 A_4} \end{aligned} \quad (3-46)$$

where  $A_1 = 2\pi r_1 L$  and  $A_4 = 2\pi r_4 L$ . Equation 3–46 can also be used for a three-layered spherical shell by replacing the thermal resistances of cylindrical layers by the corresponding spherical ones. Again, note from the thermal resistance network that the resistances are in series, and thus the total thermal resistance is simply the *arithmetic sum* of the individual thermal resistances in the path of heat flow.

Once  $\dot{Q}$  is known, we can determine any intermediate temperature  $T_j$  by applying the relation  $\dot{Q} = (T_i - T_j)/R_{\text{total}, i-j}$  across any layer or layers such that  $T_i$  is a *known* temperature at location  $i$  and  $R_{\text{total}, i-j}$  is the total thermal resistance between locations  $i$  and  $j$  (Fig. 3–27). For example, once  $\dot{Q}$  has been calculated, the interface temperature  $T_2$  between the first and second cylindrical layers can be determined from

**FIGURE 3–26**

The thermal resistance network for heat transfer through a three-layered composite cylinder subjected to convection on both sides.

$$\begin{aligned}\dot{Q} &= \frac{T_{\infty 1} - T_1}{R_{\text{conv},1}} \\ &= \frac{T_{\infty 1} - T_2}{R_{\text{conv},1} + R_1} \\ &= \frac{T_{\infty 1} - T_2}{R_{\text{conv},1} + R_1 + R_2} \\ &= \frac{T_1 - T_3}{R_1 + R_2} \\ &= \frac{T_2 - T_3}{R_2} \\ &= \frac{T_2 - T_{\infty 2}}{R_2 + R_{\text{conv},2}} \\ &= \dots\end{aligned}$$

FIGURE 3-27

The ratio  $\Delta T/R$  across any layer is equal to  $\dot{Q}$ , which remains constant in one-dimensional steady conduction.

We could also calculate  $T_2$  from

$$\dot{Q} = \frac{T_2 - T_{\infty 2}}{R_2 + R_3 + R_{\text{conv},2}} = \frac{T_2 - T_{\infty 2}}{\frac{\ln(r_3/r_2)}{2\pi Lk_2} + \frac{\ln(r_4/r_3)}{2\pi Lk_3} + \frac{1}{h_o(2\pi r_4 L)}} \quad (3-48)$$

Although both relations give the same result, we prefer the first one since it involves fewer terms and thus less work.

The thermal resistance concept can also be used for *other geometries*, provided that the proper conduction resistances and the proper surface areas in convection resistances are used.

### EXAMPLE 3-7 Heat Transfer to a Spherical Container

A 3-m internal diameter spherical tank made of 2-cm-thick stainless steel ( $k = 15 \text{ W/m}\cdot\text{K}$ ) is used to store iced water at  $T_{\infty 1} = 0^\circ\text{C}$ . The tank is located in a room whose temperature is  $T_{\infty 2} = 22^\circ\text{C}$ . The walls of the room are also at  $22^\circ\text{C}$ . The outer surface of the tank and the surroundings is by natural convection and radiation. The convection heat transfer coefficients at the inner and the outer surfaces of the tank are  $h_1 = 80 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 10 \text{ W/m}^2\cdot\text{K}$ , respectively. Determine (a) the rate of heat transfer to the iced water in the tank and (b) the amount of ice at  $0^\circ\text{C}$  that melts during a 24-h period.

**SOLUTION** A spherical container filled with iced water is subjected to convection and radiation heat transfer at its outer surface. The rate of heat transfer and the amount of ice that melts per day are to be determined.

**Assumptions** 1 Heat transfer is steady since the specified thermal conditions at the boundaries do not change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the midpoint. 3 Thermal conductivity is constant.

**Properties** The thermal conductivity of steel is given to be  $k = 15 \text{ W/m}\cdot\text{K}$ . The heat of fusion of water at atmospheric pressure is  $h_{if} = 333.7 \text{ kJ/kg}$ . The outer surface of the tank is black and thus its emissivity is  $\epsilon = 1$ .

**Analysis** (a) The thermal resistance network for this problem is given in Fig. 3-28. Noting that the inner diameter of the tank is  $D_1 = 3 \text{ m}$  and the outer diameter is  $D_2 = 3.04 \text{ m}$ , the inner and outer surface areas of the tank are

$$\begin{aligned}A_1 &= \pi D_1^2 = \pi(3 \text{ m})^2 = 28.3 \text{ m}^2 \\ A_2 &= \pi D_2^2 = \pi(3.04 \text{ m})^2 = 29.0 \text{ m}^2\end{aligned}$$

Also, the radiation heat transfer coefficient is given by

$$h_{\text{rad}} = \epsilon\sigma(T_2^2 + T_{\infty 2}^2)(T_2 + T_{\infty 2})$$

But we do not know the outer surface temperature  $T_2$  of the tank, and thus we cannot calculate  $h_{\text{rad}}$ . Therefore, we need to assume a  $T_2$  value now and check

FIGURE 3-28

Schematic for Example 3-7.

the accuracy of this assumption later. We will repeat the calculations if necessary using a revised value for  $T_2$ .

We note that  $T_2$  must be between 0°C and 22°C, but it must be closer to 0°C, since the heat transfer coefficient inside the tank is much larger. Taking  $T_2 = 5^\circ\text{C} = 278 \text{ K}$ , the radiation heat transfer coefficient is determined to be

$$\begin{aligned} h_{\text{rad}} &= (1)(5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4)[(295 \text{ K})^2 + (278 \text{ K})^2][(295 + 278) \text{ K}] \\ &= 5.34 \text{ W/m}^2\cdot\text{K} = 5.34 \text{ W/m}^2\cdot^\circ\text{C} \end{aligned}$$

Then the individual thermal resistances become

$$R_i = R_{\text{conv}, 1} = \frac{1}{h_1 A_1} = \frac{1}{(80 \text{ W/m}^2\cdot\text{K})(28.3 \text{ m}^2)} = 0.000442^\circ\text{C/W}$$

$$R_1 = R_{\text{sphere}} = \frac{r_2 - r_1}{4\pi kr_1 r_2} = \frac{(1.52 - 1.50) \text{ m}}{4\pi (15 \text{ W/m}\cdot\text{K})(1.52 \text{ m})(1.50 \text{ m})}$$

$$= 0.000047^\circ\text{C/W}$$

$$R_o = R_{\text{conv}, 2} = \frac{1}{h_2 A_2} = \frac{1}{(10 \text{ W/m}^2\cdot\text{K})(29.0 \text{ m}^2)} = 0.00345^\circ\text{C/W}$$

$$R_{\text{rad}} = \frac{1}{h_{\text{rad}} A_2} = \frac{1}{(5.34 \text{ W/m}^2\cdot\text{K})(29.0 \text{ m}^2)} = 0.00646^\circ\text{C/W}$$

The two parallel resistances  $R_o$  and  $R_{\text{rad}}$  can be replaced by an equivalent resistance  $R_{\text{equiv}}$  determined from

$$\frac{1}{R_{\text{equiv}}} = \frac{1}{R_o} + \frac{1}{R_{\text{rad}}} = \frac{1}{0.00345} + \frac{1}{0.00646} = 444.7 \text{ W/}^\circ\text{C}$$

which gives

$$R_{\text{equiv}} = 0.00225^\circ\text{C/W}$$

Now all the resistances are in series, and the total resistance is

$$R_{\text{total}} = R_i + R_1 + R_{\text{equiv}} = 0.000442 + 0.000047 + 0.00225 = 0.00274^\circ\text{C/W}$$

Then the steady rate of heat transfer to the iced water becomes

$$\dot{Q} = \frac{T_{\infty 2} - T_{\infty 1}}{R_{\text{total}}} = \frac{(22 - 0)^\circ\text{C}}{0.00274^\circ\text{C/W}} = 8029 \text{ W} \quad (\text{or } \dot{Q} = 8.029 \text{ kJ/s})$$

To check the validity of our original assumption, we now determine the outer surface temperature from

$$\begin{aligned} \dot{Q} &= \frac{T_{\infty 2} - T_2}{R_{\text{equiv}}} \longrightarrow T_2 = T_{\infty 2} - \dot{Q} R_{\text{equiv}} \\ &= 22^\circ\text{C} - (8029 \text{ W})(0.00225^\circ\text{C/W}) = 4^\circ\text{C} \end{aligned}$$

which is sufficiently close to the 5°C assumed in the determination of the radiation heat transfer coefficient. Therefore, there is no need to repeat the calculations using 4°C for  $T_2$ .

(b) The total amount of heat transfer during a 24-h period is

$$\dot{Q} = \dot{Q} \Delta t = (8.029 \text{ kJ/s})(24 \times 3600 \text{ s}) = 693,700 \text{ kJ}$$

Noting that it takes 333.7 kJ of energy to melt 1 kg of ice at 0°C, the amount of ice that will melt during a 24-h period is

$$m_{\text{ice}} = \frac{\dot{Q}}{h_{if}} = \frac{693,700 \text{ kJ}}{333.7 \text{ kJ/kg}} = 2079 \text{ kg}$$

Therefore, about 2 metric tons of ice will melt in the tank every day.

**Discussion** An easier way to deal with combined convection and radiation at a surface when the surrounding medium and surfaces are at the same temperature is to add the radiation and convection heat transfer coefficients and to treat the result as the convection heat transfer coefficient. That is, to take  $h = 10 + 5.34 = 15.34 \text{ W/m}^2\text{-K}$  in this case. This way, we can ignore radiation since its contribution is accounted for in the convection heat transfer coefficient. The convection resistance of the outer surface in this case would be

$$R_{\text{combined}} = \frac{1}{h_{\text{combined}} A_2} = \frac{1}{(15.34 \text{ W/m}^2\text{-K})(29.0 \text{ m}^2)} = 0.00225^\circ\text{C/W}$$

which is identical to the value obtained for equivalent resistance for the parallel convection and the radiation resistances.

### EXAMPLE 3-8 Heat Loss through an Insulated Steam Pipe

Steam at  $T_{\infty 1} = 320^\circ\text{C}$  flows in a cast iron pipe ( $k = 80 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are  $D_1 = 5 \text{ cm}$  and  $D_2 = 5.5 \text{ cm}$ , respectively. The pipe is covered with 3-cm-thick glass wool insulation with  $k = 0.05 \text{ W/m}\cdot\text{K}$ . Heat is lost to the surroundings at  $T_{\infty 2} = 5^\circ\text{C}$  by natural convection and radiation, with a combined heat transfer coefficient of  $h_2 = 18 \text{ W/m}^2\text{-K}$ . Taking the heat transfer coefficient inside the pipe to be  $h_1 = 60 \text{ W/m}^2\text{-K}$ , determine the rate of heat loss from the steam per unit length of the pipe. Also determine the temperature drops across the pipe shell and the insulation.

**SOLUTION** A steam pipe covered with glass wool insulation is subjected to convection on its surfaces. The rate of heat transfer per unit length and the temperature drops across the pipe and the insulation are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no indication of any change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. 3 Thermal conductivities are constant. 4 The thermal contact resistance at the interface is negligible.

**Properties** The thermal conductivities are given to be  $k = 80 \text{ W/m}\cdot\text{K}$  for cast iron and  $k = 0.05 \text{ W/m}\cdot\text{K}$  for glass wool insulation.

**Analysis** The thermal resistance network for this problem involves four resistances in series and is given in Fig. 3–29. Taking  $L = 1 \text{ m}$ , the areas of the surfaces exposed to convection are determined to be

$$A_1 = 2\pi r_1 L = 2\pi(0.025 \text{ m})(1 \text{ m}) = 0.157 \text{ m}^2$$

$$A_3 = 2\pi r_3 L = 2\pi(0.0575 \text{ m})(1 \text{ m}) = 0.361 \text{ m}^2$$

Then the individual thermal resistances become

$$R_i = R_{\text{conv}, 1} = \frac{1}{h_1 A_1} = \frac{1}{(60 \text{ W/m}^2\cdot\text{K})(0.157 \text{ m}^2)} = 0.106^\circ\text{C/W}$$

$$R_1 = R_{\text{pipe}} = \frac{\ln(r_2/r_1)}{2\pi k_1 L} = \frac{\ln(2.75/2.5)}{2\pi(80 \text{ W/m}\cdot\text{K})(1 \text{ m})} = 0.0002^\circ\text{C/W}$$

$$R_2 = R_{\text{insulation}} = \frac{\ln(r_3/r_2)}{2\pi k_2 L} = \frac{\ln(5.75/2.75)}{2\pi(0.05 \text{ W/m}\cdot\text{K})(1 \text{ m})} = 2.35^\circ\text{C/W}$$

$$R_o = R_{\text{conv}, 2} = \frac{1}{h_2 A_3} = \frac{1}{(18 \text{ W/m}^2\cdot\text{K})(0.361 \text{ m}^2)} = 0.154^\circ\text{C/W}$$

Noting that all resistances are in series, the total resistance is determined to be

$$R_{\text{total}} = R_i + R_1 + R_2 + R_o = 0.106 + 0.0002 + 2.35 + 0.154 = 2.61^\circ\text{C/W}$$

Then the steady rate of heat loss from the steam becomes

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} = \frac{(320 - 5)^\circ\text{C}}{2.61^\circ\text{C/W}} = 121 \text{ W} \quad (\text{per m pipe length})$$

The heat loss for a given pipe length can be determined by multiplying the above quantity by the pipe length  $L$ .

The temperature drops across the pipe and the insulation are determined from Eq. 3–17 to be

$$\Delta T_{\text{pipe}} = \dot{Q} R_{\text{pipe}} = (121 \text{ W})(0.0002^\circ\text{C/W}) = 0.02^\circ\text{C}$$

$$\Delta T_{\text{insulation}} = \dot{Q} R_{\text{insulation}} = (121 \text{ W})(2.35^\circ\text{C/W}) = 284^\circ\text{C}$$

That is, the temperatures between the inner and the outer surfaces of the pipe differ by  $0.02^\circ\text{C}$ , whereas the temperatures between the inner and the outer surfaces of the insulation differ by  $284^\circ\text{C}$ .

**Discussion** Note that the thermal resistance of the pipe is too small relative to the other resistances and can be neglected without causing any significant error. Also note that the temperature drop across the pipe is practically zero, and thus the pipe can be assumed to be isothermal. The resistance to heat flow in insulated pipes is primarily due to insulation.

FIGURE 3–29

Schematic for Example 3–8.

### 3–5 • CRITICAL RADIUS OF INSULATION

We know that adding more insulation to a wall or to the attic always decreases heat transfer. The thicker the insulation, the lower the heat transfer rate. This is expected, since the heat transfer area  $A$  is constant, and adding insulation always increases the thermal resistance of the wall without increasing the convection resistance.

Adding insulation to a cylindrical pipe or a spherical shell, however, is a different matter. The additional insulation increases the conduction resistance

**FIGURE 3-30**

An insulated cylindrical pipe exposed to convection from the outer surface and the thermal resistance network associated with it.

**FIGURE 3-31**

The variation of heat transfer rate with the outer radius of the insulation  $r_2$  when  $r_1 < r_{\text{cr}}$ .

of the insulation layer but decreases the convection resistance of the surface because of the increase in the outer surface area for convection. The heat transfer from the pipe may increase or decrease, depending on which effect dominates.

Consider a cylindrical pipe of outer radius  $r_1$  whose outer surface temperature  $T_1$  is maintained constant (Fig. 3-30). The pipe is now insulated with a material whose thermal conductivity is  $k$  and outer radius is  $r_2$ . Heat is lost from the pipe to the surrounding medium at temperature  $T_\infty$ , with a convection heat transfer coefficient  $h$ . The rate of heat transfer from the insulated pipe to the surrounding air can be expressed as (Fig. 3-31)

$$\dot{Q} = \frac{T_1 - T_\infty}{R_{\text{ins}} + R_{\text{conv}}} = \frac{T_1 - T_\infty}{\frac{\ln(r_2/r_1)}{2\pi Lk} + \frac{1}{h(2\pi r_2 L)}} \quad (3-49)$$

The variation of  $\dot{Q}$  with the outer radius of the insulation  $r_2$  is plotted in Fig. 3-31. The value of  $r_2$  at which  $\dot{Q}$  reaches a maximum is determined from the requirement that  $d\dot{Q}/dr_2 = 0$  (zero slope). Performing the differentiation and solving for  $r_2$  yields the **critical radius of insulation** for a cylindrical body to be

$$r_{\text{cr, cylinder}} = \frac{k}{h} \quad (\text{m}) \quad (3-50)$$

Note that the critical radius of insulation depends on the thermal conductivity of the insulation  $k$  and the external convection heat transfer coefficient  $h$ . The rate of heat transfer from the cylinder increases with the addition of insulation for  $r_2 < r_{\text{cr}}$ , reaches a maximum when  $r_2 = r_{\text{cr}}$ , and starts to decrease for  $r_2 > r_{\text{cr}}$ . Thus, insulating the pipe may actually increase the rate of heat transfer from the pipe instead of decreasing it when  $r_2 < r_{\text{cr}}$ .

The important question to answer at this point is whether we need to be concerned about the critical radius of insulation when insulating hot-water pipes or even hot-water tanks. Should we always check and make sure that the outer radius of insulation sufficiently exceeds the critical radius before we install any insulation? Probably not, as explained here.

The value of the critical radius  $r_{\text{cr}}$  is the largest when  $k$  is large and  $h$  is small. Noting that the lowest value of  $h$  encountered in practice is about 5 W/m<sup>2</sup>·K for the case of natural convection of gases, and that the thermal conductivity of common insulating materials is about 0.05 W/m·K, the largest value of the critical radius we are likely to encounter is

$$r_{\text{cr, max}} = \frac{k_{\text{max, insulation}}}{h_{\text{min}}} \approx \frac{0.05 \text{ W/m}\cdot\text{K}}{5 \text{ W/m}^2\cdot\text{K}} = 0.01 \text{ m} = 1 \text{ cm}$$

This value would be even smaller when the radiation effects are considered. The critical radius would be much less in forced convection, often less than 1 mm, because of much larger  $h$  values associated with forced convection. Therefore, we can insulate hot-water or steam pipes freely without worrying about the possibility of increasing the heat transfer by insulating the pipes.

The radius of electric wires may be smaller than the critical radius. Therefore, the plastic electrical insulation may actually *enhance* the heat transfer

from electric wires and thus keep their steady operating temperatures at lower and thus safer levels.

The discussions above can be repeated for a sphere, and it can be shown in a similar manner that the critical radius of insulation for a spherical shell is

$$r_{\text{cr, sphere}} = \frac{2k}{h} \quad (3-51)$$

where  $k$  is the thermal conductivity of the insulation and  $h$  is the convection heat transfer coefficient on the outer surface.

### EXAMPLE 3-9 Heat Loss from an Insulated Electric Wire

A 3-mm-diameter and 5-m-long electric wire is tightly wrapped with a 2-mm-thick plastic cover whose thermal conductivity is  $k = 0.15 \text{ W/m}\cdot\text{K}$ . Electrical measurements indicate that a current of 10 A passes through the wire and there is a voltage drop of 8 V along the wire. If the insulated wire is exposed to a medium at  $T_\infty = 30^\circ\text{C}$  with a heat transfer coefficient of  $h = 12 \text{ W/m}^2\cdot\text{K}$ , determine the temperature at the interface of the wire and the plastic cover in steady operation. Also determine whether doubling the thickness of the plastic cover will increase or decrease this interface temperature.

**SOLUTION** An electric wire is tightly wrapped with a plastic cover. The interface temperature and the effect of doubling the thickness of the plastic cover on the interface temperature are to be determined.

**Assumptions** 1 Heat transfer is steady since there is no indication of any change with time. 2 Heat transfer is one-dimensional since there is thermal symmetry about the centerline and no variation in the axial direction. 3 Thermal conductivities are constant. 4 The thermal contact resistance at the interface is negligible. 5 Heat transfer coefficient incorporates the radiation effects, if any.

**Properties** The thermal conductivity of plastic is given to be  $k = 0.15 \text{ W/m}\cdot\text{K}$ .

**Analysis** Heat is generated in the wire and its temperature rises as a result of resistance heating. We assume heat is generated uniformly throughout the wire and is transferred to the surrounding medium in the radial direction. In steady operation, the rate of heat transfer becomes equal to the heat generated within the wire, which is determined to be

$$\dot{Q} = W_e = \mathbf{VI} = (8 \text{ V})(10 \text{ A}) = 80 \text{ W}$$

The thermal resistance network for this problem involves a conduction resistance for the plastic cover and a convection resistance for the outer surface in series, as shown in Fig. 3-32. The values of these two resistances are

$$A_2 = (2\pi r_2)L = 2\pi(0.0035 \text{ m})(5 \text{ m}) = 0.110 \text{ m}^2$$

$$R_{\text{conv}} = \frac{1}{hA_2} = \frac{1}{(12 \text{ W/m}^2\cdot\text{K})(0.110 \text{ m}^2)} = 0.76^\circ\text{C/W}$$

$$R_{\text{plastic}} = \frac{\ln(r_2/r_1)}{2\pi kL} = \frac{\ln(3.5/1.5)}{2\pi(0.15 \text{ W/m}\cdot\text{K})(5 \text{ m})} = 0.18^\circ\text{C/W}$$

FIGURE 3-32 Schematic for Example 3-9.

and therefore

$$R_{\text{total}} = R_{\text{plastic}} + R_{\text{conv}} = 0.76 + 0.18 = 0.94^{\circ}\text{C}/\text{W}$$

Then the interface temperature can be determined from

$$\begin{aligned} \dot{Q} &= \frac{T_1 - T_\infty}{R_{\text{total}}} \longrightarrow T_1 = T_\infty + \dot{Q}R_{\text{total}} \\ &= 30^{\circ}\text{C} + (80 \text{ W})(0.94^{\circ}\text{C}/\text{W}) = 105^{\circ}\text{C} \end{aligned}$$

Note that we did not involve the electrical wire directly in the thermal resistance network, since the wire involves heat generation.

To answer the second part of the question, we need to know the critical radius of insulation of the plastic cover. It is determined from Eq. 3–50 to be

$$r_{\text{cr}} = \frac{k}{h} = \frac{0.15 \text{ W/m}\cdot\text{K}}{12 \text{ W/m}^2\cdot\text{K}} = 0.0125 \text{ m} = 12.5 \text{ mm}$$

which is larger than the radius of the plastic cover. Therefore, increasing the thickness of the plastic cover will *enhance* heat transfer until the outer radius of the cover reaches 12.5 mm. As a result, the rate of heat transfer  $\dot{Q}$  will *increase* when the interface temperature  $T_1$  is held constant, or  $T_1$  will *decrease* when  $\dot{Q}$  is held constant, which is the case here.

**Discussion** It can be shown by repeating the calculations above for a 4-mm-thick plastic cover that the interface temperature drops to 90.6°C when the thickness of the plastic cover is doubled. It can also be shown in a similar manner that the interface reaches a minimum temperature of 83°C when the outer radius of the plastic cover equals the critical radius.

## 3–6 ▪ HEAT TRANSFER FROM FINNED SURFACES

The rate of heat transfer from a surface at a temperature  $T_s$  to the surrounding medium at  $T_\infty$  is given by Newton's law of cooling as

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty)$$

where  $A_s$  is the heat transfer surface area and  $h$  is the convection heat transfer coefficient. When the temperatures  $T_s$  and  $T_\infty$  are fixed by design considerations, as is often the case, there are *two ways* to increase the rate of heat transfer: to increase the *convection heat transfer coefficient*  $h$  or to increase the *surface area*  $A_s$ . Increasing  $h$  may require the installation of a pump or fan, or replacing the existing one with a larger one, but this approach may or may not be practical. Besides, it may not be adequate. The alternative is to increase the surface area by attaching to the surface *extended surfaces* called *fins* made of highly conductive materials such as aluminum. Finned surfaces are manufactured by extruding, welding, or wrapping a thin metal sheet on a surface. Fins enhance heat transfer from a surface by exposing a larger surface area to convection and radiation.

An interesting application of fins from about 150 million years ago, the Jurassic era, is shown in Fig. 3–33. The dinosaur stegosaurus lived during

**FIGURE 3–33**

Presumed cooling fins on dinosaur stegosaurus.

© Alamy RF

**FIGURE 3-34**

The thin plate fins of a car radiator greatly increase the rate of heat transfer to the air.

*Left: © Yunus A. Çengel, photo by James Kleiser, right: © McGraw-Hill Education / Christopher Kerrigan*

this era and it had two rows of big (and bizarre) bony plates down its back. For a long time, scientists thought that the plates were some kind of armor to protect the vegetarian from predators. We now know that a lot of blood flowed through the plates, and they may have acted like a car radiator. The heart pumped blood through the plates, and the plates acted like cooling fins to cool the blood down.

Finned surfaces are commonly used in practice to enhance heat transfer, and they often increase the rate of heat transfer from a surface severalfold. The car radiator shown in Fig. 3-34 is an example of a finned surface. The closely packed thin metal sheets attached to the hot-water tubes increase the surface area for convection and thus the rate of convection heat transfer from the tubes to the air many times. There are a variety of innovative fin designs available in the market, and they seem to be limited only by imagination (Fig. 3-35).

In the analysis of fins, we consider *steady* operation with *no heat generation* in the fin, and we assume the thermal conductivity  $k$  of the material to remain constant. We also assume the convection heat transfer coefficient  $h$  to be *constant* and *uniform* over the entire surface of the fin for convenience in the analysis. We recognize that the convection heat transfer coefficient  $h$ , in general, varies along the fin as well as its circumference, and its value at a point is a strong function of the *fluid motion* at that point. The value of  $h$  is usually much lower at the *fin base* than it is at the *fin tip* because the fluid is surrounded by solid surfaces near the base, which seriously disrupt its motion to the point of “suffocating” it, while the fluid near the fin tip has little contact with a solid surface and thus encounters little resistance to flow. Therefore, adding too many fins on a surface may actually decrease the overall heat transfer when the decrease in  $h$  offsets any gain resulting from the increase in the surface area.

## Fin Equation

Consider a volume element of a fin at location  $x$  having a length of  $\Delta x$ , cross-sectional area of  $A_c$ , and a perimeter of  $p$ , as shown in Fig. 3-36. Under steady conditions, the energy balance on this volume element can be expressed as

$$\left( \begin{array}{l} \text{Rate of heat} \\ \text{conduction into} \\ \text{the element at } x \end{array} \right) = \left( \begin{array}{l} \text{Rate of heat} \\ \text{conduction from the} \\ \text{element at } x + \Delta x \end{array} \right) + \left( \begin{array}{l} \text{Rate of heat} \\ \text{convection from} \\ \text{the element} \end{array} \right)$$

**FIGURE 3-35**

Some innovative fin designs.

**FIGURE 3-36**

Volume element of a fin at location  $x$  having a length of  $\Delta x$ , cross-sectional area of  $A_c$ , and perimeter of  $p$ .

or

$$\dot{Q}_{\text{cond},x} = \dot{Q}_{\text{cond},x+\Delta x} + \dot{Q}_{\text{conv}}$$

where

$$\dot{Q}_{\text{conv}} = h(p \Delta x)(T - T_{\infty})$$

Substituting and dividing by  $\Delta x$ , we obtain

$$\frac{\dot{Q}_{\text{cond},x+\Delta x} - \dot{Q}_{\text{cond},x}}{\Delta x} + hp(T - T_{\infty}) = 0 \quad (3-52)$$

Taking the limit as  $\Delta x \rightarrow 0$  gives

$$\frac{d\dot{Q}_{\text{cond}}}{dx} + hp(T - T_{\infty}) = 0 \quad (3-53)$$

From Fourier's law of heat conduction we have

$$\dot{Q}_{\text{cond}} = -kA_c \frac{dT}{dx} \quad (3-54)$$

where  $A_c$  is the cross-sectional area of the fin at location  $x$ . Substitution of this relation into Eq. 3-53 gives the differential equation governing heat transfer in fins,

$$\frac{d}{dx} \left( kA_c \frac{dT}{dx} \right) - hp(T - T_{\infty}) = 0 \quad (3-55)$$

In general, the cross-sectional area  $A_c$  and the perimeter  $p$  of a fin vary with  $x$ , which makes this differential equation difficult to solve. In the special case of *constant cross section* and *constant thermal conductivity*, the differential equation Eq. 3-55 reduces to

$$\frac{d^2T}{dx^2} - \frac{hp}{kA_c}(T - T_{\infty}) = 0 \quad \text{or} \quad \frac{d^2\theta}{dx^2} - m^2\theta = 0 \quad (3-56)$$

where

$$m^2 = \frac{hp}{kA_c} \quad (3-57)$$

and  $\theta = T - T_{\infty}$  is the *temperature excess*. At the fin base we have  $\theta_b = T_b - T_{\infty}$ .

Equation 3-56 is a linear, homogeneous, second-order differential equation with constant coefficients. A fundamental theory of differential equations states that such an equation has two linearly independent solution functions, and its general solution is the linear combination of those two solution functions. A careful examination of the differential equation reveals that subtracting a constant multiple of the solution function  $\theta$  from its second derivative yields zero. Thus we conclude that the function  $\theta$  and its second derivative must be *constant multiples* of each other. The only functions whose derivatives are constant multiples of the functions themselves are the *exponential functions* (or a linear combination of exponential functions such as sine and cosine hyperbolic functions). Therefore, the solution functions of the differential equation above are the exponential functions  $e^{-mx}$  or  $e^{mx}$  or constant multiples of them. This can be verified by direct substitution. For example, the second derivative of  $e^{-mx}$  is  $m^2 e^{-mx}$ , and its substitution into Eq. 3-56

yields zero. Therefore, the general solution of the differential equation Eq. 3-56 is

$$\theta(x) = C_1 e^{mx} + C_2 e^{-mx} \quad (3-58)$$

where  $C_1$  and  $C_2$  are arbitrary constants whose values are to be determined from the boundary conditions at the base and at the tip of the fin. Note that we need only two conditions to determine  $C_1$  and  $C_2$  uniquely.

The temperature of the plate to which the fins are attached is normally known in advance. Therefore, at the fin base we have a *specified temperature* boundary condition, expressed as

$$\text{Boundary condition at fin base:} \quad \theta(0) = \theta_b = T_b - T_\infty \quad (3-59)$$

At the fin tip we have several possibilities, including infinitely long fins, negligible heat loss (idealized as an adiabatic tip), specified temperature, and convection (Fig. 3-37). Next, we consider each case separately.

## 1 Infinitely Long Fin ( $T_{\text{fin tip}} = T_\infty$ )

For a sufficiently long fin of *uniform* cross section ( $A_c = \text{constant}$ ), the temperature of the fin at the fin tip approaches the environment temperature  $T_\infty$  and thus  $\theta$  approaches zero. That is,

$$\text{Boundary condition at fin tip:} \quad \theta(L) = T(L) - T_\infty = 0 \quad \text{as } L \rightarrow \infty$$

This condition is satisfied by the function  $e^{-mx}$ , but not by the other prospective solution function  $e^{mx}$  since it tends to infinity as  $x$  gets larger. Therefore, the general solution in this case will consist of a constant multiple of  $e^{-mx}$ . The value of the constant multiple is determined from the requirement that at the fin base where  $x = 0$  the value of  $\theta$  is  $\theta_b$ . Noting that  $e^{-mx} = e^0 = 1$ , the proper value of the constant is  $\theta_b$ , and the solution function we are looking for is  $\theta(x) = \theta_b e^{-mx}$ . This function satisfies the differential equation as well as the requirements that the solution reduce to  $\theta_b$  at the fin base and approach zero at the fin tip for large  $x$ . Noting that  $\theta = T - T_\infty$  and  $m = \sqrt{hp/kA_c}$ , the variation of temperature along the fin in this case can be expressed as

$$\text{Very long fin:} \quad \frac{T(x) - T_\infty}{T_b - T_\infty} = e^{-mx} = e^{-x\sqrt{hp/kA_c}} \quad (3-60)$$

Note that the temperature along the fin in this case decreases *exponentially* from  $T_b$  to  $T_\infty$ , as shown in Fig. 3-38. The steady rate of *heat transfer* from the entire fin can be determined from Fourier's law of heat conduction

$$\text{Very long fin:} \quad \dot{Q}_{\text{long fin}} = -kA_c \frac{dT}{dx} \Big|_{x=0} = \sqrt{hpkA_c} (T_b - T_\infty) \quad (3-61)$$

where  $p$  is the perimeter,  $A_c$  is the cross-sectional area of the fin, and  $x$  is the distance from the fin base. Alternatively, the rate of heat transfer from the fin could also be determined by considering heat transfer from a differential volume element of the fin and integrating it over the entire surface of the fin:

$$\dot{Q}_{\text{fin}} = \int_{A_{\text{fin}}} h[T(x) - T_\infty] dA_{\text{fin}} = \int_{A_{\text{fin}}} h\theta(x) dA_{\text{fin}} \quad (3-62)$$

1. Infinitely long fin
2. Negligible heat loss (adiabatic tip)
3. Specified temperature
4. Convection

**FIGURE 3-37**

Boundary conditions at the fin base and the fin tip.

$(p = \pi D, A_c = \pi D^2/4 \text{ for a cylindrical fin})$

**FIGURE 3-38**

A long circular fin of uniform cross section and the variation of temperature along it.

FIGURE 3-39

Under steady conditions, heat transfer from the exposed surfaces of the fin is equal to heat conduction to the fin at the base.

The two approaches described are equivalent and give the same result since, under steady conditions, the heat transfer from the exposed surfaces of the fin is equal to the heat transfer to the fin at the base (Fig. 3-39).

## 2 Negligible Heat Loss from the Fin Tip (Adiabatic fin tip, $\dot{Q}_{\text{fin tip}} = 0$ )

Fins are not likely to be so long that their temperature approaches the surrounding temperature at the tip. A more realistic situation is for heat transfer from the fin tip to be negligible since the heat transfer from the fin is proportional to its surface area, and the surface area of the fin tip is usually a negligible fraction of the total fin area. Then the fin tip can be assumed to be adiabatic, and the condition at the fin tip can be expressed as

$$\text{Boundary condition at fin tip: } \left. \frac{d\theta}{dx} \right|_{x=L} = 0 \quad (3-63)$$

The condition at the fin base remains the same as expressed in Eq. 3-59. The application of the boundary conditions given by Eqs. 3-59 and 3-63 on the general solution (Eq. 3-58) requires that  $\theta(0) = \theta_b = C_1 + C_2$  and  $mC_1 e^{mL} - mC_2 e^{-mL} = 0$ , respectively. Solving these two equations simultaneously for  $C_1$  and  $C_2$  yields  $C_1 = \theta_b / (1 + e^{2mL})$  and  $C_2 = \theta_b / (1 + e^{-2mL})$ . Substituting the relations for  $C_1$  and  $C_2$  into Eq. 3-58 and using the definition of the hyperbolic cosine function  $\cosh x = (e^x + e^{-x})/2$  gives the desired relation for the temperature distribution:

$$\text{Adiabatic fin tip: } \frac{T(x) - T_\infty}{T_b - T_\infty} = \frac{\cosh m(L-x)}{\cosh mL} \quad (3-64)$$

The rate of heat transfer from the fin can be determined again from Fourier's law of heat conduction:

$$\text{Adiabatic fin tip: } \dot{Q}_{\text{adiabatic tip}} = -kA_c \left. \frac{dT}{dx} \right|_{x=0} = \sqrt{hpkA_c} (T_b - T_\infty) \tanh mL \quad (3-65)$$

where the equation for the hyperbolic tangent function is

$$\tanh x = \sinh x / \cosh x = (e^x - e^{-x}) / (e^x + e^{-x}).$$

Note that the heat transfer relations for the very long fin and the fin with negligible heat loss at the tip differ by the factor  $\tanh mL$ , which approaches 1 as  $L$  becomes very large.

## 3 Specified Temperature ( $T_{\text{fin, tip}} = T_L$ )

In this case the temperature at the end of the fin (the fin tip) is fixed at a specified temperature  $T_L$ . This case could be considered as a generalization of the case of *Infinitely Long Fin* where the fin tip temperature was fixed at  $T_\infty$ . The condition at the fin tip for this case is

$$\text{Boundary condition at fin tip: } \theta(L) = \theta_L = T_L - T_\infty \quad (3-66)$$

The fin base boundary condition remains the same as given in Eq. 3-59. Applying the boundary conditions given by Eqs. 3-59 and 3-66 on the general solution (Eq. 3-58) gives, after some lengthy algebra and using the definition

of the hyperbolic sine function,  $\sinh x = (e^x - e^{-x})/2$ , the desired temperature distribution:

*Specified fin tip temperature:*

$$\frac{T(x) - T_\infty}{T_b - T_\infty} = \frac{[(T_L - T_\infty)/(T_b - T_\infty)] \sinh mx + \sinh m(L-x)}{\sinh mL} \quad (3-67)$$

Using the Fourier's law of heat conduction, the *rate of heat transfer* from the fin is

*Specified fin tip temperature:*

$$\begin{aligned} \dot{Q}_{\text{specified temp.}} &= -kA_c \frac{dT}{dx} \Big|_{x=0} \\ &= \sqrt{hpkA_c(T_b - T_\infty)} \frac{\cosh mL - [(T_L - T_\infty)/(T_b - T_\infty)]}{\sinh mL} \end{aligned} \quad (3-68)$$

Note that Eqs. 3-67 and 3-68 reduce to Eqs. 3-60 and 3-61 for the case of *infinitely long fin* ( $L \rightarrow \infty$ ).

## 4 Convection from Fin Tip

The fin tips, in practice, are exposed to the surroundings, and thus the proper boundary condition for the fin tip is convection that may also include the effects of radiation. Consider the case of convection only at the tip. The condition at the fin tip can be obtained from an energy balance at the fin tip ( $\dot{Q}_{\text{cond}} = \dot{Q}_{\text{conv}}$ ) That is,

$$\text{Boundary condition at fin tip: } -kA_c \frac{dT}{dx} \Big|_{x=L} = hA_c[T(L) - T_\infty] \quad (3-69)$$

The boundary condition at the fin base is Eq. 3-59, which is the same as the three previous cases. Substituting the two boundary conditions given by Eqs. 3-59 and 3-69 in the general solution (Eq. 3-58), it may be shown, after some lengthy manipulation that the temperature distribution is

$$\text{Convection from fin tip: } \frac{T(x) - T_\infty}{T_b - T_\infty} = \frac{\cosh m(L-x) + (h/mk) \sinh m(L-x)}{\cosh mL + (h/mk) \sinh mL} \quad (3-70)$$

The *rate of heat transfer* from the fin can be found by substituting the temperature gradient at the base of the fin, obtained from Eq. 3-70, into the Fourier's law of heat conduction. The result is

*Convection from fin tip:*

$$\begin{aligned} \dot{Q}_{\text{convection}} &= -kA_c \frac{dT}{dx} \Big|_{x=0} \\ &= \sqrt{hpkA_c(T_b - T_\infty)} \frac{\sinh mL + (h/mk) \cosh mL}{\cosh mL + (h/mk) \sinh mL} \end{aligned} \quad (3-71)$$

The solution to the general fin equation for the case of *convection from fin tip* is rather complex. An approximate, yet practical and accurate, way of accounting for the loss from the fin tip is to replace the *fin length*  $L$  in the relation for the *insulated tip* case by a **corrected fin length** defined as (Fig. 3-40)

*Corrected fin length:*

$$L_c = L + \frac{A_c}{p} \quad (3-72)$$

FIGURE 3-40

Corrected fin length  $L_c$  is defined such that heat transfer from a fin of length  $L_c$  with insulated tip is equal to heat transfer from the actual fin of length  $L$  with convection at the fin tip.

FIGURE 3-41

Fins enhance heat transfer from a surface by enhancing surface area.

FIGURE 3-42  
Ideal and actual temperature distribution along a fin.

where  $A_c$  is the cross-sectional area and  $p$  is the perimeter of the fin at the tip. Multiplying the relation above by the perimeter gives  $A_{\text{corrected}} = A_{\text{fin (lateral)}} + A_{\text{tip}}$ , which indicates that the fin area determined using the corrected length is equivalent to the sum of the lateral fin area plus the fin tip area.

The corrected length approximation gives very good results when the variation of temperature near the fin tip is small (which is the case when  $mL \geq 1$ ) and the heat transfer coefficient at the fin tip is about the same as that at the lateral surface of the fin. Therefore, *fins subjected to convection at their tips can be treated as fins with insulated tips by replacing the actual fin length by the corrected length in Eqs. 3-64 and 3-65.*

Using the proper relations for  $A_c$  and  $p$ , the corrected lengths for rectangular and cylindrical fins are easily determined to be

$$L_{c, \text{rectangular fin}} = L + \frac{t}{2} \quad \text{and} \quad L_{c, \text{cylindrical fin}} = L + \frac{D}{4}$$

where  $t$  is the thickness of the rectangular fins and  $D$  is the diameter of the cylindrical fins.

## Fin Efficiency

Consider the surface of a *plane wall* at temperature  $T_b$  exposed to a medium at temperature  $T_\infty$ . Heat is lost from the surface to the surrounding medium by convection with a heat transfer coefficient of  $h$ . Disregarding radiation or accounting for its contribution in the convection coefficient  $h$ , heat transfer from a surface area  $A_s$  is expressed as  $\dot{Q} = hA_s(T_s - T_\infty)$ .

Now let us consider a fin of constant cross-sectional area  $A_c = A_b$  and length  $L$  that is attached to the surface with a perfect contact (Fig. 3-41). This time heat is transferred from the surface to the fin by *conduction* and from the fin to the surrounding medium by *convection* with the same heat transfer coefficient  $h$ . The temperature of the fin is  $T_b$  at the fin base and gradually decreases toward the fin tip. Convection from the fin surface causes the temperature at any cross section to drop somewhat from the midsection toward the outer surfaces. However, the cross-sectional area of the fins is usually very small, and thus the temperature at any cross section can be considered to be uniform. Also, the fin tip can be assumed for convenience and simplicity to be adiabatic by using the corrected length for the fin instead of the actual length.

In the limiting case of *zero thermal resistance* or *infinite thermal conductivity* ( $k \rightarrow \infty$ ), the temperature of the fin is uniform at the base value of  $T_b$ . The heat transfer from the fin is *maximum* in this case and can be expressed as

$$\dot{Q}_{\text{fin, max}} = hA_{\text{fin}}(T_b - T_\infty) \quad (3-73)$$

In reality, however, the temperature of the fin drops along the fin, and thus the heat transfer from the fin is less because of the decreasing temperature difference  $T(x) - T_\infty$  toward the fin tip, as shown in Fig. 3-42. To account for the effect of this decrease in temperature on heat transfer, we define a **fin efficiency** as

$$\eta_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{fin, max}}} = \frac{\text{Actual heat transfer rate from the fin}}{\text{Ideal heat transfer rate from the fin if the entire fin were at base temperature}} \quad (3-74)$$

**TABLE 3-3**

Efficiency and surface areas of common fin configurations

**Straight rectangular fins**

$$m = \sqrt{2h/kt}$$

$$L_c = L + t/2$$

$$A_{\text{fin}} = 2wL_c$$

$$\eta_{\text{fin}} = \frac{\tanh mL_c}{mL_c}$$

**Straight triangular fins**

$$m = \sqrt{2h/kt}$$

$$A_{\text{fin}} = 2w\sqrt{L^2 + (t/2)^2}$$

$$\eta_{\text{fin}} = \frac{1}{mL} \frac{I_1(2mL)}{I_1(2mL)}$$

**Straight parabolic fins**

$$m = \sqrt{2h/kt}$$

$$A_{\text{fin}} = wL[C_1 + (L/t)\ln(t/L + C_1)]$$

$$C_1 = \sqrt{1 + (t/L)^2}$$

$$\eta_{\text{fin}} = \frac{2}{1 + \sqrt{(2mL)^2 + 1}}$$

**Circular fins of rectangular profile**

$$m = \sqrt{2h/kt}$$

$$r_{2c} = r_2 + t/2$$

$$A_{\text{fin}} = 2\pi(r_{2c}^2 - r_1^2)$$

$$\eta_{\text{fin}} = C_2 \frac{K_1(mr_1)I_1(mr_{2c}) - I_1(mr_1)K_1(mr_{2c})}{I_0(mr_1)K_1(mr_{2c}) + K_0(mr_1)I_1(mr_{2c})}$$

$$C_2 = \frac{2r_1/m}{r_{2c}^2 - r_1^2}$$

**Pin fins of rectangular profile**

$$m = \sqrt{4h/kD}$$

$$L_c = L + D/4$$

$$A_{\text{fin}} = \pi DL_c$$

$$\eta_{\text{fin}} = \frac{\tanh mL_c}{mL_c}$$

**Pin fins of triangular profile**

$$m = \sqrt{4h/kD}$$

$$A_{\text{fin}} = \frac{\pi D}{2}\sqrt{L^2 + (D/2)^2}$$

$$\eta_{\text{fin}} = \frac{2}{mL} \frac{I_0(2mL)}{I_1(2mL)}$$

$$I_2(x) = I_0(x) - (2/x)I_1(x) \text{ where } x = 2mL$$

**Pin fins of parabolic profile**

$$m = \sqrt{4h/kD}$$

$$A_{\text{fin}} = \frac{\pi L^3}{8D} [C_3 C_4 - \frac{L}{2D} \ln(2DC_4/L + C_3)]$$

$$C_3 = 1 + 2(D/L)^2$$

$$C_4 = \sqrt{1 + (D/L)^2}$$

$$\eta_{\text{fin}} = \frac{2}{1 + \sqrt{(2mL/3)^2 + 1}}$$

**Pin fins of parabolic profile (blunt tip)**

$$m = \sqrt{4h/kD}$$

$$A_{\text{fin}} = \frac{\pi D^4}{96L^2} \left\{ [16(L/D)^2 + 1]^{3/2} - 1 \right\}$$

$$\eta_{\text{fin}} = \frac{3}{2mL} \frac{I_2(4mL/3)}{I_0(4mL/3)}$$

\*Evaluated from EES using the mathematical functions Bessel\_I(x) and Bessel\_K(x)

or

$$\dot{Q}_{\text{fin}} = \eta_{\text{fin}} \dot{Q}_{\text{fin, max}} = \eta_{\text{fin}} h A_{\text{fin}} (T_b - T_\infty) \quad (3-75)$$

where  $A_{\text{fin}}$  is the total surface area of the fin. This relation enables us to determine the heat transfer from a fin when its efficiency is known. For the cases of constant cross section of *very long fins* and *fins with adiabatic tips*, the fin efficiency can be expressed as

$$\eta_{\text{long fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{fin, max}}} = \frac{\sqrt{hpkA_c}(T_b - T_\infty)}{hA_{\text{fin}}(T_b - T_\infty)} = \frac{1}{L} \sqrt{\frac{kA_c}{hp}} = \frac{1}{mL} \quad (3-76)$$

and

$$\eta_{\text{adiabatic tip}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{fin, max}}} = \frac{\sqrt{hpkA_c}(T_b - T_\infty) \tanh mL}{hA_{\text{fin}}(T_b - T_\infty)} = \frac{\tanh mL}{mL} \quad (3-77)$$

since  $A_{\text{fin}} = pL$  for fins with constant cross section. Equation 3-77 can also be used for fins subjected to convection provided that the fin length  $L$  is replaced by the corrected length  $L_c$ .

Table 3-3 provides fin efficiency relations for fins with uniform and non-uniform cross section. For fins with non-uniform profile, Eq. 3-56 is no longer valid and the general form of the differential equation governing heat transfer in fins of arbitrary shape, Eq. 3-55, must be used. For these cases the solution is no longer in the form of simple exponential or hyperbolic functions. The mathematical functions  $I$  and  $K$  that appear in some of these relations are the *modified Bessel functions*, and their values are given in Table 3-4. Efficiencies are plotted in Fig. 3-43 for fins on a *plain surface* and in Fig. 3-44 for *circular fins* of constant thickness. For most fins of constant thickness encountered in practice, the fin thickness  $t$  is too small relative to the fin length  $L$ , and thus the fin tip area is negligible.

Note that fins with triangular and parabolic profiles contain less material and are more efficient than the ones with rectangular profiles, and thus are more suitable for applications requiring minimum weight such as space applications.

An important consideration in the design of finned surfaces is the selection of the proper *fin length*  $L$ . Normally the *longer* the fin, the *larger* the heat transfer area and thus the *higher* the rate of heat transfer from the fin. But also the larger the fin, the bigger the mass, the higher the price, and the larger the fluid friction. Therefore, increasing the length of the fin beyond a certain value cannot be justified unless the added benefits outweigh the added cost. Also, the fin efficiency decreases with increasing fin length because of the decrease in fin temperature with length. Fin lengths that cause the fin efficiency to drop below 60 percent usually cannot be justified economically and should be avoided. The efficiency of most fins used in practice is above 90 percent.

## Fin Effectiveness

Fins are used to *enhance* heat transfer, and the use of fins on a surface cannot be recommended unless the enhancement in heat transfer justifies the added cost and complexity associated with the fins. In fact, there is no assurance that

**FIGURE 3-43**  
 Efficiency of straight fins of rectangular, triangular, and parabolic profiles.

**FIGURE 3-44**  
 Efficiency of annular fins of constant thickness  $t$ .

adding fins on a surface will *enhance* heat transfer. The performance of the fins is judged on the basis of the enhancement in heat transfer relative to the no-fin case. The performance of fins is expressed in terms of the *fin effectiveness*  $\varepsilon_{\text{fin}}$  defined as (Fig. 3-45)

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{no fin}}} = \frac{\dot{Q}_{\text{fin}}}{hA_b(T_b - T_\infty)} = \frac{\text{Heat transfer rate from the fin of base area } A_b}{\text{Heat transfer rate from the surface of area } A_b} \quad (3-78)$$

**FIGURE 3-45**

The effectiveness of a fin.

Hence,  $A_b$  is the cross-sectional area of the fin at the base and  $\dot{Q}_{\text{no fin}}$  represents the rate of heat transfer from this area if no fins are attached to the surface. An effectiveness of  $\varepsilon_{\text{fin}} = 1$  indicates that the addition of fins to the surface does not affect heat transfer at all. That is, heat conducted to the fin through the base area  $A_b$  is equal to the heat transferred from the same area  $A_b$  to the surrounding medium. An effectiveness of  $\varepsilon_{\text{fin}} < 1$  indicates that the fin actually acts as *insulation*, slowing down the heat transfer from the surface. This situation can occur when fins made of low thermal conductivity materials are used. An effectiveness of  $\varepsilon_{\text{fin}} > 1$  indicates that fins are *enhancing* heat transfer from the surface, as they should. However, the use of fins cannot be justified unless  $\varepsilon_{\text{fin}}$  is sufficiently larger than 1. Finned surfaces are designed on the basis of *maximizing* effectiveness for a specified cost or *minimizing* cost for a desired effectiveness.

Note that both the fin efficiency and fin effectiveness are related to the performance of the fin, but they are different quantities. However, they are related to each other by

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{no fin}}} = \frac{\dot{Q}_{\text{fin}}}{hA_b(T_b - T_\infty)} = \frac{\eta_{\text{fin}} hA_{\text{fin}}(T_b - T_\infty)}{hA_b(T_b - T_\infty)} = \frac{A_{\text{fin}}}{A_b} \eta_{\text{fin}} \quad (3-79)$$

Therefore, the fin effectiveness can be determined easily when the fin efficiency is known, or vice versa.

The rate of heat transfer from a sufficiently *long* fin of *uniform* cross section under steady conditions is given by Eq. 3-61. Substituting this relation into Eq. 3-78, the effectiveness of such a long fin is determined to be

$$\varepsilon_{\text{long fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{no fin}}} = \frac{\sqrt{hpkA_c}(T_b - T_\infty)}{hA_c(T_b - T_\infty)} = \sqrt{\frac{kp}{hA_c}} \quad (3-80)$$

since  $A_c = A_b$  in this case. We can draw several important conclusions from the fin effectiveness relation above for consideration in the design and selection of the fins:

- The *thermal conductivity*  $k$  of the fin material should be as high as possible. Thus it is no coincidence that fins are made from metals, with copper, aluminum, and iron being the most common ones. Perhaps the most widely used fins are made of aluminum because of its low cost and weight and its resistance to corrosion.
- The ratio of the *perimeter* to the *cross-sectional area* of the fin  $p/A_c$  should be as high as possible. This criterion is satisfied by *thin plate* fins and *slender pin* fins.
- The use of fins is *most effective* in applications involving a *low convection heat transfer coefficient*. Thus, the use of fins is more easily justified when the medium is a *gas* instead of a liquid and the heat transfer is by *natural convection* instead of by forced convection. Therefore, it is no coincidence that in liquid-to-gas heat exchangers such as the car radiator, fins are placed on the *gas* side.

When determining the rate of heat transfer from a finned surface, we must consider the *unfinned portion* of the surface as well as the *fins*. Therefore, the rate of heat transfer for a surface containing  $n$  fins can be expressed as

$$\begin{aligned}\dot{Q}_{\text{total, fin}} &= \dot{Q}_{\text{unfin}} + \dot{Q}_{\text{fin}} \\ &= hA_{\text{unfin}}(T_b - T_\infty) + \eta_{\text{fin}} hA_{\text{fin}}(T_b - T_\infty) \\ &= h(A_{\text{unfin}} + \eta_{\text{fin}} A_{\text{fin}})(T_b - T_\infty)\end{aligned}\quad (3-81)$$

We can also define an **overall effectiveness** for a finned surface as the ratio of the total heat transfer from the finned surface to the heat transfer from the same surface if there were no fins,

$$\varepsilon_{\text{fin, overall}} = \frac{\dot{Q}_{\text{total, fin}}}{\dot{Q}_{\text{total, no fin}}} = \frac{h(A_{\text{unfin}} + \eta_{\text{fin}} A_{\text{fin}})(T_b - T_\infty)}{hA_{\text{no fin}}(T_b - T_\infty)} = \frac{A_{\text{unfin}} + \eta_{\text{fin}} A_{\text{fin}}}{A_{\text{no fin}}}\quad (3-82)$$

where  $A_{\text{no fin}}$  is the area of the surface when there are no fins,  $A_{\text{fin}}$  is the total surface area of all the fins on the surface, and  $A_{\text{unfin}}$  is the area of the unfinned portion of the surface (Fig. 3-46). Note that the overall fin effectiveness depends on the fin density (number of fins per unit length) as well as the effectiveness of the individual fins. The overall effectiveness is a better measure of the performance of a finned surface than the effectiveness of the individual fins.

## Proper Length of a Fin

An important step in the design of a fin is the determination of the appropriate length of the fin once the fin material and the fin cross section are specified. You may be tempted to think that the longer the fin, the larger the surface area and thus the higher the rate of heat transfer. Therefore, for maximum heat transfer, the fin should be infinitely long. However, the temperature drops along the fin exponentially and reaches the environment temperature at some length. The part of the fin beyond this length does not contribute to heat transfer since it is at the temperature of the environment, as shown in Fig. 3-47. Therefore, designing such an “extra long” fin is out of the question since it results in material waste, excessive weight, and increased size and thus increased cost with no benefit in return (in fact, such a long fin will hurt performance since it will suppress fluid motion and thus reduce the convection heat transfer coefficient). Fins that are so long that the temperature approaches the environment temperature cannot be recommended either since the little increase in heat transfer at the tip region cannot justify the disproportionate increase in the weight and cost.

To get a sense of the proper length of a fin, we compare heat transfer from a fin of finite length to heat transfer from an infinitely long fin under the same conditions. The ratio of these two heat transfers is

$$\text{Heat transfer ratio: } \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{long fin}}} = \frac{\sqrt{hpkA_c}(T_b - T_\infty) \tanh mL}{\sqrt{hpkA_c}(T_b - T_\infty)} = \tanh mL\quad (3-83)$$

Using a hand calculator, the values of  $\tanh mL$  are evaluated for some values of  $mL$  and the results are given in Table 3-5. We observe from the table that heat transfer from a fin increases with  $mL$  almost linearly at first, but the curve reaches a plateau later and reaches a value for the infinitely long fin at about  $mL = 5$ . Therefore, a fin whose length is  $L = 5/m$  can be considered to be an infinitely long fin. We also observe that reducing the fin length by half in that case (from  $mL = 5$  to  $mL = 2.5$ ) causes a drop of just 1 percent in

$$\begin{aligned}A_{\text{no fin}} &= w \times H \\ A_{\text{unfin}} &= w \times H - 3 \times (t \times w) \\ A_{\text{fin}} &= 2 \times L \times w + t \times w \\ &\cong 2 \times L \times w \text{ (one fin)}\end{aligned}$$

FIGURE 3-46

Various surface areas associated with a rectangular surface with three fins.

FIGURE 3-47

Because of the gradual temperature drop along the fin, the region near the fin tip makes little or no contribution to heat transfer.

**TABLE 3–5**

The variation of heat transfer from a fin relative to that from an infinitely long fin

| $mL$ | $\frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{long fin}}} = \tanh mL$ |
|------|---|
| 0.1  | 0.100   |
| 0.2  | 0.197   |
| 0.5  | 0.462   |
| 1.0  | 0.762   |
| 1.5  | 0.905   |
| 2.0  | 0.964   |
| 2.5  | 0.987   |
| 3.0  | 0.995   |
| 4.0  | 0.999   |
| 5.0  | 1.000   |

heat transfer. We certainly would not hesitate sacrificing 1 percent in heat transfer performance in return for 50 percent reduction in the size and possibly the cost of the fin. In practice, a fin length that corresponds to about  $mL = 1$  will transfer 76.2 percent of the heat that can be transferred by an infinitely long fin, and thus it should offer a good compromise between heat transfer performance and the fin size.

A common approximation used in the analysis of fins is to assume the fin temperature to vary in one direction only (along the fin length) and the temperature variation along other directions is negligible. Perhaps you are wondering if this one-dimensional approximation is a reasonable one. This is certainly the case for fins made of thin metal sheets such as the fins on a car radiator, but we wouldn't be so sure for fins made of thick materials. Studies have shown that the error involved in one-dimensional fin analysis is negligible (less than about 1 percent) when

$$\frac{h\delta}{k} < 0.2$$

where  $\delta$  is the characteristic thickness of the fin, which is taken to be the plate thickness  $t$  for rectangular fins and the diameter  $D$  for cylindrical ones.

Specially designed finned surfaces called *heat sinks*, which are commonly used in the cooling of electronic equipment, involve one-of-a-kind complex geometries, as shown in Table 3–6. The heat transfer performance of heat sinks is usually expressed in terms of their *thermal resistances*  $R$  in °C/W, which is defined as

$$\dot{Q}_{\text{fin}} = \frac{T_b - T_\infty}{R} = hA_{\text{fin}} \eta_{\text{fin}} (T_b - T_\infty) \quad (3-84)$$

A small value of thermal resistance indicates a small temperature drop across the heat sink, and thus a high fin efficiency.

### EXAMPLE 3–10 Maximum Power Dissipation of a Transistor

Power transistors that are commonly used in electronic devices consume large amounts of electric power. The failure rate of electronic components increases almost exponentially with operating temperature. As a rule of thumb, the failure rate of electronic components is halved for each 10°C reduction in the junction operating temperature. Therefore, the operating temperature of electronic components is kept below a safe level to minimize the risk of failure.

The sensitive electronic circuitry of a power transistor at the junction is protected by its case, which is a rigid metal enclosure. Heat transfer characteristics of a power transistor are usually specified by the manufacturer in terms of the case-to-ambient thermal resistance, which accounts for both the natural convection and radiation heat transfers.

The case-to-ambient thermal resistance of a power transistor that has a maximum power rating of 10 W is given to be 20°C/W. If the case temperature of

(Continued on page 184)

**FIGURE 3-48**

Schematic for Example 3-10.

the transistor is not to exceed  $85^\circ\text{C}$ , determine the power at which this transistor can be operated safely in an environment at  $25^\circ\text{C}$ .

**SOLUTION** The maximum power rating of a transistor whose case temperature is not to exceed  $85^\circ\text{C}$  is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The transistor case is isothermal at  $85^\circ\text{C}$ .

**Properties** The case-to-ambient thermal resistance is given to be  $20^\circ\text{C}/\text{W}$ .

**Analysis** The power transistor and the thermal resistance network associated with it are shown in Fig. 3-48. We notice from the thermal resistance network that there is a single resistance of  $20^\circ\text{C}/\text{W}$  between the case at  $T_c = 85^\circ\text{C}$  and the ambient at  $T_\infty = 25^\circ\text{C}$ , and thus the rate of heat transfer is

$$\dot{Q} = \left( \frac{\Delta T}{R} \right)_{\text{case-ambient}} = \frac{T_c - T_\infty}{R_{\text{case-ambient}}} = \frac{(85 - 25)^\circ\text{C}}{20^\circ\text{C}/\text{W}} = 3 \text{ W}$$

Therefore, this power transistor should not be operated at power levels above 3 W if its case temperature is not to exceed  $85^\circ\text{C}$ .

**Discussion** This transistor can be used at higher power levels by attaching it to a heat sink (which lowers the thermal resistance by increasing the heat transfer surface area, as discussed in the next example) or by using a fan (which lowers the thermal resistance by increasing the convection heat transfer coefficient).

### EXAMPLE 3-11 Selecting a Heat Sink for a Transistor

A 60-W power transistor is to be cooled by attaching it to one of the commercially available heat sinks shown in Table 3-6. Select a heat sink that will allow the case temperature of the transistor not to exceed  $90^\circ\text{C}$  in the ambient air at  $30^\circ\text{C}$ .

**SOLUTION** A commercially available heat sink from Table 3-6 is to be selected to keep the case temperature of a transistor below  $90^\circ\text{C}$ .

**Assumptions** 1 Steady operating conditions exist. 2 The transistor case is isothermal at  $90^\circ\text{C}$ . 3 The contact resistance between the transistor and the heat sink is negligible.

**Analysis** The rate of heat transfer from a 60-W transistor at full power is  $\dot{Q} = 60 \text{ W}$ . The thermal resistance between the transistor attached to the heat sink and the ambient air for the specified temperature difference is determined to be

$$\dot{Q} = \frac{\Delta T}{R} \longrightarrow R = \frac{\Delta T}{\dot{Q}} = \frac{(90 - 30)^\circ\text{C}}{60 \text{ W}} = 1.0^\circ\text{C}/\text{W}$$

Therefore, the thermal resistance of the heat sink should be below  $1.0^\circ\text{C}/\text{W}$ . An examination of Table 3-6 reveals that the HS 5030, whose thermal resistance is  $0.9^\circ\text{C}/\text{W}$  in the vertical position, is the only heat sink that will meet this requirement.

**EXAMPLE 3–12 Heat Transfer from Fins of Variable Cross Section**

Aluminum pin fins of parabolic profile with blunt tips are attached on a plane wall with surface temperature of 200°C (Fig. 3–49). Each fin has a length of 20 mm and a base diameter of 5 mm. The fins are exposed to an ambient air condition of 25°C and the convection heat transfer coefficient is 50 W/m<sup>2</sup>·K. If the thermal conductivity of the fins is 240 W/m<sup>2</sup>·K, determine the efficiency, heat transfer rate, and effectiveness of each fin.

**SOLUTION** The efficiency, heat transfer rate, and effectiveness of a pin fin of parabolic profile with blunt tips are to be determined.

**Assumptions** 1 Heat conduction is steady and one-dimensional. 2 Thermal properties are constant. 3 Heat transfer by radiation is negligible.

**Properties** The thermal conductivity of the fin is given as 240 W/m<sup>2</sup>·K.

**Analysis** From Table 3–3, for pin fins of parabolic profile (blunt tip), we have

$$mL = \sqrt{\frac{4h}{kD}}L = \sqrt{\frac{4(50 \text{ W/m}^2\cdot\text{K})}{(240 \text{ W/m}\cdot\text{K})(0.005 \text{ m})}} (0.020 \text{ m}) = 0.2582$$

$$A_{\text{fin}} = \frac{\pi D^4}{96L^2} \left\{ \left[ 16 \left( \frac{L}{D} \right)^2 + 1 \right]^{3/2} - 1 \right\} = \frac{\pi (0.005 \text{ m})^4}{96(0.020 \text{ m})^2} \left\{ \left[ 16 \left( \frac{0.020 \text{ m}}{0.005 \text{ m}} \right)^2 + 1 \right]^{3/2} - 1 \right\} \\ = 2.106 \times 10^{-4} \text{ m}^2$$

$$\eta_{\text{fin}} = \frac{3}{2mL} \frac{I_1(4mL/3)}{I_0(4mL/3)} = \frac{3}{2(0.2582)} \frac{I_1[4(0.2582)/3]}{I_0[4(0.2582)/3]} = 5.8095 \frac{I_1[0.3443]}{I_0[0.3443]}$$

The values of the Bessel functions corresponding to  $x = 0.3443$  are determined from Table 3–4 to be  $I_0 = 1.0350$  and  $I_1 = 0.1716$ . Substituting, the fin efficiency is determined to be

$$\eta_{\text{fin}} = 5.8095 \frac{0.1716}{1.0350} = \mathbf{0.9632}$$

The heat transfer rate for a single fin is

$$\dot{Q}_{\text{fin}} = \eta_{\text{fin}} h A_{\text{fin}} (T_b - T_{\infty}) \\ = (0.9632)(50 \text{ W/m}^2\cdot\text{K})(2.106 \times 10^{-4} \text{ m}^2)(200 - 25)^\circ\text{C} = \mathbf{1.77 \text{ W}}$$

The fin effectiveness is

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{h A_b (T_b - T_{\infty})} = \frac{\dot{Q}_{\text{fin}}}{h (\pi D^2 / 4) (T_b - T_{\infty})} \\ = \frac{1.77 \text{ W}}{(50 \text{ W/m}^2\cdot\text{K}) [\pi (0.005 \text{ m})^2 / 4] (200 - 25)^\circ\text{C}} \\ = \mathbf{10.3}$$

That is, over a 10-fold increase in heat transfer is achieved by using a pin fin in this case.

**FIGURE 3–49**  
Schematic for Example 3–12.

**Discussion** The fin efficiency can be determined more accurately by avoiding the interpolation error by using an equation solver with built-in mathematical functions such as EES. Copying the line

$$\text{eta\_fin} = 3/(2*0.2582)*\text{Bessel\_J1}(4*0.2582/3)/\text{Bessel\_J0}(4*0.2582/3)$$

on a blank EES screen and hitting the ‘solve’ button gives the fin efficiency to be  $\eta_{\text{fin}} = 0.9855$ , which is about 2 percent higher than the result obtained above using the tables.

**FIGURE 3–50**

Schematic for Example 3–13.

**PtD** **EXAMPLE 3–13**

### Preventing Circuit Board Surface from Overheating

A 15-cm  $\times$  20-cm integrated circuit board is to be cooled by attaching 4-cm-long aluminum ( $k = 237 \text{ W/m}\cdot\text{K}$ ) fins on one side of it (Fig. 3–50). Each fin has a 2-mm  $\times$  2-mm square cross section. The surrounding ambient temperature is  $25^\circ\text{C}$  and the convection heat transfer coefficient on each fin surface is  $20 \text{ W/m}^2\cdot\text{K}$ . To prevent the circuit board from overheating, the upper surface of the circuit board needs to be at  $85^\circ\text{C}$  or cooler. Design a finned surface having the appropriate number of fins, with an overall effectiveness of 3 that can keep the circuit board surface from overheating.

**SOLUTION** In this example, the concepts of Prevention through Design (PtD) are applied in conjunction with the fin analysis. An integrated circuit board is to be cooled by attaching aluminum fins of square cross section on one side. The number of fins needed to keep the circuit board surface cooler than  $85^\circ\text{C}$ , while having an overall effectiveness of 3, is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat conduction is one-dimensional. 3 Heat transfer from the fin tips is negligible. 4 Fins are very long. 5 The heat transfer coefficient is constant and uniform over the entire fin surface. 6 The thermal properties of the fins are constant.

**Properties** The thermal conductivity of the aluminum fins is given to be  $k = 237 \text{ W/m}\cdot\text{K}$ .

**Analysis** Noting that the cross-sectional areas of the fins are constant, the efficiency of the square cross-section fins that are assumed to be very long with adiabatic tips can be determined to be

$$m = \sqrt{\frac{hp}{kA_c}} = \sqrt{\frac{4ha}{ka^2}} = \sqrt{\frac{4(20 \text{ W/m}^2\cdot\text{K})(0.02 \text{ m})}{(237 \text{ W/m}\cdot\text{K})(0.02 \text{ m})^2}} = 12.99 \text{ m}^{-1}$$

where  $a$  is the length of each side of the square fin.

$$\eta_{\text{fin}} = \frac{\tanh mL}{mL} = \frac{\tanh(12.99 \text{ m}^{-1} \times 0.04 \text{ m})}{12.99 \text{ m}^{-1} \times 0.04 \text{ m}} = 0.919$$

The finned and unfinned surface areas, and heat transfer rates from these areas are

$$\begin{aligned}
 A_{\text{fin}} &= n_{\text{fin}} \times 4 \times (0.002 \text{ m})(0.04 \text{ m}) = 0.00032n_{\text{fin}} \text{ m}^2 \\
 A_{\text{unfinned}} &= (0.15 \text{ m})(0.20 \text{ m}) - n_{\text{fin}}(0.002 \text{ m})(0.002 \text{ m}) \\
 &= 0.03 - 0.000004n_{\text{fin}} \text{ m}^2 \\
 \dot{Q}_{\text{finned}} &= \eta_{\text{fin}} \dot{Q}_{\text{fin,max}} = \eta_{\text{fin}} h A_{\text{fin}} (T_b - T_{\infty}) \\
 &= 0.919(20 \text{ W/m}^2 \cdot \text{K})(0.00032n_{\text{fin}} \text{ m}^2)(85 - 25)^\circ\text{C} \\
 &= 0.3529n_{\text{fin}} \text{ W} \\
 \dot{Q}_{\text{unfinned}} &= h A_{\text{unfinned}} (T_b - T_{\infty}) = (20 \text{ W/m}^2 \cdot \text{K})(0.03 - 0.000004n_{\text{fin}} \text{ m}^2)(85 - 25)^\circ\text{C} \\
 &= 36 - 0.0048n_{\text{fin}} \text{ W}
 \end{aligned}$$

Then the total heat transfer from the finned surface (circuit board) becomes

$$\dot{Q}_{\text{total,fin}} = \dot{Q}_{\text{finned}} + \dot{Q}_{\text{unfinned}} = 0.3529n_{\text{fin}} + 36 - 0.0048n_{\text{fin}} \text{ W}$$

The rate of heat transfer if there were no fins attached to the plate would be

$$\begin{aligned}
 A_{\text{no fin}} &= (0.15 \text{ m})(0.20 \text{ m}) = 0.03 \text{ m}^2 \\
 \dot{Q}_{\text{no fin}} &= h A_{\text{no fin}} (T_b - T_{\infty}) = (20 \text{ W/m}^2 \cdot \text{K})(0.03 \text{ m}^2)(85 - 25)^\circ\text{C} = 36 \text{ W}
 \end{aligned}$$

The number of fins can be determined from the overall fin effectiveness equation

$$\begin{aligned}
 \varepsilon_{\text{fin}} &= \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{no fin}}} \\
 3 &= \frac{0.3529n_{\text{fin}} + 36 - 0.0048n_{\text{fin}}}{36} \\
 n_{\text{fin}} &= 207
 \end{aligned}$$

**Discussion** To keep the circuit board surface from heating above  $85^\circ\text{C}$ , the finned surface having an overall effectiveness of 3 needs to have at least 207 fins. Number of fins on the circuit board may be reduced by using different fin material and geometry.

## 3–7 • BIOHEAT TRANSFER EQUATION

The study of heat transfer in biological systems is referred to as *bioheat transfer*. It is the study of heat transfer within the human body or external to the body. Bioheat transfer can be considered as a subfield of biomedical engineering with its foundation in the heat transfer engineering. Heat transfer within the human body, in particular in adverse environments, is an active area of research for the development of new medical treatments or devices to minimize the effects of the adverse conditions.

The transport of thermal energy in living tissues is a very complex process. It involves a multiple of mechanisms such as conduction, convection, radiation, evaporation, phase change, metabolic heat generation (heat generated by the body through the digestion of food, work and exercise), and perfusion (exchange of thermal energy between flowing blood and the surrounding tissue).

A simple yet fairly accurate bioheat transfer equation or model was proposed by Harry Pennes in 1948 and published in Volume 1 of the *Journal of Applied Physiology*. For the development of his model, Pennes measured temperature distributions as a function of radial position in the forearms of

nine human subjects. His data showed a temperature differential of 3 to 4°C between the skin and the interior of the arm. Pennes attributed this temperature difference to the effects of metabolic heat generation and perfusion in the arm. Based on his experimental results, Pennes proposed a model, now known as Pennes' bioheat transfer equation, to describe the effects of metabolism and blood perfusion on the energy balance within living tissue. Pennes' model was considered a major introductory effort in quantifying the heat transfer contribution of perfusion in tissue. His model is a modified version of the heat conduction equation introduced in Chapter 2 which accounts for the effects of metabolic heat generation and perfusion.

During the past decade, Pennes' bioheat transfer model has been widely used but also criticized for various reasons. To gain a better understanding of one of the most influential articles ever published in the *Journal of Applied Physiology*, Pennes' 1948 paper was republished for the 50th anniversary of the journal and was revisited in great depth by Wissler. Wissler reevaluated Pennes' work by revisiting his original experimental data and analysis. Wissler in his concluding remarks states that "much of the criticism directed toward Pennes' model is not justified and those who base their theoretical model calculations on the Pennes' model can be somewhat more confident that their starting equations are valid."

In this section a simplified version of the bioheat transfer equation for the case of steady-state, constant properties, one-dimensional heat transfer in rectangular coordinates is introduced. Following Pennes' model, modifying Eq. 2-15 to account for the effects of metabolic heat generation and perfusion heat sources results in

$$\frac{d^2T}{dx^2} + \frac{\dot{e}_m + \dot{e}_p}{k} = 0 \quad (3-85)$$

where  $\dot{e}_m$  and  $\dot{e}_p$  are the *metabolic* and *perfusion* heat source terms ( $\text{W/m}^3$ ).

A simple expression for the perfusion term was proposed by Pennes. Pennes suggested that the rate of heat transfer from blood to tissue per unit volume of tissue ( $\dot{e}_p$ ) is proportional to the perfusion rate  $\dot{p}$  (volumetric blood flow rate per unit volume of tissue or  $1/\text{s}$ ) and the difference between the blood temperature entering small capillaries (on the order of  $8 \mu\text{m}$ ) at an arterial inlet temperature of  $T_a$  and a perfusate of blood (consisting of mostly water and ions) exiting through the capillary wall at the local tissue temperature of  $T$ . It is important to note that blood can only leave the capillary through the venous end, but some perfusate of blood leaves through the wall. The expression proposed by Pennes for the exchange of thermal energy between flowing blood and the surrounding tissue (perfusion) is as follows

$$\dot{e}_p = \dot{p} \rho_b c_b (T_a - T) \quad (\text{W/m}^3) \quad (3-86)$$

where  $\rho_b$  ( $\text{kg/m}^3$ ) is the density of blood and  $c_b$  ( $\text{J/kg}\cdot\text{K}$ ) is the specific heat of blood.

Substituting the Pennes' perfusion heat source term expression, Eq. 3-86, into Eq. 3-85, results in

$$\frac{d^2T}{dx^2} + \frac{\dot{e}_m + \dot{p} \rho_b c_b (T_a - T)}{k} = 0 \quad (3-87)$$

Following the procedure that lead to Eq. 3–56 for extended surfaces and assuming constant  $\dot{e}_m, \dot{p}, \rho_b, c_b$  and  $T_a$ , the differential Eq. 3–87 reduces to

$$\frac{d^2\theta}{dx^2} - B^2\theta = 0 \quad (3-88)$$

where  $B^2 = \dot{p}\rho_b c_b/k$  has units of  $(1/m)$  and  $\theta = T - T_a - \dot{e}_m/\dot{p} \rho_b c_b$  is the *temperature excess*. Equation 3-88 is in form identical to Eq. 3–56 and the solutions presented in the text for the different boundary conditions could be used.

One of the applications of Eq. 3-88 is in a process called *thermoregulation*. Thermoregulation is the ability of an organism to regulate its body temperature within certain boundaries, even when the surrounding temperature is very different. Thermoregulation in the human body is achieved by keeping a tight balance between heat gain and heat loss. Humans' temperature regulation system is similar to the operation of a home furnace. The human body regulates heat generation and preservation to maintain the internal body temperature or core temperature. Normal core temperature at rest varies between  $36.5$  and  $37.5^\circ\text{C}$  ( $97.7$  to  $99.5^\circ\text{F}$ ). However, the temperature at the extremities is not regulated as tightly as the core temperature, and can vary significantly from the core temperature (imagine having a snowball fight without wearing gloves) and under normal external operating temperatures is in the range of  $33$ – $34^\circ\text{C}$ . A more realistic approach to the study of heat transfer within the human body is to solve the bioheat transfer equation in cylindrical coordinates as shown in the following equations.

The steady-state bioheat transfer differential equation in cylindrical coordinates with constant properties is

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{dT}{dr} \right) + \frac{\dot{e}_m + \dot{e}_p}{k} = 0 \quad (3-89)$$

Following the same procedure that lead to the development of Eq. 3–88, the bioheat transfer equation in cylindrical coordinates in terms of excess temperature  $\theta$  is

$$\frac{1}{r} \frac{d}{dr} \left( r \frac{d\theta}{dr} \right) - B^2\theta = 0 \quad (3-90)$$

Equation 3–90 is a *modified Bessel equation* of order zero, and its general solution is of the form

$$\theta(r) = C_1 I_0(Br) + C_2 K_0(Br) \quad (3-91)$$

where  $I_0$  and  $K_0$  are modified, zero-order Bessel functions of the first and second kinds, respectively. The values of  $I_0$  and  $K_0$  are given in Table 3–4.

One of the applications of Eq. 3–90 would be, for example, in the analysis of the steady-state heat transfer from a human forearm subjected to certain environmental conditions. One of the end-of-chapter problems will be on this subject. The following example demonstrates the use of Eq. 3–88 in calculating heat transfer between a human body and its surroundings.

**EXAMPLE 3–14 Application of Bioheat Transfer Equation**

We are interested in heat transfer analysis from a human body subjected to certain environmental conditions. For this purpose consider a region of muscle with a skin/fat layer over it under steady state conditions as shown in Fig. 3–51. For simplicity approximate this region as a one-dimensional plane wall with surface area  $A$ . The muscle thickness is  $L_m$  covered by a layer of skin/fat with a thickness  $L_{sf}$ . The metabolic heat generation rate ( $\dot{e}_m$ ) and perfusion rate ( $\dot{p}$ ) are both constant throughout the muscle. The blood density and specific heat are  $\rho_b$  and  $c_b$ , respectively. The core body temperate ( $T_c$ ) and the arterial blood temperature ( $T_a$ ) are both assumed to be the same and constant. The muscle and the skin/fat layer thermal conductivities are  $k_m$  and  $k_{sf}$ , respectively. The skin has an emissivity of  $\varepsilon$  and the body is subjected to an air environment with a temperature of  $T_\infty$ , a convection heat transfer coefficient of  $h_{\text{conv}}$ , and a radiation heat transfer coefficient of  $h_{\text{rad}}$ . Assuming blood properties and thermal conductivities are all constant, (a) develop an expression for the interface temperature ( $T_i$ ) between the muscle and the outer skin/fat layer, and (b) determine the temperature  $T_i$  and the rate of heat loss from the body ( $\dot{Q}_b$ ), and the skin temperature ( $T_s$ ) for the following conditions:

$$A = 1.8 \text{ m}^2, L_m = 0.03 \text{ m}, L_{sf} = 0.003 \text{ m}, \dot{e}_m = 700 \text{ W/m}^3, \dot{p} = 0.0005 \text{ 1/s}, T_c = T_a = 37^\circ\text{C}, T_\infty = T_{\text{surr}} = 24^\circ\text{C}, \varepsilon = 0.95, \rho_b = 1000 \text{ kg/m}^3, c_b = 3600 \text{ J/kg}\cdot\text{K}, k_m = 0.5 \text{ W/m}\cdot\text{K}, k_{sf} = 0.3 \text{ W/m}\cdot\text{K}, h_{\text{conv}} = 2 \text{ W/m}^2\cdot\text{K}, h_{\text{rad}} = 5.9 \text{ W/m}^2\cdot\text{K}$$

**SOLUTION** A region of muscle with a skin/fat layer over it for a human body is subjected to certain environmental conditions. An expression for the interface temperature, the value of the interface temperature, the rate of heat loss from the body, and the skin temperature for a set of conditions are to be determined.

**Assumptions** 1 Muscle and skin/fat layer considered as a 1-D plain wall. 2 Steady state conditions. 3 Blood properties, thermal conductivities, arterial temperature, core body temperature, metabolic heat generation rate, and perfusion rate are all constant. 4 Radiation exchange between the skin surface and the surroundings is between a small surface and a large enclosure at the air temperature. 5 Solar radiation is negligible.

**Properties** Muscle thermal conductivity  $k_m = 0.5 \text{ W/m}\cdot\text{K}$ , skin/fat layer thermal conductivity  $k_{sf} = 0.3 \text{ W/m}\cdot\text{K}$ , blood density  $\rho_b = 1000 \text{ kg/m}^3$  and blood specific heat  $c_b = 3600 \text{ J/kg}\cdot\text{K}$ .

**Analysis** (a) Solve the bioheat transfer differential equation, Eq. 3–88, along with the appropriate boundary conditions to develop an expression for the interface temperature ( $T_i$ ) between the muscle and the outer skin/fat layer. The bioheat differential equation is

$$\frac{d^2\theta}{dx^2} - B^2\theta = 0$$

**FIGURE 3–51**

Schematic for Example 3–14.

where  $B^2 = \dot{p}\rho_b c_b / k$  has units of  $(1/m)$  and  $\theta = T - T_a - \dot{e}_m/\dot{p}\rho_b c_b$ . The boundary conditions for the problem in terms of temperature excess  $\theta$  are:

$$\theta(0) = T_c - T_a - \dot{e}_m/\dot{p}\rho_b c_b = \theta_c \quad \text{and} \quad \theta(L_m) = T_i - T_a - \dot{e}_m/\dot{p}\rho_b c_b = \theta_i$$

The solution to Eq. 3-88 with the two specified temperature boundary conditions  $\theta_c$  and  $\theta_i$ , is given by Eq. 3-67 developed for fins (case 3 – specified temperature). For our case Eq. 3-67 becomes

$$\frac{\theta}{\theta_c} = \frac{(\theta_i/\theta_c)\sinh Bx + \sinh BL_m - x}{\sinh BL_m} \quad (3-92)$$

Note that  $T_i$  that appears in  $\theta_i$  in Eq. 3-92 is unknown. In order to find  $T_i$ , use Eq. 3-92 to calculate the rate at which heat leaves the muscle and enters the skin/fat layer at  $x = L_m$  and equate it with the rate at which heat is transferred through the skin/fat layer and into the environment.

Using the Fourier's law of heat conduction, the rate of heat transfer that leaves the muscle at  $x = L_m$  and enters the skin/fat layer is

$$\dot{Q}_{\text{specified temp.}} = -k_m A \frac{dT}{dx} \Big|_{x=L_m} = -k_m A \frac{d\theta}{dx} \Big|_{x=L_m} = -k_m AB \theta_c \frac{(\theta_i/\theta_c)\cosh BL_m - 1}{\sinh BL_m}$$

The rate at which heat is transferred through the skin/fat layer and into the environment is obtained by using the thermal resistance network concept (see section 3-1). In this case the thermal resistance is a combined series-parallel arrangement. Heat is transferred through the skin/fat layer by conduction in series and is in parallel with heat transfer by convection and radiation. The total rate of heat transfer through the skin/fat layer and into the environment (the rate of heat loss from the body) is

$$\dot{Q}_b = \frac{T_i - T_\infty}{R_{\text{total}}}$$

where the total resistance is  $R_{\text{total}} = R_{sf} + R_{\text{conv-rad}} = R_{sf} + \frac{R_{\text{conv}} R_{\text{rad}}}{R_{\text{conv}} + R_{\text{rad}}}$

and the individual resistances are  $R_{sf} = \frac{L_{sf}}{k_{sf}A}$ ,  $R_{\text{conv}} = \frac{1}{h_{\text{conv}}A}$  and  $R_{\text{rad}} = \frac{1}{h_{\text{rad}}A}$

Equating the rate of heat transfer that leaves the muscle at  $x = L_m$  and enters the skin/fat layer with the rate at which heat is transferred through the skin/fat layer and into the environment yields

$$-k_m AB \theta_c \frac{(\theta_i/\theta_c)\cosh BL_m - 1}{\sinh BL_m} = \frac{T_i - T_\infty}{R_{\text{total}}}$$

The above equation can be solved for  $T_i$ , the final expression is

$$T_i = \frac{T_\infty \sinh BL_m + k_m A B R_{\text{total}} \left[ \theta_c + \left( T_a + \frac{\dot{e}_m}{\dot{p}\rho_b c_b} \right) \cosh BL_m \right]}{\sinh BL_m + k_m A B R_{\text{total}} \cosh BL_m}$$

(b) Using the data given in the problem statement and the expression for the interface temperature ( $T_i$ ) between the muscle and the outer skin/fat layer, the interface temperature between the muscle and the outer skin/fat layer is

$$T_i = 34.8^\circ\text{C}$$

Using the calculated value of  $T_i$  and the equation for the total rate of heat transfer through the skin/fat layer and into the environment, the heat loss from the body is

$$\dot{Q}_b = 142 \text{ W}$$

The skin temperature ( $T_s$ ) can be calculated by applying the Fourier's law of heat conduction to the skin/fat layer

$$\dot{Q}_b = k_{sf}A \frac{T_i - T_s}{L_{sf}}$$

Solving the above equation for the  $T_s$

$$T_s = T_i - \frac{\dot{Q}_b L_{sf}}{k_{sf} A} \approx 34^\circ\text{C}$$

**Discussion** The skin temperature of  $34^\circ\text{C}$  is comfortable. However, if the environmental conditions change, our bodies will adjust to it. For example, if the air and the surroundings temperatures were lowered considerably, we will shiver. Shivering can increase the metabolic heat generation rate by up to six times the resting metabolic rate. If the air and the surroundings temperatures were increased considerably, we will sweat. Sweating will cause an increase in the perfusion rate near the skin surface which causes an increase in the heat loss to the surroundings via evaporation.

### 3-8 • HEAT TRANSFER IN COMMON CONFIGURATIONS

So far, we have considered heat transfer in *simple* geometries such as large plane walls, long cylinders, and spheres. This is because heat transfer in such geometries can be approximated as *one-dimensional*, and simple analytical solutions can be obtained easily. But many problems encountered in practice are two- or three-dimensional and involve rather complicated geometries for which no simple solutions are available.

An important class of heat transfer problems for which simple solutions are obtained encompasses those involving two surfaces maintained at *constant* temperatures  $T_1$  and  $T_2$ . The steady rate of heat transfer between these two surfaces is expressed as

$$Q = Sk(T_1 - T_2) \quad (3-93)$$

where  $S$  is the **conduction shape factor**, which has the dimension of *length*, and  $k$  is the thermal conductivity of the medium between the surfaces. The conduction shape factor depends on the *geometry* of the system only.

Conduction shape factors have been determined for a number of configurations encountered in practice and are given in Table 3-7 for some common cases. More comprehensive tables are available in the literature. Once the value of the shape factor is known for a specific geometry, the total steady heat transfer rate can be determined from the equation above using the specified two constant temperatures of the two surfaces and the thermal conductivity of the medium between them. Note that conduction shape factors are applicable only when heat transfer between the two surfaces is by *conduction*. Therefore, they cannot be used when the medium between the surfaces is a liquid or gas, which involves natural or forced convection currents.

A comparison of Eqs. 3-4 and 3-93 reveals that the conduction shape factor  $S$  is related to the thermal resistance  $R$  by  $R = 1/kS$  or  $S = 1/kR$ . Thus, these two quantities are the inverse of each other when the thermal conductivity of the medium is unity. The use of the conduction shape factors is illustrated with Examples 3-15 and 3-16.

**TABLE 3-7**

Conduction shape factors  $S$  for several configurations for use in  $\dot{Q} = kS(T_1 - T_2)$  to determine the steady rate of heat transfer through a medium of thermal conductivity  $k$  between the surfaces at temperatures  $T_1$  and  $T_2$

**EXAMPLE 3–15 Heat Loss from Buried Steam Pipes**

A 30-m-long, 10-cm-diameter hot-water pipe of a district heating system is buried in the soil 50 cm below the ground surface, as shown in Fig. 3–52. The outer surface temperature of the pipe is 80°C. Taking the surface temperature of the earth to be 10°C and the thermal conductivity of the soil at that location to be 0.9 W/m·K, determine the rate of heat loss from the pipe.

**SOLUTION** The hot-water pipe of a district heating system is buried in the soil. The rate of heat loss from the pipe is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer is two-dimensional (no change in the axial direction). 3 Thermal conductivity of the soil is constant.

**Properties** The thermal conductivity of the soil is given to be  $k = 0.9 \text{ W/m}\cdot\text{K}$ .

**Analysis** The shape factor for this configuration is given in Table 3–7 to be

$$S = \frac{2\pi L}{\ln(4z/D)}$$

since  $z > 1.5D$ , where  $z$  is the distance of the pipe from the ground surface, and  $D$  is the diameter of the pipe. Substituting,

$$S = \frac{2\pi \times (30 \text{ m})}{\ln(4 \times 0.5/0.1)} = 62.9 \text{ m}$$

Then the steady rate of heat transfer from the pipe becomes

$$\dot{Q} = Sk(T_1 - T_2) = (62.9 \text{ m})(0.9 \text{ W/m}\cdot\text{K})(80 - 10)^\circ\text{C} = \mathbf{3963 \text{ W}}$$

**Discussion** Note that this heat is conducted from the pipe surface to the surface of the earth through the soil and then transferred to the atmosphere by convection and radiation.

**EXAMPLE 3–16 Heat Transfer between Hot- and Cold-Water Pipes**

A 5-m-long section of hot- and cold-water pipes run parallel to each other in a thick concrete layer, as shown in Fig. 3–53. The diameters of both pipes are 5 cm, and the distance between the centerline of the pipes is 30 cm. The surface temperatures of the hot and cold pipes are 70°C and 15°C, respectively. Taking the thermal conductivity of the concrete to be  $k = 0.75 \text{ W/m}\cdot\text{K}$ , determine the rate of heat transfer between the pipes.

**SOLUTION** Hot- and cold-water pipes run parallel to each other in a thick concrete layer. The rate of heat transfer between the pipes is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer is two-dimensional (no change in the axial direction). 3 Thermal conductivity of the concrete is constant.

**Properties** The thermal conductivity of concrete is given to be  $k = 0.75 \text{ W/m}\cdot\text{K}$ .

**FIGURE 3–52**

Schematic for Example 3–15.

**FIGURE 3–53**

Schematic for Example 3–16.

**Analysis** The shape factor for this configuration is given in Table 3–7 to be

$$S = \frac{2\pi L}{\cosh^{-1}\left(\frac{4z^2 - D_1^2 - D_2^2}{2D_1D_2}\right)}$$

where  $z$  is the distance between the centerlines of the pipes and  $L$  is their length. Substituting,

$$S = \frac{2\pi \times (5 \text{ m})}{\cosh^{-1}\left(\frac{4 \times 0.3^2 - 0.05^2 - 0.05^2}{2 \times 0.05 \times 0.05}\right)} = 6.34 \text{ m}$$

Then the steady rate of heat transfer between the pipes becomes

$$\dot{Q} = Sk(T_1 - T_2) = (6.34 \text{ m})(0.75 \text{ W/m}\cdot\text{K})(70 - 15^\circ)\text{C} = 262 \text{ W}$$

**Discussion** We can reduce this heat loss by placing the hot- and cold-water pipes farther away from each other.

It is well known that insulation reduces heat transfer and saves energy and money. Decisions on the right amount of insulation are based on a heat transfer analysis, followed by an economic analysis to determine the “monetary value” of energy loss. This is illustrated with Example 3–17.

### EXAMPLE 3–17 Cost of Heat Loss through Walls in Winter

Consider an electrically heated house whose walls are 9 ft high and have an  $R$ -value of insulation of 13 (i.e., a thickness-to-thermal conductivity ratio of  $L/k = 13 \text{ h}\cdot\text{ft}^2\cdot^\circ\text{F/Btu}$ ). Two of the walls of the house are 40 ft long and the others are 30 ft long. The house is maintained at  $75^\circ\text{F}$  at all times, while the temperature of the outdoors varies. Determine the amount of heat lost through the walls of the house on a certain day during which the average temperature of the outdoors is  $45^\circ\text{F}$ . Also, determine the cost of this heat loss to the home owner if the unit cost of electricity is  $\$0.075/\text{kWh}$ . For combined convection and radiation heat transfer coefficients, use the ASHRAE (American Society of Heating, Refrigeration, and Air Conditioning Engineers) recommended values of  $h_i = 1.46 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$  for the inner surface of the walls and  $h_o = 6.0 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$  for the outer surface of the walls under 15 mph wind conditions in winter.

**SOLUTION** An electrically heated house with R-13 insulation is considered. The amount of heat lost through the walls and its cost are to be determined.

**Assumptions** 1 The indoor and outdoor air temperatures have remained at the given values for the entire day so that heat transfer through the walls is steady. 2 Heat transfer through the walls is one-dimensional since any significant temperature gradients in this case exist in the direction from the indoors to the outdoors. 3 The radiation effects are accounted for in the heat transfer coefficients.

**Analysis** This problem involves conduction through the wall and convection at its surfaces and can best be handled by making use of the thermal resistance concept and drawing the thermal resistance network, as shown in Fig. 3–54. The heat transfer area of the walls is

$$A = \text{Circumference} \times \text{Height} = (2 \times 30 \text{ ft} + 2 \times 40 \text{ ft})(9 \text{ ft}) = 1260 \text{ ft}^2$$

Then the individual resistances are evaluated from their definitions to be

$$R_i = R_{\text{conv}, i} = \frac{1}{h_i A} = \frac{1}{(1.46 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F})(1260 \text{ ft}^2)} = 0.00054 \text{ h}\cdot\text{F/Btu}$$

$$R_{\text{wall}} = \frac{L}{kA} = \frac{R \text{ value}}{A} = \frac{13 \text{ h}\cdot\text{ft}^2\cdot{}^\circ\text{F/Btu}}{1260 \text{ ft}^2} = 0.01032 \text{ h}\cdot\text{F/Btu}$$

$$R_o = R_{\text{conv}, o} = \frac{1}{h_o A} = \frac{1}{(6.0 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F})(1260 \text{ ft}^2)} = 0.00013 \text{ h}\cdot\text{F/Btu}$$

Noting that all three resistances are in series, the total resistance is

$$R_{\text{total}} = R_i + R_{\text{wall}} + R_o = 0.00054 + 0.01032 + 0.00013 = 0.01099 \text{ h}\cdot\text{F/Btu}$$

Then the steady rate of heat transfer through the walls of the house becomes

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}} = \frac{(75 - 45)^\circ\text{F}}{0.01099 \text{ h}\cdot\text{F/Btu}} = 2730 \text{ Btu/h}$$

Finally, the total amount of heat lost through the walls during a 24-h period and its cost to the home owner are

$$Q = \dot{Q} \Delta t = (2730 \text{ Btu/h})(24\text{-h/day}) = \mathbf{65,514 \text{ Btu/day} = 19.2 \text{ kWh/day}}$$

since 1 kWh = 3412 Btu, and

$$\begin{aligned} \text{Heating cost} &= (\text{Energy lost})(\text{Cost of energy}) = (19.2 \text{ kWh/day})(\$0.075/\text{kWh}) \\ &= \$1.44/\text{day} \end{aligned}$$

**Discussion** The heat losses through the walls of the house that day cost the home owner \$1.44 worth of electricity. Most of this loss can be saved by insulation.

**FIGURE 3–54**

Schematic for Example 3–17.

## TOPIC OF SPECIAL INTEREST\*

### Heat Transfer through Walls and Roofs

Under steady conditions, the rate of heat transfer through any section of a building wall or roof can be determined from

$$\dot{Q} = UA(T_i - T_o) = \frac{A(T_i - T_o)}{R} \quad (3-94)$$

where  $T_i$  and  $T_o$  are the indoor and outdoor air temperatures,  $A$  is the heat transfer area,  $U$  is the overall heat transfer coefficient (the  $U$ -factor), and

\* This section can be skipped without a loss of continuity.

$R = 1/U$  is the overall unit thermal resistance (the  $R$ -value). Walls and roofs of buildings consist of various layers of materials, and the structure and operating conditions of the walls and the roofs may differ significantly from one building to another. Therefore, it is not practical to list the  $R$ -values (or  $U$ -factors) of different kinds of walls or roofs under different conditions. Instead, the overall  $R$ -value is determined from the thermal resistances of the individual components using the thermal resistance network. The overall thermal resistance of a structure can be determined most accurately in a lab by actually assembling the unit and testing it as a whole, but this approach is usually very time consuming and expensive. The analytical approach described here is fast and straightforward, and the results are usually in good agreement with the experimental values.

The unit thermal resistance of a plane layer of thickness  $L$  and thermal conductivity  $k$  can be determined from  $R = L/k$ . The thermal conductivity and other properties of common building materials are given in the appendix. The unit thermal resistances of various components used in building structures are listed in Table 3–8 for convenience.

Heat transfer through a wall or roof section is also affected by the convection and radiation heat transfer coefficients at the exposed surfaces. The effects of convection and radiation on the inner and outer surfaces of walls and roofs are usually combined into the *combined convection and radiation heat transfer coefficients* (also called *surface conductances*)  $h_i$  and  $h_o$ ,

respectively, whose values are given in Table 3–9 for ordinary surfaces ( $\varepsilon = 0.9$ ) and reflective surfaces ( $\varepsilon = 0.2$  or  $0.05$ ). Note that surfaces having a low emittance also have a low surface conductance due to the reduction in radiation heat transfer. The values in the table are based on a surface temperature of  $21^\circ\text{C}$  ( $72^\circ\text{F}$ ) and a surface–air temperature difference of  $5.5^\circ\text{C}$  ( $10^\circ\text{F}$ ). Also, the equivalent surface temperature of the environment is assumed to be equal to the ambient air temperature. Despite the convenience it offers, this assumption is not quite accurate because of the additional radiation heat loss from the surface to the clear sky. The effect of sky radiation can be accounted for approximately by taking the outside temperature to be the average of the outdoor air and sky temperatures.

The inner surface heat transfer coefficient  $h_i$  remains fairly constant throughout the year, but the value of  $h_o$  varies considerably because of its dependence on the orientation and wind speed, which can vary from less than  $1 \text{ km/h}$  in calm weather to over  $40 \text{ km/h}$  during storms. The commonly used values of  $h_i$  and  $h_o$  for peak load calculations are

$$h_i = 8.29 \text{ W/m}^2\cdot\text{K} = 1.46 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F} \quad (\text{winter and summer})$$

$$h_o = \begin{cases} 34.0 \text{ W/m}^2\cdot\text{K} = 6.0 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F} & (\text{winter}) \\ 22.7 \text{ W/m}^2\cdot\text{K} = 4.0 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F} & (\text{summer}) \end{cases}$$

which correspond to design wind conditions of  $24 \text{ km/h}$  ( $15 \text{ mph}$ ) for winter and  $12 \text{ km/h}$  ( $7.5 \text{ mph}$ ) for summer. The corresponding surface thermal resistances ( $R$ -values) are determined from  $R_i = 1/h_i$  and  $R_o = 1/h_o$ . The surface conductance values under still air conditions can be used for interior surfaces as well as exterior surfaces in calm weather.

Building components often involve *trapped air spaces* between various layers. Thermal resistances of such air spaces depend on the thickness of the layer, the temperature difference across the layer, the mean air temperature, the emissivity of each surface, the orientation of the air layer, and the direction of heat transfer. The emissivities of surfaces commonly encountered in buildings are given in Table 3–10. The **effective emissivity** of a plane-parallel air space is given by

$$\frac{1}{\varepsilon_{\text{effective}}} = \frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1 \quad (3-95)$$

where  $\varepsilon_1$  and  $\varepsilon_2$  are the emissivities of the surfaces of the air space. Table 3–10 also lists the effective emissivities of air spaces for the cases where (1) the emissivity of one surface of the air space is  $\varepsilon$  while the emissivity of the other surface is  $0.9$  (a building material) and (2) the emissivity of both surfaces is  $\varepsilon$ . Note that the effective emissivity of an air space between building materials is  $0.82/0.03 = 27$  times that of an air space between surfaces covered with aluminum foil. For specified surface temperatures, radiation heat transfer through an air space is proportional to effective emissivity, and thus the rate of radiation heat transfer in the ordinary surface case is 27 times that of the reflective surface case.

Table 3–11 lists the thermal resistances of 20-mm-, 40-mm-, and 90-mm-(0.75-in, 1.5-in, and 3.5-in) thick air spaces under various conditions. The

\*Surface emissivity of aluminum foil increases to 0.30 with barely visible condensation, and to 0.70 with clearly visible condensation.

**FIGURE 3-55**

Ventilation paths for a naturally ventilated attic and the appropriate size of the flow areas around the radiant barrier for proper air circulation.

From DOE/CE-0335P, U.S. Dept. of Energy.

thermal resistance values in the table are applicable to air spaces of uniform thickness bounded by plane, smooth, parallel surfaces with no air leakage. Thermal resistances for other temperatures, emissivities, and air spaces can be obtained by interpolation and moderate extrapolation. Note that the presence of a low-emissivity surface reduces radiation heat transfer across an air space and thus significantly increases the thermal resistance. The thermal effectiveness of a low-emissivity surface will decline, however, if the condition of the surface changes as a result of some effects such as condensation, surface oxidation, and dust accumulation.

The  $R$ -value of a wall or roof structure that involves layers of uniform thickness is determined easily by simply adding up the unit thermal resistances of the layers that are in series. But when a structure involves components such as wood studs and metal connectors, then the thermal resistance network involves parallel connections and possible two-dimensional effects. The overall  $R$ -value in this case can be determined by assuming (1) parallel heat flow paths through areas of different construction or (2) isothermal planes normal to the direction of heat transfer. The first approach usually overpredicts the overall thermal resistance, whereas the second approach usually underpredicts it. The parallel heat flow path approach is more suitable for wood frame walls and roofs, whereas the isothermal planes approach is more suitable for masonry or metal frame walls.

The thermal contact resistance between different components of building structures ranges between 0.01 and 0.1  $\text{m}^2 \cdot ^\circ\text{C}/\text{W}$ , which is negligible in most cases. However, it may be significant for metal building components such as steel framing members.

The construction of wood frame flat ceilings typically involve 2-in  $\times$  6-in joists on 400-mm (16-in) or 600-mm (24-in) centers. The fraction of framing is usually taken to be 0.10 for joists on 400-mm centers and 0.07 for joists on 600-mm centers.

Most buildings have a combination of a ceiling and a roof with an attic space in between, and the determination of the  $R$ -value of the roof–attic–ceiling combination depends on whether the attic is vented or not. For adequately ventilated attics, the attic air temperature is practically the same as the outdoor air temperature, and thus heat transfer through the roof is governed by the  $R$ -value of the ceiling only. However, heat is also transferred between the roof and the ceiling by radiation, and it needs to be considered (Fig. 3-55). The major function of the roof in this case is to serve as a radiation shield by blocking off solar radiation. Effectively ventilating the attic in summer should not lead one to believe that heat gain to the building through the attic is greatly reduced. This is because most of the heat transfer through the attic is by radiation.

Radiation heat transfer between the ceiling and the roof can be minimized by covering at least one side of the attic (the roof or the ceiling side) by a reflective material, called *radiant barrier*, such as aluminum foil or aluminum-coated paper. Tests on houses with  $R$ -19 attic floor insulation have shown that radiant barriers can reduce summer ceiling heat gains by 16 to 42 percent compared to an attic with the same insulation level and no radiant barrier. Considering that the ceiling heat gain represents

**TABLE 3-11**

Unit thermal resistances (*R*-values) of well-sealed plane air spaces (from ASHRAE *Handbook of Fundamentals*, Chap. 22, Table 2)  
(a) SI units (in  $\text{m}^2 \cdot ^\circ\text{C}/\text{W}$ )

**FIGURE 3-55**

Three possible locations for an attic radiant barrier.

From DOE/CE-0335P, U.S. Dept. of Energy.

about 15 to 25 percent of the total cooling load of a house, radiant barriers will reduce the air conditioning costs by 2 to 10 percent. Radiant barriers also reduce the heat loss in winter through the ceiling, but tests have shown that the percentage reduction in heat losses is less. As a result, the percentage reduction in heating costs will be less than the reduction in the air-conditioning costs. Also, the values given are for new and undusted radiant barrier installations, and percentages will be lower for aged or dusty radiant barriers.

Some possible locations for attic radiant barriers are given in Figure 3-56. In whole house tests on houses with  $R$ -19 attic floor insulation, radiant barriers have reduced the ceiling heat gain by an average of 35 percent when the radiant barrier is installed on the attic floor, and by 24 percent when it is attached to the bottom of roof rafters. Test cell tests also demonstrated that the best location for radiant barriers is the attic floor, provided that the attic is not used as a storage area and is kept clean.

For unvented attics, any heat transfer must occur through (1) the ceiling, (2) the attic space, and (3) the roof (Fig. 3-57). Therefore, the overall  $R$ -value of the roof-ceiling combination with an unvented attic depends on the combined effects of the  $R$ -value of the ceiling and the  $R$ -value of the roof as well as the thermal resistance of the attic space. The attic space can be treated as an air layer in the analysis. But a more practical way of accounting for its effect is to consider surface resistances on the roof and ceiling surfaces facing each other. In this case, the  $R$ -values of the ceiling and the roof are first determined separately (by using convection resistances for the still-air case for the attic surfaces). Then it can be shown that the overall  $R$ -value of the ceiling-roof combination per unit area of the ceiling can be expressed as

$$R = R_{\text{ceiling}} + R_{\text{roof}} \left( \frac{A_{\text{ceiling}}}{A_{\text{roof}}} \right) \quad (3-96)$$

**FIGURE 3-57**

Thermal resistance network for a pitched roof-attic-ceiling combination for the case of an unvented attic.

where  $A_{\text{ceiling}}$  and  $A_{\text{roof}}$  are the ceiling and roof areas, respectively. The area ratio is equal to 1 for flat roofs and is less than 1 for pitched roofs. For a 45° pitched roof, the area ratio is  $A_{\text{ceiling}}/A_{\text{roof}} = 1/\sqrt{2} = 0.707$ . Note that the pitched roof has a greater area for heat transfer than the flat ceiling, and the area ratio accounts for the reduction in the unit  $R$ -value of the roof when expressed per unit area of the ceiling. Also, the direction of heat flow is up in winter (heat loss through the roof) and down in summer (heat gain through the roof).

The  $R$ -value of a structure determined by analysis assumes that the materials used and the quality of workmanship meet the standards. Poor workmanship and substandard materials used during construction may result in  $R$ -values that deviate from predicted values. Therefore, some engineers use a safety factor in their designs based on experience in critical applications.

### EXAMPLE 3–18 The $R$ -Value of a Wood Frame Wall

Determine the overall unit thermal resistance (the  $R$ -value) and the overall heat transfer coefficient (the  $U$ -factor) of a wood frame wall that is built around 38-mm × 90-mm (2 × 4 nominal) wood studs with a center-to-center distance of 400 mm. The 90-mm-wide cavity between the studs is filled with glass fiber insulation. The inside is finished with 13-mm gypsum wallboard and the outside with 13-mm wood fiberboard and 13-mm × 200-mm wood bevel lapped siding. The insulated cavity constitutes 75 percent of the heat transmission area while the studs, plates, and sills constitute 21 percent. The headers constitute 4 percent of the area, and they can be treated as studs.

Also, determine the rate of heat loss through the walls of a house whose perimeter is 50 m and wall height is 2.5 m in Las Vegas, Nevada, whose winter design temperature is  $-2^{\circ}\text{C}$ . Take the indoor design temperature to be  $22^{\circ}\text{C}$  and assume 20 percent of the wall area is occupied by glazing.

**SOLUTION** The  $R$ -value and the  $U$ -factor of a wood frame wall as well as the rate of heat loss through such a wall in Las Vegas are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer through the wall is one-dimensional. 3 Thermal properties of the wall and the heat transfer coefficients are constant.

**Properties** The  $R$ -values of different materials are given in Table 3–8.

**Analysis** The schematic of the wall as well as the different elements used in its construction are shown here. Heat transfer through the insulation and through the studs meets different resistances, and thus we need to analyze the thermal resistance for each path separately. Once the unit thermal resistances and the  $U$ -factors for the insulation and stud sections are available, the overall average thermal resistance for the entire wall can be determined from

$$R_{\text{overall}} = 1/U_{\text{overall}}$$

where

$$U_{\text{overall}} = (U \times f_{\text{area}})_{\text{insulation}} + (U \times f_{\text{area}})_{\text{stud}}$$

and the value of the area fraction  $f_{\text{area}}$  is 0.75 for the insulation section and 0.25 for the stud section since the headers that constitute a small part of the wall are to be treated as studs. Using the available  $R$ -values from Table 3–8 and calculating others, the total  $R$ -values for each section can be determined in a systematic manner in the table below.

Schematic

| 3. Wood fiberboard<br>sheeting, 13 mm | 0.23                                  | 0.23     |
| 4a. Glass fiber<br>insulation, 90 mm  | 2.45                                  | —        |
| 6 4b. Wood stud,<br>38 mm × 90 mm     | —                                     | 0.63     |
| 5. Gypsum wallboard,<br>13 mm         | 0.079                                 | 0.079    |
| 6. Inside surface, still air          | 0.12                                  | 0.12     |

|   |                                       |       |
|---|---------------------------------------|-------|
| Total unit thermal resistance of each section, $R$<br>(in m <sup>2</sup> ·°C/W)   | 3.05                                  | 1.23  |
| The $U$ -factor of each section, $U = 1/R$ , in W/m <sup>2</sup> ·K   | 0.328                                 | 0.813 |
| Area fraction of each section, $f_{\text{area}}$  | 0.75                                  | 0.25  |
| Overall $U$ -factor: $U = \sum f_{\text{area}, i} U_i = 0.75 \times 0.328 + 0.25 \times 0.813$<br>= 0.449 W/m <sup>2</sup> ·K |                                       |       |
| Overall unit thermal resistance:  | $R = 1/U = 2.23$ m <sup>2</sup> ·°C/W |       |

We conclude that the overall unit thermal resistance of the wall is 2.23 m<sup>2</sup>·°C/W, and this value accounts for the effects of the studs and headers. It corresponds to an  $R$ -value of  $2.23 \times 5.68 = 12.7$  (or nearly  $R$ -13) in English units. Note that if there were no wood studs and headers in the wall, the overall thermal resistance would be 3.05 m<sup>2</sup>·°C/W, which is 37 percent greater than 2.23 m<sup>2</sup>·°C/W. Therefore, the wood studs and headers in this case serve as thermal bridges in wood frame walls, and their effect must be considered in the thermal analysis of buildings.

The perimeter of the building is 50 m and the height of the walls is 2.5 m. Noting that glazing constitutes 20 percent of the walls, the total wall area is

$$A_{\text{wall}} = 0.80(\text{Perimeter})(\text{Height}) = 0.80(50 \text{ m})(2.5 \text{ m}) = 100 \text{ m}^2$$

Then the rate of heat loss through the walls under design conditions becomes

$$\begin{aligned}\dot{Q}_{\text{wall}} &= (UA)_{\text{wall}} (T_i - T_o) \\ &= (0.449 \text{ W/m}^2 \cdot \text{K})(100 \text{ m}^2)[22 - (-2)^\circ\text{C}] \\ &= 1078 \text{ W}\end{aligned}$$

**Discussion** Note that a 1-kW resistance heater in this house will make up almost all the heat lost through the walls, except through the doors and windows, when the outdoor air temperature drops to  $-2^\circ\text{C}$ .

**EXAMPLE 3–19** The *R*-Value of a Wall with Rigid Foam

The 13-mm-thick wood fiberboard sheathing of the wood stud wall discussed in the previous example is replaced by a 25-mm-thick rigid foam insulation. Determine the percent increase in the *R*-value of the wall as a result.

**SOLUTION** The overall *R*-value of the existing wall was determined in Example 3–18 to be  $2.23 \text{ m}^2 \cdot ^\circ\text{C/W}$ . Noting that the *R*-values of the fiberboard and the foam insulation are  $0.23 \text{ m}^2 \cdot ^\circ\text{C/W}$  and  $0.98 \text{ m}^2 \cdot ^\circ\text{C/W}$ , respectively, and the added and removed thermal resistances are in series, the overall *R*-value of the wall after modification becomes

$$\begin{aligned}R_{\text{new}} &= R_{\text{old}} - R_{\text{removed}} + R_{\text{added}} \\&= 2.23 - 0.23 + 0.98 \\&= 2.98 \text{ m}^2 \cdot ^\circ\text{C/W}\end{aligned}$$

This represents an increase of  $(2.98 - 2.23)/2.23 = 0.34$  or **34 percent** in the *R*-value of the wall. This example demonstrated how to evaluate the new *R*-value of a structure when some structural members are added or removed.

**EXAMPLE 3–20** The *R*-Value of a Masonry Wall

Determine the overall unit thermal resistance (the *R*-value) and the overall heat transfer coefficient (the *U*-factor) of a masonry cavity wall that is built around 6-in-thick concrete blocks made of lightweight aggregate with 3 cores filled with perlite ( $R = 4.2 \text{ h} \cdot \text{ft}^2 \cdot ^\circ\text{F/Btu}$ ). The outside is finished with 4-in face brick with  $\frac{1}{2}$ -in cement mortar between the bricks and concrete blocks. The inside finish consists of  $\frac{1}{2}$ -in gypsum wallboard separated from the concrete block by  $\frac{3}{4}$ -in-thick (1-in  $\times$  3-in nominal) vertical furring ( $R = 4.2 \text{ h} \cdot \text{ft}^2 \cdot ^\circ\text{F/Btu}$ ) whose center-to-center distance is 16 in. Both sides of the  $\frac{1}{2}$ -in-thick air space between the concrete block and the gypsum board are coated with reflective aluminum foil ( $\epsilon = 0.05$ ) so that the effective emissivity of the air space is 0.03. For a mean temperature of  $50^\circ\text{F}$  and a temperature difference of  $30^\circ\text{F}$ , the *R*-value of the air space is  $2.91 \text{ h} \cdot \text{ft}^2 \cdot ^\circ\text{F/Btu}$ . The reflective air space constitutes 80 percent of the heat transmission area, while the vertical furring constitutes 20 percent.

**SOLUTION** The *R*-value and the *U*-factor of a masonry cavity wall are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer through the wall is one-dimensional. 3 Thermal properties of the wall and the heat transfer coefficients are constant.

**Properties** The *R*-values of different materials are given in Table 3–8.

**Analysis** The schematic of the wall as well as the different elements used in its construction are shown below. Following the approach described here and using the available *R*-values from Table 3–8, the overall *R*-value of the wall is determined in the following table.

| Construction   | R-value,<br>h·ft <sup>2</sup> ·°F/Btu                                 |            |
|--|---|------------|
|  | Between Furring   | At Furring |
| 1. Outside surface,<br>15 mph wind   | 0.17  | 0.17       |
| 2. Face brick, 4 in  | 0.43  | 0.43       |
| 3. Cement mortar,<br>0.5 in  | 0.10  | 0.10       |
| 4. Concrete block,<br>6 in   | 4.20  | 4.20       |
| 5a. Reflective air<br>space, $\frac{3}{4}$ in  | 2.91  | —          |
| 5b. Nominal 1 × 3<br>vertical furring  | —   | 0.94       |
| 6. Gypsum wallboard,<br>0.5 in   | 0.45  | 0.45       |
| 7. Inside surface,<br>still air  | 0.68  | 0.68       |
| Total unit thermal resistance of each section, $R$   | 8.94  | 6.97       |
| The $U$ -factor of each section, $U = 1/R$ , in Btu/h·ft <sup>2</sup> ·°F  | 0.112   | 0.143      |
| Area fraction of each section, $f_{\text{area}}$   | 0.80  | 0.20       |
| Overall $U$ -factor: $U = \sum f_{\text{area}, i} U_i = 0.80 \times 0.112 + 0.20 \times 0.143$<br>= <b>0.118 Btu/h·ft<sup>2</sup>·°F</b>   |   |            |
| Overall unit thermal resistance:   | $R = 1/U = \mathbf{8.46 \text{ h}\cdot\text{ft}^2\cdot\text{°F/Btu}}$ |            |
| Therefore, the overall unit thermal resistance of the wall is 8.46 h·ft <sup>2</sup> ·°F/Btu and the overall $U$ -factor is 0.118 Btu/h·ft <sup>2</sup> ·°F. These values account for the effects of the vertical furring. |   |            |

**EXAMPLE 3-21** The R-Value of a Pitched Roof

Determine the overall unit thermal resistance (the  $R$ -value) and the overall heat transfer coefficient (the  $U$ -factor) of a 45° pitched roof built around nominal 2-in × 4-in wood studs with a center-to-center distance of 16 in. The 3.5-in-wide air space between the studs does not have any reflective surface and thus its effective emissivity is 0.84. For a mean temperature of 90°F and a temperature difference of 30°F, the  $R$ -value of the air space is 0.86 h·ft<sup>2</sup>·°F/Btu. The lower part of the roof is finished with  $\frac{1}{2}$ -in gypsum wallboard and the upper part with  $\frac{5}{8}$ -in plywood, building paper, and asphalt shingle roofing. The air space constitutes 75 percent of the heat transmission area, while the studs and headers constitute 25 percent.

**SOLUTION** The  $R$ -value and the  $U$ -factor of a 45° pitched roof are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Heat transfer through the roof is one-dimensional. 3 Thermal properties of the roof and the heat transfer coefficients are constant.

**Properties** The  $R$ -values of different materials are given in Table 3–8.

**Analysis** The schematic of the pitched roof as well as the different elements used in its construction are shown below. Following the approach described above and using the available  $R$ -values from Table 3–8, the overall  $R$ -value of the roof can be determined in the table here.

Schematic

| Overall $U$ -factor: $U = \sum f_{\text{area}, i} U_i = 0.75 \times 0.292 + 0.25 \times 0.163$<br>= <b>0.260 <math>\text{Btu}/\text{h}\cdot\text{ft}^2\cdot^\circ\text{F}</math></b> |  |             |
| Overall unit thermal resistance:   | $R = 1/U = \text{3.85 h}\cdot\text{ft}^2\cdot^\circ\text{F}/\text{Btu}$      |             |

Therefore, the overall unit thermal resistance of this pitched roof is  $3.85 \text{ h}\cdot\text{ft}^2\cdot^\circ\text{F}/\text{Btu}$  and the overall  $U$ -factor is  $0.260 \text{ Btu}/\text{h}\cdot\text{ft}^2\cdot^\circ\text{F}$ . Note that the wood studs offer much larger thermal resistance to heat flow than the air space between the studs.

## SUMMARY

One-dimensional heat transfer through a simple or composite body exposed to convection from both sides to mediums at temperatures  $T_{\infty 1}$  and  $T_{\infty 2}$  can be expressed as

$$\dot{Q} = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}}$$

where  $R_{\text{total}}$  is the total thermal resistance between the two mediums. For a plane wall exposed to convection on both sides, the total resistance is expressed as

$$R_{\text{total}} = R_{\text{conv}, 1} + R_{\text{wall}} + R_{\text{conv}, 2} = \frac{1}{h_1 A} + \frac{L}{kA} + \frac{1}{h_2 A}$$

This relation can be extended to plane walls that consist of two or more layers by adding an additional resistance for each

additional layer. The elementary thermal resistance relations can be expressed as follows:

$$\text{Conduction resistance (plane wall): } R_{\text{wall}} = \frac{L}{kA}$$

$$\text{Conduction resistance (cylinder): } R_{\text{cyl}} = \frac{\ln(r_2/r_1)}{2\pi L k}$$

$$\text{Conduction resistance (sphere): } R_{\text{sph}} = \frac{r_2 - r_1}{4\pi r_1 r_2 k}$$

$$\text{Convection resistance: } R_{\text{conv}} = \frac{1}{hA}$$

$$\text{Interface resistance: } R_{\text{interface}} = \frac{1}{h_c A} = \frac{R_c}{A}$$

$$\text{Radiation resistance: } R_{\text{rad}} = \frac{1}{h_{\text{rad}} A}$$

where  $h_c$  is the thermal contact conductance,  $R_c$  is the thermal contact resistance, and the radiation heat transfer coefficient is defined as

$$h_{\text{rad}} = \varepsilon\sigma(T_s^2 + T_{\text{surr}}^2)(T_s + T_{\text{surr}})$$

Once the rate of heat transfer is available, the *temperature drop* across any layer can be determined from

$$\Delta T = \dot{Q}R$$

The thermal resistance concept can also be used to solve steady heat transfer problems involving parallel layers or combined series-parallel arrangements.

Adding insulation to a cylindrical pipe or a spherical shell increases the rate of heat transfer if the outer radius of the insulation is less than the *critical radius of insulation*, defined as

$$r_{\text{cr, cylinder}} = \frac{k_{\text{ins}}}{h}$$

$$r_{\text{cr, sphere}} = \frac{2k_{\text{ins}}}{h}$$

The effectiveness of an insulation is often given in terms of its *R-value*, the thermal resistance of the material for a unit surface area, expressed as

$$R\text{-value} = \frac{L}{k} \quad (\text{flat insulation})$$

where  $L$  is the thickness and  $k$  is the thermal conductivity of the material.

Finned surfaces are commonly used in practice to enhance heat transfer. Fins enhance heat transfer from a surface by exposing a larger surface area to convection. The temperature distribution along the fin are given by

$$\text{Very long fin: } \frac{T(x) - T_{\infty}}{T_b - T_{\infty}} = e^{-x\sqrt{hp/kA_c}}$$

$$\text{Adiabatic fin tip: } \frac{T(x) - T_{\infty}}{T_b - T_{\infty}} = \frac{\cosh mx(L-x)}{\cosh mL}$$

*Specified temperature at fin tip:*

$$\frac{T(x) - T_{\infty}}{T_b - T_{\infty}} = \frac{[(T_L - T_{\infty})/(T_b - T_{\infty})]\sinh mx + \sinh m(L-x)}{\sinh mL}$$

*Convection from fin tip:*

$$\frac{T(x) - T_{\infty}}{T_b - T_{\infty}} = \frac{\cosh m(L-x) + (h/mk) \sinh m(L-x)}{\cosh mL + (h/mk) \sinh mL}$$

where  $m = \sqrt{hp/kA_c}$ ,  $p$  is the perimeter, and  $A_c$  is the cross-sectional area of the fin. The rates of heat transfer for these cases are given to be

*Very long fin:*

$$\dot{Q}_{\text{long fin}} = -kA_c \frac{dT}{dx} \Big|_{x=0} = \sqrt{hpkA_c} (T_b - T_{\infty})$$

*Adiabatic fin tip:*

$$\dot{Q}_{\text{adiabatic tip}} = -kA_c \frac{dT}{dx} \Big|_{x=0} = \sqrt{hpkA_c} (T_b - T_{\infty}) \tanh mL$$

*Specified temperature at fin tip:*

$$\dot{Q}_{\text{specified temp.}} = \sqrt{hpkA_c} (T_b - T_{\infty}) \frac{\cosh mL - [(T_L - T_{\infty})/(T_b - T_{\infty})]}{\sinh mL}$$

*Convection from the fin tip:*

$$\dot{Q}_{\text{convection}} = \sqrt{hpkA_c} (T_b - T_{\infty}) \frac{\sinh mL + (h/mk) \cosh mL}{\cosh mL + (h/mk) \sinh mL}$$

Fins exposed to convection at their tips can be treated as fins with adiabatic tips by using the corrected length  $L_c = L + A_c/p$  instead of the actual fin length.

The temperature of a fin drops along the fin, and thus the heat transfer from the fin is less because of the decreasing temperature difference toward the fin tip. To account for the effect of this decrease in temperature on heat transfer, we define *fin efficiency* as

$$\eta_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{fin, max}}} = \frac{\text{Actual heat transfer rate from the fin}}{\text{Ideal heat transfer rate from the fin if the entire fin were at base temperature}}$$

When the fin efficiency is available, the rate of heat transfer from a fin can be determined from

$$\dot{Q}_{\text{fin}} = \eta_{\text{fin}} \dot{Q}_{\text{fin, max}} = \eta_{\text{fin}} hA_{\text{fin}} (T_b - T_{\infty})$$

The performance of the fins is judged on the basis of the enhancement in heat transfer relative to the no-fin case and is expressed in terms of the *fin effectiveness*  $\varepsilon_{\text{fin}}$ , defined as

$$\varepsilon_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{no fin}}} = \frac{\dot{Q}_{\text{fin}}}{hA_b (T_b - T_{\infty})} = \frac{\text{Heat transfer rate from the fin of base area } A_b}{\text{Heat transfer rate from the surface of area } A_b}$$

Here,  $A_b$  is the cross-sectional area of the fin at the base and  $\dot{Q}_{\text{no fin}}$  represents the rate of heat transfer from this area if no fins are attached to the surface. The *overall effectiveness* for a finned surface is defined as the ratio of the total heat transfer from the finned surface to the heat transfer from the same surface if there were no fins,

$$\varepsilon_{\text{fin, overall}} = \frac{\dot{Q}_{\text{total, fin}}}{\dot{Q}_{\text{total, no fin}}} = \frac{h(A_{\text{unfin}} + \eta_{\text{fin}} A_{\text{fin}})(T_b - T_{\infty})}{hA_{\text{no fin}} (T_b - T_{\infty})}$$

Fin efficiency and fin effectiveness are related to each other by

$$\varepsilon_{\text{fin}} = \frac{A_{\text{fin}}}{A_b} \eta_{\text{fin}}$$

Certain multidimensional heat transfer problems involve two surfaces maintained at constant temperatures  $T_1$  and  $T_2$ . The steady rate of heat transfer between these two surfaces is expressed as

$$\dot{Q} = Sk(T_1 - T_2)$$

where  $S$  is the *conduction shape factor* that has the dimension of *length* and  $k$  is the thermal conductivity of the medium between the surfaces.

## PROBLEMS\*

**Steady Heat Conduction in Plane Walls**

**3–1C** Consider heat conduction through a wall of thickness  $L$  and area  $A$ . Under what conditions will the temperature distributions in the wall be a straight line?

**3–2C** Consider heat conduction through a plane wall. Does the energy content of the wall change during steady heat conduction? How about during transient conduction? Explain.

**3–3C** What does the thermal resistance of a medium represent?

**3–4C** Can we define the convection resistance for a unit surface area as the inverse of the convection heat transfer coefficient?

\*Problems designated by a "C" are concept questions, and students are encouraged to answer them all. Problems designated by an "E" are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature, and are intended to be solved with an equation solver such as EES. Problems with the icon are Prevention through Design problems.

**3–5C** Consider steady heat transfer through the wall of a room in winter. The convection heat transfer coefficient at the outer surface of the wall is three times that of the inner surface as a result of the winds. On which surface of the wall do you think the temperature will be closer to the surrounding air temperature? Explain.

**3–6C** How is the combined heat transfer coefficient defined? What convenience does it offer in heat transfer calculations?

**3–7C** Why are the convection and the radiation resistances at a surface in parallel instead of being in series?

**3–8C** Consider steady one-dimensional heat transfer through a plane wall exposed to convection from both sides to environments at known temperatures  $T_{\infty 1}$  and  $T_{\infty 2}$  with known heat transfer coefficients  $h_1$  and  $h_2$ . Once the rate of heat transfer  $\dot{Q}$  has been evaluated, explain how you would determine the temperature of each surface.

**3–9C** Someone comments that a microwave oven can be viewed as a conventional oven with zero convection resistance at the surface of the food. Is this an accurate statement?

**3–10C** Consider two cold canned drinks, one wrapped in a blanket and the other placed on a table in the same room. Which drink will warm up faster?

**3-11C** The bottom of a pan is made of a 4-mm-thick aluminum layer. In order to increase the rate of heat transfer through the bottom of the pan, someone proposes a design for the bottom that consists of a 3-mm-thick copper layer sandwiched between two 2-mm-thick aluminum layers. Will the new design conduct heat better? Explain. Assume perfect contact between the layers.

FIGURE P3-11C

**3-12C** Consider a surface of area  $A$  at which the convection and radiation heat transfer coefficients are  $h_{\text{conv}}$  and  $h_{\text{rad}}$ , respectively. Explain how you would determine (a) the single equivalent heat transfer coefficient, and (b) the equivalent thermal resistance. Assume the medium and the surrounding surfaces are at the same temperature.

**3-13C** How does the thermal resistance network associated with a single-layer plane wall differ from the one associated with a five-layer composite wall?

**3-14C** Consider steady one-dimensional heat transfer through a multilayer medium. If the rate of heat transfer  $\dot{Q}$  is known, explain how you would determine the temperature drop across each layer.

**3-15C** Consider a window glass consisting of two 4-mm-thick glass sheets pressed tightly against each other. Compare the heat transfer rate through this window with that of one consisting of a single 8-mm-thick glass sheet under identical conditions.

**3-16** Consider a 3-m-high, 6-m-wide, and 0.3-m-thick brick wall whose thermal conductivity is  $k = 0.8 \text{ W/m}\cdot\text{K}$ . On a certain day, the temperatures of the inner and the outer surfaces of the wall are measured to be  $14^\circ\text{C}$  and  $2^\circ\text{C}$ , respectively. Determine the rate of heat loss through the wall on that day.

**3-17** Consider a person standing in a room at  $20^\circ\text{C}$  with an exposed surface area of  $1.7 \text{ m}^2$ . The deep body temperature of the human body is  $37^\circ\text{C}$ , and the thermal conductivity of the human tissue near the skin is about  $0.3 \text{ W/m}\cdot\text{K}$ . The body

is losing heat at a rate of  $150 \text{ W}$  by natural convection and radiation to the surroundings. Taking the body temperature  $0.5 \text{ cm}$  beneath the skin to be  $37^\circ\text{C}$ , determine the skin temperature of the person. *Answer:  $35.5^\circ\text{C}$*

**3-18E** Consider an electrically heated brick house ( $k = 0.40 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) whose walls are  $9 \text{ ft}$  high and  $1 \text{ ft}$  thick. Two of the walls of the house are  $50 \text{ ft}$  long and the others are  $35 \text{ ft}$  long. The house is maintained at  $70^\circ\text{F}$  at all times while the temperature of the outdoors varies. On a certain day, the temperature of the inner surface of the walls is measured to be at  $55^\circ\text{F}$  while the average temperature of the outer surface is observed to remain at  $45^\circ\text{F}$  during the day for  $10 \text{ h}$  and at  $35^\circ\text{F}$  at night for  $14 \text{ h}$ . Determine the amount of heat lost from the house that day. Also determine the cost of that heat loss to the home owner for an electricity price of  $\$0.09/\text{kWh}$ .

FIGURE P3-18E

**3-19** A  $12\text{-cm} \times 18\text{-cm}$  circuit board houses on its surface 100 closely spaced logic chips, each dissipating  $0.06 \text{ W}$  in an environment at  $40^\circ\text{C}$ . The heat transfer from the back surface of the board is negligible. If the heat transfer coefficient on the surface of the board is  $10 \text{ W/m}^2\cdot\text{K}$ , determine (a) the heat flux on the surface of the circuit board, in  $\text{W/m}^2$ ; (b) the surface temperature of the chips; and (c) the thermal resistance between the surface of the circuit board and the cooling medium, in  $^\circ\text{C/W}$ .

**3-20** Water is boiling in a  $25\text{-cm-diameter}$  aluminum pan ( $k = 237 \text{ W/m}\cdot\text{K}$ ) at  $95^\circ\text{C}$ . Heat is transferred steadily to the boiling water in the pan through its  $0.5\text{-cm-thick}$  flat bottom at a rate of  $800 \text{ W}$ . If the inner surface temperature of the bottom of the pan is  $108^\circ\text{C}$ , determine (a) the boiling heat transfer coefficient on the inner surface of the pan and (b) the outer surface temperature of the bottom of the pan.

**3-21** A cylindrical resistor element on a circuit board dissipates  $0.15 \text{ W}$  of power in an environment at  $40^\circ\text{C}$ . The resistor is  $1.2 \text{ cm}$  long, and has a diameter of  $0.3 \text{ cm}$ . Assuming heat to be transferred uniformly from all surfaces, determine (a) the amount of heat this resistor dissipates during a  $24\text{-h}$  period; (b) the heat flux on the surface of the resistor, in  $\text{W/m}^2$ ; and (c) the surface temperature of the resistor for a combined convection and radiation heat transfer coefficient of  $9 \text{ W/m}^2\cdot\text{K}$ .

**3-22** Consider a power transistor that dissipates 0.2 W of power in an environment at 30°C. The transistor is 0.4 cm long and has a diameter of 0.5 cm. Assuming heat to be transferred uniformly from all surfaces, determine (a) the amount of heat this resistor dissipates during a 24-h period, in kWh; (b) the heat flux on the surface of the transistor, in W/m<sup>2</sup>; and (c) the surface temperature of the resistor for a combined convection and radiation heat transfer coefficient of 18 W/m<sup>2</sup>·K.

FIGURE P3-22

**3-23** A 1.0 m × 1.5 m double-pane window consists of two 4-mm-thick layers of glass ( $k = 0.78 \text{ W/m}\cdot\text{K}$ ) that are separated by a 5-mm air gap ( $k_{\text{air}} = 0.025 \text{ W/m}\cdot\text{K}$ ). The heat flow through the air gap is assumed to be by conduction. The inside and outside air temperatures are 20°C and -20°C, respectively, and the inside and outside heat transfer coefficients are 40 and 20 W/m<sup>2</sup>·K. Determine (a) the daily rate of heat loss through the window in steady operation and (b) the temperature difference across the largest thermal resistance.

**3-24** Consider a 1.2-m-high and 2-m-wide glass window whose thickness is 6 mm and thermal conductivity is  $k = 0.78 \text{ W/m}\cdot\text{K}$ . Determine the steady rate of heat transfer through this glass window and the temperature of its inner surface for a day during which the room is maintained at 24°C while the temperature of the outdoors is -5°C. Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 25 \text{ W/m}^2\cdot\text{K}$ , and disregard any heat transfer by radiation.

**3-25** Consider a 1.2-m-high and 2-m-wide double-pane window consisting of two 3-mm-thick layers of glass ( $k = 0.78 \text{ W/m}\cdot\text{K}$ ) separated by a 12-mm-wide stagnant air space ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ). Determine the steady rate of heat transfer through this double-pane window and the temperature of its inner surface for a day during which the room is maintained at 24°C while the temperature of the outdoors is -5°C. Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 25 \text{ W/m}^2\cdot\text{K}$ , and disregard any heat transfer by radiation.

Answers: 114 W, 19.2°C

FIGURE P3-25

**3-26** Repeat Prob. 3-25, assuming the space between the two glass layers is evacuated.

**3-27** Reconsider Prob. 3-25. Using EES (or other) software, plot the rate of heat transfer through the window as a function of the width of air space in the range of 2 mm to 20 mm, assuming pure conduction through the air. Discuss the results.

**3-28E** A wall is constructed of two layers of 0.7-in-thick sheetrock ( $k = 0.10 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ), which is a plasterboard made of two layers of heavy paper separated by a layer of gypsum, placed 7 in apart. The space between the sheetrocks is filled with fiberglass insulation ( $k = 0.020 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ). Determine (a) the thermal resistance of the wall and (b) its  $R$ -value of insulation in English units.

FIGURE P3-28E

**3-29** To defog the rear window of an automobile, a very thin transparent heating element is attached to the inner surface of

the window. A uniform heat flux of  $1300 \text{ W/m}^2$  is provided to the heating element for defogging a rear window with thickness of 5 mm. The interior temperature of the automobile is  $22^\circ\text{C}$  and the convection heat transfer coefficient is  $15 \text{ W/m}^2\cdot\text{K}$ . The outside ambient temperature is  $-5^\circ\text{C}$  and the convection heat transfer coefficient is  $100 \text{ W/m}^2\cdot\text{K}$ . If the thermal conductivity of the window is  $1.2 \text{ W/m}\cdot\text{K}$ , determine the inner surface temperature of the window.

FIGURE P3–29

**3–30** A transparent film is to be bonded onto the top surface of a solid plate inside a heated chamber. For the bond to cure properly, a temperature of  $70^\circ\text{C}$  is to be maintained at the bond, between the film and the solid plate. The transparent film has a thickness of 1 mm and thermal conductivity of  $0.05 \text{ W/m}\cdot\text{K}$ , while the solid plate is 13 mm thick and has a thermal conductivity of  $1.2 \text{ W/m}\cdot\text{K}$ . Inside the heated chamber, the convection heat transfer coefficient is  $70 \text{ W/m}^2\cdot\text{K}$ . If the bottom surface of the solid plate is maintained at  $52^\circ\text{C}$ , determine the temperature inside the heated chamber and the surface temperature of the transparent film. Assume thermal contact resistance is negligible.

FIGURE P3–30

**3–31** To defrost ice accumulated on the outer surface of an automobile windshield, warm air is blown over the inner surface of the windshield. Consider an automobile windshield with thickness of 5 mm and thermal conductivity of

$1.4 \text{ W/m}\cdot\text{K}$ . The outside ambient temperature is  $-10^\circ\text{C}$ , and the convection heat transfer coefficient is  $200 \text{ W/m}^2\cdot\text{K}$ , while the ambient temperature inside the automobile is  $25^\circ\text{C}$ . Determine the value of the convection heat transfer coefficient for the warm air blowing over the inner surface of the windshield necessary to cause the accumulated ice to begin melting.

FIGURE P3–31

**3–32** An aluminum plate of 25 mm thick ( $k = 235 \text{ W/m}\cdot\text{K}$ ) is attached on a copper plate with thickness of 10 mm. The copper plate is heated electrically to dissipate a uniform heat flux of  $5300 \text{ W/m}^2$ . The upper surface of the aluminum plate is exposed to convection heat transfer in a condition such that the convection heat transfer coefficient is  $67 \text{ W/m}^2\cdot\text{K}$  and the surrounding room temperature is  $20^\circ\text{C}$ . Other surfaces of the two attached plates are insulated such that heat only dissipates through the upper surface of the aluminum plate. If the surface of the copper plate that is attached to the aluminum plate has a temperature of  $100^\circ\text{C}$ , determine the thermal contact conductance of the aluminum/copper interface.

FIGURE P3–32

**3–33** The roof of a house consists of a 15-cm-thick concrete slab ( $k = 2 \text{ W/m}\cdot\text{K}$ ) that is 15 m wide and 20 m long. The convection heat transfer coefficients on the inner and outer surfaces of the roof are 5 and  $12 \text{ W/m}^2\cdot\text{K}$ , respectively. On a clear winter night, the ambient air is reported to be at  $10^\circ\text{C}$ , while the night sky temperature is  $100 \text{ K}$ . The house and the interior surfaces of the wall are maintained at a constant temperature of  $20^\circ\text{C}$ . The emissivity of both surfaces of the concrete roof

is 0.9. Considering both radiation and convection heat transfers, determine the rate of heat transfer through the roof, and the inner surface temperature of the roof.

If the house is heated by a furnace burning natural gas with an efficiency of 80 percent, and the price of natural gas is \$1.20/therm (1 therm = 105,500 kJ of energy content), determine the money lost through the roof that night during a 14-h period.

**FIGURE P3–33**

**3–34** A  $2\text{ m} \times 1.5\text{ m}$  section of wall of an industrial furnace burning natural gas is not insulated, and the temperature at the outer surface of this section is measured to be  $80^\circ\text{C}$ . The temperature of the furnace room is  $30^\circ\text{C}$ , and the combined convection and radiation heat transfer coefficient at the surface of the outer furnace is  $10\text{ W/m}^2\text{-K}$ . It is proposed to insulate this section of the furnace wall with glass wool insulation ( $k = 0.038\text{ W/m-K}$ ) in order to reduce the heat loss by 90 percent. Assuming the outer surface temperature of the metal section still remains at about  $110^\circ\text{C}$ , determine the thickness of the insulation that needs to be used.

The furnace operates continuously and has an efficiency of 78 percent. The price of the natural gas is \$1.10/therm (1 therm = 105,500 kJ of energy content). If the installation of the insulation will cost \$250 for materials and labor, determine how long it will take for the insulation to pay for itself from the energy it saves.

**3–35** The wall of a refrigerator is constructed of fiberglass insulation ( $k = 0.035\text{ W/m-K}$ ) sandwiched between two layers of 1-mm-thick sheet metal ( $k = 15.1\text{ W/m-K}$ ). The refrigerated space is maintained at  $3^\circ\text{C}$ , and the average heat transfer coefficients at the inner and outer surfaces of the wall are  $4\text{ W/m}^2\text{-K}$  and  $9\text{ W/m}^2\text{-K}$ , respectively. The kitchen temperature averages  $25^\circ\text{C}$ . It is observed that condensation occurs on the outer surfaces of the refrigerator when the temperature of the outer surface drops to  $20^\circ\text{C}$ . Determine the minimum thickness of fiberglass insulation that needs to be used in the wall in order to avoid condensation on the outer surfaces.

**FIGURE P3–35**

**3–36** Reconsider Prob. 3–35. Using EES (or other) software, investigate the effects of the thermal conductivities of the insulation material and the sheet metal on the thickness of the insulation. Let the thermal conductivity vary from  $0.02\text{ W/m-K}$  to  $0.08\text{ W/m-K}$  for insulation and  $10\text{ W/m-K}$  to  $400\text{ W/m-K}$  for sheet metal. Plot the thickness of the insulation as the functions of the thermal conductivities of the insulation and the sheet metal, and discuss the results.

**3–37** Heat is to be conducted along a circuit board that has a copper layer on one side. The circuit board is  $15\text{ cm}$  long and  $15\text{ cm}$  wide, and the thicknesses of the copper and epoxy layers are  $0.1\text{ mm}$  and  $1.2\text{ mm}$ , respectively. Disregarding heat transfer from side surfaces, determine the percentages of heat conduction along the copper ( $k = 386\text{ W/m-K}$ ) and epoxy ( $k = 0.26\text{ W/m-K}$ ) layers. Also determine the effective thermal conductivity of the board.

*Answers: 0.8 percent, 99.2 percent, and  $29.9\text{ W/m-K}$*

**3–38E** A  $0.03\text{-in-thick}$  copper plate ( $k = 223\text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) is sandwiched between two  $0.15\text{-in-thick}$  epoxy boards ( $k = 0.15\text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) that are  $7\text{ in} \times 9\text{ in}$  in size. Determine the effective thermal conductivity of the board along its  $9\text{-in-long}$  side. What fraction of the heat conducted along that side is conducted through copper?

**FIGURE P3–38E**

**3-39** Consider a house that has a  $10\text{-m} \times 20\text{-m}$  base and a 4-m-high wall. All four walls of the house have an  $R$ -value of  $2.31 \text{ m}^2\cdot^\circ\text{C}/\text{W}$ . The two  $10\text{-m} \times 4\text{-m}$  walls have no windows. The third wall has five windows made of 0.5-cm-thick glass ( $k = 0.78 \text{ W/m}\cdot\text{K}$ ),  $1.2 \text{ m} \times 1.8 \text{ m}$  in size. The fourth wall has the same size and number of windows, but they are double-paned with a 1.5-cm-thick stagnant air space ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ) enclosed between two 0.5-cm-thick glass layers. The thermostat in the house is set at  $24^\circ\text{C}$  and the average temperature outside at that location is  $8^\circ\text{C}$  during the seven-month-long heating season. Disregarding any direct radiation gain or loss through the windows and taking the heat transfer coefficients at the inner and outer surfaces of the house to be 7 and  $18 \text{ W/m}^2\cdot\text{K}$ , respectively, determine the average rate of heat transfer through each wall.

If the house is electrically heated and the price of electricity is  $\$0.08/\text{kWh}$ , determine the amount of money this household will save per heating season by converting the single-pane windows to double-pane windows.

**3-40E** Consider a house whose walls are 12 ft high and 40 ft long. Two of the walls of the house have no windows, while each of the other two walls has four windows made of 0.25-in-thick glass ( $k = 0.45 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ ),  $3 \text{ ft} \times 5 \text{ ft}$  in size. The walls are certified to have an  $R$ -value of 19 (i.e., an  $L/k$  value of  $19 \text{ h}\cdot\text{ft}^2\cdot{}^\circ\text{F}/\text{Btu}$ ). Disregarding any direct radiation gain or loss through the windows and taking the heat transfer coefficients at the inner and outer surfaces of the house to be 2 and  $4 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ , respectively, determine the ratio of the heat transfer through the walls with and without windows.

FIGURE P3-40E

**3-41** **PtD** The outer surface of an engine is situated in a place where oil leakage can occur. When leaked oil comes in contact with a hot surface that has a temperature above its autoignition temperature, the oil can ignite spontaneously. Consider an engine cover that is made of a stainless steel plate with a thickness of 1 cm and a thermal conductivity of  $14 \text{ W/m}\cdot\text{K}$ . The inner surface of the engine cover is exposed to hot air with a convection heat transfer coefficient of  $7 \text{ W/m}^2\cdot\text{K}$  at  $333^\circ\text{C}$ . The outer surface is exposed to an environment where the ambient air is  $69^\circ\text{C}$  with a convection heat transfer coefficient of  $7 \text{ W/m}^2\cdot\text{K}$ . To prevent fire hazard in the event of oil leak on the engine cover, a layer of thermal barrier coating (TBC) with a thermal conductivity of  $1.1 \text{ W/m}\cdot\text{K}$  is applied on

the engine cover outer surface. Would a TBC layer of 4 mm in thickness be sufficient to keep the engine cover surface below autoignition temperature of  $200^\circ\text{C}$  to prevent fire hazard?

FIGURE P3-41

**3-42** **PtD** Heat dissipated from a machine in operation can cause hot spots on its surface. Exposed hot spots can cause thermal burns when in contact with human skin tissue and are considered to be hazards at the workplace. Consider a machine surface that is made of a 5-mm thick aluminum with a thermal conductivity of  $237 \text{ W/m}\cdot\text{K}$ . During operation the machine dissipates about  $300 \text{ W/m}^2$  of heat to the surroundings, and the inner aluminum surface is at  $150^\circ\text{C}$ . To prevent machine operators from thermal burns, the machine surface can be covered with insulation. The aluminum/insulation interface has a thermal contact conductance of  $3000 \text{ W/m}^2\cdot\text{K}$ . What is the thickness required for the insulation layer with a thermal conductivity of  $0.06 \text{ W/m}\cdot\text{K}$  in order to maintain the surface temperature at  $45^\circ\text{C}$  or lower?

FIGURE P3-42

### Thermal Contact Resistance

**3-43C** What is thermal contact resistance? How is it related to thermal contact conductance?

**3-44C** Will the thermal contact resistance be greater for smooth or rough plain surfaces?

**3-45C** Explain how the thermal contact resistance can be minimized.

**3-46C** A wall consists of two layers of insulation pressed against each other. Do we need to be concerned about the thermal contact resistance at the interface in a heat transfer analysis or can we just ignore it?

**3-47C** A plate consists of two thin metal layers pressed against each other. Do we need to be concerned about the thermal contact resistance at the interface in a heat transfer analysis or can we just ignore it?

**3-48C** Consider two surfaces pressed against each other. Now the air at the interface is evacuated. Will the thermal contact resistance at the interface increase or decrease as a result?

**3-49** The thermal contact conductance at the interface of two 1-cm-thick copper plates is measured to be 18,000 W/m<sup>2</sup>·K. Determine the thickness of the copper plate whose thermal resistance is equal to the thermal resistance of the interface between the plates.

**3-50** Two 5-cm-diameter, 15-cm-long aluminum bars ( $k = 176$  W/m·K) with ground surfaces are pressed against each other with a pressure of 20 atm. The bars are enclosed in an insulation sleeve and, thus, heat transfer from the lateral surfaces is negligible. If the top and bottom surfaces of the two-bar system are maintained at temperatures of 150°C and 20°C, respectively, determine (a) the rate of heat transfer along the cylinders under steady conditions and (b) the temperature drop at the interface. *Answers: (a) 142.4 W, (b) 6.4°C*

**3-51** A 1-mm-thick copper plate ( $k = 386$  W/m·K) is sandwiched between two 5-mm-thick epoxy boards ( $k = 0.26$  W/m·K) that are 15 cm × 20 cm in size. If the thermal contact conductance on both sides of the copper plate is estimated to be 6000 W/m·K, determine the error involved in the total thermal resistance of the plate if the thermal contact conductances are ignored.

**FIGURE P3-51**

**3-52** Two identical aluminum plates with thickness of 30 cm are pressed against each other at an average pressure of 1 atm. The interface, sandwiched between the two plates, is filled with glycerin. On the left outer surface, it is subjected to a uniform heat flux of 7800 W/m<sup>2</sup> at a constant temperature of 50°C. On the right outer surface, the temperature is maintained

constant at 30°C. Determine the thermal contact conductance of the glycerin at the interface, if the thermal conductivity of the aluminum plates is 237 W/m·K. Discuss whether the value of the thermal contact conductance is reasonable or not.

**3-53** A two-layer wall is made of two metal plates, with surface roughness of about 25 μm, pressed together at an average pressure of 10 MPa. The first layer is a stainless steel plate with a thickness of 5 mm and a thermal conductivity of 14 W/m·K. The second layer is an aluminum plate with a thickness of 15 mm and a thermal conductivity of 237 W/m·K. On the stainless steel side of the wall, the surface is subjected to a heat flux of 800 W/m<sup>2</sup>. On the aluminum side of the wall, the surface experiences convection heat transfer at an ambient temperature of 20°C, where the convection coefficient is 12 W/m<sup>2</sup>·K. Determine the surface temperature of the stainless steel plate.

**3-54** An aluminum plate and a stainless steel plate are pressed against each other at an average pressure of 20 MPa. Both plates have a surface roughness of 2 μm. Determine the impact on the temperature drop at the interface if the surface roughness of the plates is increased by tenfold.

**3-55** A thin electronic component with a surface area of 950 cm<sup>2</sup> is cooled by having a heat sink attached on its top surface. The thermal contact conductance of the interface between the electronic component and the heat sink is 25,000 W/m<sup>2</sup>·K. According to the manufacturer, the heat sink has combined convection and radiation thermal resistance of 1.3 K/W. If the electronic component dissipates 45 W of heat through the heat sink in a surrounding temperature of 30°C, determine the temperature of the electronic component. Does the contact resistance at the interface of the electronic component and the heat sink play a significant role in the heat dissipation?

**3-56** Consider an engine cover that is made with two layers of metal plates. The inner layer is stainless steel ( $k_1 = 14$  W/m·K) with a thickness of 10 mm, and the outer layer is aluminum ( $k_2 = 237$  W/m·K) with a thickness of 5 mm. Both metal plates have a surface roughness of about 23 μm. The aluminum plate is attached on the stainless steel plate by screws that exert an average pressure of 20 MPa at the interface. The inside stainless steel surface of the cover is exposed to heat from the engine with a convection heat transfer coefficient of 10 W/m<sup>2</sup>·K at an ambient temperature of 150°C. The outside aluminum surface is exposed to a convection heat transfer coefficient of 25 W/m<sup>2</sup>·K at an ambient temperature of 40°C. Determine the heat flux through the engine cover.

**3-57** Inconel® refers to a class of nickel-chromium-based superalloys that are used in high-temperature applications, such as gas turbine blades. For further improvement in the performance of gas turbine engine, the outer blade surface is coated with ceramic-based thermal barrier coating (TBC). Consider a flat Inconel® plate, with a thickness of 12 mm, is coated with a layer of TBC, with a thickness of 300 μm, on its surface. At the interface between the Inconel® and the TBC, the thermal contact conductance is 10,500 W/m<sup>2</sup>·K. The thermal conductivities of the Inconel® and the TBC are 25 W/m·K and 1.5 W/m·K, respectively. The plate is in a surrounding of hot combustion

gasses at 1500°C, and the convection heat transfer coefficient is 750 W/m<sup>2</sup>·K. Determine the temperature at the mid-plane of the Inconel® plate, if the outer surface temperature is 1200°C.

### Generalized Thermal Resistance Networks

**3–58C** What are the two approaches used in the development of the thermal resistance network for two-dimensional problems?

**3–59C** The thermal resistance networks can also be used approximately for multidimensional problems. For what kind of multidimensional problems will the thermal resistance approach give adequate results?

**3–60C** When plotting the thermal resistance network associated with a heat transfer problem, explain when two resistances are in series and when they are in parallel.

**3–61** A 10-cm-thick wall is to be constructed with 2.5-m-long wood studs ( $k = 0.11 \text{ W/m}\cdot\text{K}$ ) that have a cross section of 10 cm × 10 cm. At some point the builder ran out of those studs and started using pairs of 2.5-m-long wood studs that have a cross section of 5 cm × 10 cm nailed to each other instead. The manganese steel nails ( $k = 50 \text{ W/m}\cdot\text{K}$ ) are 10 cm long and have a diameter of 0.4 cm. A total of 50 nails are used to connect the two studs, which are mounted to the wall such that the nails cross the wall. The temperature difference between the inner and outer surfaces of the wall is 8°C. Assuming the thermal contact resistance between the two layers to be negligible, determine the rate of heat transfer (a) through a solid stud and (b) through a stud pair of equal length and width nailed to each other. (c) Also determine the effective conductivity of the nailed stud pair.

**3–62E** Consider a 6-in × 8-in epoxy glass laminate ( $k = 0.10 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) whose thickness is 0.05 in. In order to reduce the thermal resistance across its thickness, cylindrical copper fillings ( $k = 223 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) of 0.02 in diameter are to be planted throughout the board, with a center-to-center distance of 0.06 in. Determine the new value of the thermal resistance of the epoxy board for heat conduction across its thickness as a result of this modification. *Answer: 0.00064 h·°F/Btu*

FIGURE P3–62E

**3–63** Clothing made of several thin layers of fabric with trapped air in between, often called ski clothing, is commonly used in cold climates because it is light, fashionable, and a very effective thermal insulator. So it is no surprise that such clothing has largely replaced thick and heavy old-fashioned coats.

Consider a jacket made of five layers of 0.1-mm-thick synthetic fabric ( $k = 0.13 \text{ W/m}\cdot\text{K}$ ) with 1.5-mm-thick air space ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ) between the layers. Assuming the inner surface temperature of the jacket to be 28°C and the surface area to be 1.25 m<sup>2</sup>, determine the rate of heat loss through the jacket when the temperature of the outdoors is 0°C and the heat transfer coefficient at the outer surface is 25 W/m<sup>2</sup>·K.

What would your response be if the jacket is made of a single layer of 0.5-mm-thick synthetic fabric? What should be the thickness of a wool fabric ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ) if the person is to achieve the same level of thermal comfort wearing a thick wool coat instead of a five-layer ski jacket?

**3–64** A 5-m-wide, 4-m-high, and 40-m-long kiln used to cure concrete pipes is made of 20-cm-thick concrete walls and ceiling ( $k = 0.9 \text{ W/m}\cdot\text{K}$ ). The kiln is maintained at 40°C by injecting hot steam into it. The two ends of the kiln, 4 m × 5 m in size, are made of a 3-mm-thick sheet metal covered with 2-cm-thick Styrofoam ( $k = 0.033 \text{ W/m}\cdot\text{K}$ ). The convection

FIGURE P3–64

heat transfer coefficients on the inner and the outer surfaces of the kiln are 3000 W/m<sup>2</sup>·K and 25 W/m<sup>2</sup>·K, respectively. Disregarding any heat loss through the floor, determine the rate of heat loss from the kiln when the ambient air is at -4°C.

**3–65** Reconsider Prob. 3–64. Using EES (or other) software, investigate the effects of the thickness of the wall and the convection heat transfer coefficient on the outer surface of the rate of heat loss from the kiln. Let the thickness vary from 10 cm to 30 cm and the convection heat transfer coefficient from 5 W/m<sup>2</sup>·K to 50 W/m<sup>2</sup>·K. Plot the rate of heat transfer as functions of wall thickness and the convection heat transfer coefficient, and discuss the results.

**3–66** A typical section of a building wall is shown in Fig. P3–66. This section extends in and out of the page and is repeated in the vertical direction. The wall support members

are made of steel ( $k = 50 \text{ W/m}\cdot\text{K}$ ). The support members are  $8 \text{ cm} (t_{23}) \times 0.5 \text{ cm} (L_B)$ . The remainder of the inner wall space is filled with insulation ( $k = 0.03 \text{ W/m}\cdot\text{K}$ ) and measures  $8 \text{ cm} (t_{23}) \times 60 \text{ cm} (L_B)$ . The inner wall is made of gypsum board ( $k = 0.5 \text{ W/m}\cdot\text{K}$ ) that is  $1 \text{ cm}$  thick ( $t_{12}$ ) and the outer wall is made of brick ( $k = 1.0 \text{ W/m}\cdot\text{K}$ ) that is  $10 \text{ cm}$  thick ( $t_{34}$ ). What is the average heat flux through this wall when  $T_1 = 20^\circ\text{C}$  and  $T_4 = 35^\circ\text{C}$ ?

FIGURE P3-66

**3-67** A 4-m-high and 6-m-wide wall consists of a long  $18\text{-cm} \times 30\text{-cm}$  cross section of horizontal bricks ( $k = 0.72 \text{ W/m}\cdot\text{K}$ ) separated by  $3\text{-cm}$ -thick plaster layers ( $k = 0.22 \text{ W/m}\cdot\text{K}$ ). There are also  $2\text{-cm}$ -thick plaster layers on each side of the wall, and a  $2\text{-cm}$ -thick rigid foam ( $k = 0.026 \text{ W/m}\cdot\text{K}$ ) on the inner side of the wall. The indoor and the outdoor temperatures are  $22^\circ\text{C}$  and  $-4^\circ\text{C}$ , and the convection heat transfer coefficients on the inner and the outer sides are  $h_1 = 10 \text{ W/m}^2\cdot\text{K}$  and  $h_2 = 20 \text{ W/m}^2\cdot\text{K}$ , respectively. Assuming one-dimensional heat transfer and disregarding radiation, determine the rate of heat transfer through the wall.

FIGURE P3-67

**3-68** Reconsider Prob. 3-67. Using EES (or other) software, plot the rate of heat transfer through the wall as a function of the thickness of the rigid foam in the range of  $1 \text{ cm}$  to  $10 \text{ cm}$ . Discuss the results.

**3-69** A 12-m-long and 5-m-high wall is constructed of two layers of  $1\text{-cm}$ -thick sheetrock ( $k = 0.17 \text{ W/m}\cdot\text{K}$ ) spaced  $16 \text{ cm}$  by wood studs ( $k = 0.11 \text{ W/m}\cdot\text{K}$ ) whose cross section is  $16 \text{ cm} \times 5 \text{ cm}$ . The studs are placed vertically  $60 \text{ cm}$  apart, and the space between them is filled with fiberglass insulation ( $k = 0.034 \text{ W/m}\cdot\text{K}$ ). The house is maintained at  $20^\circ\text{C}$  and the ambient temperature outside is  $-9^\circ\text{C}$ . Taking the heat transfer coefficients at the inner and outer surfaces of the house to be  $8.3$  and  $34 \text{ W/m}^2\cdot\text{K}$ , respectively, determine (a) the thermal resistance of the wall considering a representative section of it and (b) the rate of heat transfer through the wall.

**3-70E** A 10-in-thick, 30-ft-long, and 10-ft-high wall is to be constructed using 9-in-long solid bricks ( $k = 0.40 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) of cross section  $7 \text{ in} \times 7 \text{ in}$ , or identical size bricks with nine square air holes ( $k = 0.015 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) that are  $9 \text{ in}$  long and have a cross section of  $1.5 \text{ in} \times 1.5 \text{ in}$ . There is a  $0.5\text{-in}$ -thick plaster layer ( $k = 0.10 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) between two adjacent bricks on all four sides and on both sides of the wall. The house is maintained at  $80^\circ\text{F}$  and the ambient temperature outside is  $30^\circ\text{F}$ . Taking the heat transfer coefficients at the inner and outer surfaces of the wall to be  $1.5$  and  $4 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ , respectively, determine the rate of heat transfer through the wall constructed of (a) solid bricks and (b) bricks with air holes.

FIGURE P3-70E

**3-71** Consider a 5-m-high, 8-m-long, and  $0.22\text{-m}$ -thick wall whose representative cross section is as given in the figure. The thermal conductivities of various materials used, in  $\text{W/m}\cdot\text{K}$ , are  $k_A = k_F = 2$ ,  $k_B = 8$ ,  $k_C = 20$ ,  $k_D = 15$ , and  $k_E = 35$ . The left and right surfaces of the wall are maintained at uniform temperatures of  $300^\circ\text{C}$  and  $100^\circ\text{C}$ , respectively. Assuming heat transfer through the wall to be one-dimensional, determine

(a) the rate of heat transfer through the wall; (b) the temperature at the point where the sections *B*, *D*, and *E* meet; and (c) the temperature drop across the section *F*. Disregard any contact resistances at the interfaces.

FIGURE P3-71

**3-72** In an experiment to measure convection heat transfer coefficients, a very thin metal foil of very low emissivity (e.g., highly polished copper) is attached on the surface of a slab of material with very low thermal conductivity. The other surface of the metal foil is exposed to convection heat transfer by flowing fluid over the foil surface. This setup diminishes heat conduction through the slab and radiation on the metal foil surface, while heat convection plays the prominent role. The slab on which the metal foil is attached to has a thickness of 25 mm and a thermal conductivity of 0.023 W/m·K. In a condition where the surrounding room temperature is 20°C, the metal foil is heated electrically with a uniform heat flux of 5000 W/m<sup>2</sup>. If the bottom surface of the slab is 20°C and the metal foil has an emissivity of 0.02, determine (a) the convection heat transfer coefficient if air is flowing over the metal foil and the surface temperature of the foil is 150°C; and (b) the convection heat transfer coefficient if water is flowing over the metal foil and the surface temperature of the foil is 30°C.

FIGURE P3-72

### Heat Conduction in Cylinders and Spheres

**3-73C** What is an infinitely long cylinder? When is it proper to treat an actual cylinder as being infinitely long, and when is it not?

**3-74C** Can the thermal resistance concept be used for a solid cylinder or sphere in steady operation? Explain.

**3-75C** Consider a short cylinder whose top and bottom surfaces are insulated. The cylinder is initially at a uniform temperature  $T_i$  and is subjected to convection from its side surface to a medium at temperature  $T_\infty$ , with a heat transfer coefficient of  $h$ . Is the heat transfer in this short cylinder one- or two-dimensional? Explain.

**3-76** Steam at 320°C flows in a stainless steel pipe ( $k = 15 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are 5 cm and 5.5 cm, respectively. The pipe is covered with 3-cm-thick glass wool insulation ( $k = 0.038 \text{ W/m}\cdot\text{K}$ ). Heat is lost to the surroundings at 5°C by natural convection and radiation, with a combined natural convection and radiation heat transfer coefficient of 15 W/m<sup>2</sup>·K. Taking the heat transfer coefficient inside the pipe to be 80 W/m<sup>2</sup>·K, determine the rate of heat loss from the steam per unit length of the pipe. Also determine the temperature drops across the pipe shell and the insulation.

**3-77** Reconsider Prob. 3-76. Using EES (or other) software, investigate the effect of the thickness of the insulation on the rate of heat loss from the steam and the temperature drop across the insulation layer. Let the insulation thickness vary from 1 cm to 10 cm. Plot the rate of heat loss and the temperature drop as a function of insulation thickness, and discuss the results.

**3-78** A 50-m-long section of a steam pipe whose outer diameter is 10 cm passes through an open space at 15°C. The average temperature of the outer surface of the pipe is measured to be 150°C. If the combined heat transfer coefficient on the outer surface of the pipe is 20 W/m<sup>2</sup>·K, determine (a) the rate of heat loss from the steam pipe; (b) the annual cost of this energy lost if steam is generated in a natural gas furnace that has an efficiency of 75 percent and the price of natural gas is \$0.52/therm (1 therm = 105,500 kJ); and (c) the thickness of fiberglass insulation ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ) needed in order to save 90 percent of the heat lost. Assume the pipe temperature to remain constant at 150°C.

FIGURE P3-78

**3–79** Superheated steam at an average temperature  $200^\circ\text{C}$  is transported through a steel pipe ( $k = 50 \text{ W/m}\cdot\text{K}$ ,  $D_o = 8.0 \text{ cm}$ ,  $D_i = 6.0 \text{ cm}$ , and  $L = 20.0 \text{ m}$ ). The pipe is insulated with a 4-cm thick layer of gypsum plaster ( $k = 0.5 \text{ W/m}\cdot\text{K}$ ). The insulated pipe is placed horizontally inside a warehouse where the average air temperature is  $10^\circ\text{C}$ . The steam and the air heat transfer coefficients are estimated to be  $800$  and  $200 \text{ W/m}^2\cdot\text{K}$ , respectively. Calculate (a) the daily rate of heat transfer from the superheated steam, and (b) the temperature on the outside surface of the gypsum plaster insulation.

**3–80E** Steam exiting the turbine of a steam power plant at  $100^\circ\text{F}$  is to be condensed in a large condenser by cooling water flowing through copper pipes ( $k = 223 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ ) of inner diameter  $0.4 \text{ in}$  and outer diameter  $0.6 \text{ in}$  at an average temperature of  $70^\circ\text{F}$ . The heat of vaporization of water at  $100^\circ\text{F}$  is  $1037 \text{ Btu/lbm}$ . The heat transfer coefficients are  $1500 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$  on the steam side and  $35 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^\circ\text{F}$  on the water side. Determine the length of the tube required to condense steam at a rate of  $120 \text{ lbm/h}$ . *Answer: 1150 ft*

**FIGURE P3–80E**

**3–81E** Repeat Prob. 3–80E, assuming that a  $0.01\text{-in}$ -thick layer of mineral deposit ( $k = 0.5 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$ ) has formed on the inner surface of the pipe.

**3–82** Reconsider Prob. 3–80E. Using EES (or other) software, investigate the effects of the thermal conductivity of the pipe material and the outer diameter of the pipe on the length of the tube required. Let the thermal conductivity vary from  $10 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$  to  $400 \text{ Btu/h}\cdot\text{ft}\cdot{}^\circ\text{F}$  and the outer diameter from  $0.5 \text{ in}$  to  $1.0 \text{ in}$ . Plot the length of the tube as functions of pipe conductivity and the outer pipe diameter, and discuss the results.

**3–83** A  $2.2\text{-mm}$ -diameter and  $10\text{-m}$ -long electric wire is tightly wrapped with a  $1\text{-mm}$ -thick plastic cover whose thermal conductivity is  $k = 0.15 \text{ W/m}\cdot\text{K}$ . Electrical measurements indicate that a current of  $13 \text{ A}$  passes through the wire and there is a voltage drop of  $8 \text{ V}$  along the wire. If the insulated

wire is exposed to a medium at  $T_\infty = 30^\circ\text{C}$  with a heat transfer coefficient of  $h = 24 \text{ W/m}^2\cdot\text{K}$ , determine the temperature at the interface of the wire and the plastic cover in steady operation. Also determine if doubling the thickness of the plastic cover will increase or decrease this interface temperature.

**FIGURE P3–83**

**3–84** Consider a  $2\text{-m}$ -high electric hot-water heater that has a diameter of  $40 \text{ cm}$  and maintains the hot water at  $55^\circ\text{C}$ . The tank is located in a small room whose average temperature is  $27^\circ\text{C}$ , and the heat transfer coefficients on the inner and outer surfaces of the heater are  $50$  and  $12 \text{ W/m}^2\cdot\text{K}$ , respectively. The tank is placed in another  $46\text{-cm}$ -diameter sheet metal tank of negligible thickness, and the space between the two tanks is filled with foam insulation ( $k = 0.03 \text{ W/m}\cdot\text{K}$ ). The thermal resistances of the water tank and the outer thin sheet metal shell

**FIGURE P3–84**

are very small and can be neglected. The price of electricity is  $\$0.08/\text{kWh}$ , and the home owner pays  $\$280$  a year for water heating. Determine the fraction of the hot-water energy cost of this household that is due to the heat loss from the tank.

Hot-water tank insulation kits consisting of  $3\text{-cm}$ -thick fiberglass insulation ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ) large enough to wrap the entire tank are available in the market for about  $\$30$ . If such an insulation is installed on this water tank by the home owner himself, how long will it take for this additional insulation to pay for itself? *Answers: 17.2 percent, 19 months*

**3-85** Chilled water enters a thin-shelled 5-cm-diameter, 150-m-long pipe at 7°C at a rate of 0.98 kg/s and leaves at 8°C. The pipe is exposed to ambient air at 30°C with a heat transfer coefficient of 9 W/m<sup>2</sup>·K. If the pipe is to be insulated with glass wool insulation ( $k = 0.05 \text{ W/m}\cdot\text{K}$ ) in order to decrease the temperature rise of water to 0.25°C, determine the required thickness of the insulation.

**3-86E** Steam at 450°F is flowing through a steel pipe ( $k = 8.7 \text{ Btu/h}\cdot\text{ft}^{-2}\cdot\text{F}^{-1}$ ) whose inner and outer diameters are 3.5 in and 4.0 in, respectively, in an environment at 55°F. The pipe is insulated with 2-in-thick fiberglass insulation ( $k = 0.020 \text{ Btu/h}\cdot\text{ft}^{-2}\cdot\text{F}^{-1}$ ). If the heat transfer coefficients on the inside and the outside of the pipe are 30 and 5 Btu/h·ft<sup>2</sup>·F, respectively, determine the rate of heat loss from the steam per foot length of the pipe. What is the error involved in neglecting the thermal resistance of the steel pipe in calculations?

**3-87** Hot water at an average temperature of 70°C is flowing through a 15-m section of a cast iron pipe ( $k = 52 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are 4 cm and 4.6 cm, respectively. The outer surface of the pipe, whose emissivity is 0.7, is exposed to the cold air at 10°C in the basement, with a heat transfer coefficient of 15 W/m<sup>2</sup>·K. The heat transfer coefficient at the inner surface of the pipe is 120 W/m<sup>2</sup>·K. Taking the walls of the basement to be at 10°C also, determine the rate of heat loss from the hot water. Also, determine the average velocity of the water in the pipe if the temperature of the water drops by 3°C as it passes through the basement.

**3-88** In a pharmaceutical plant, a copper pipe ( $k_c = 400 \text{ W/m}\cdot\text{K}$ ) with inner diameter of 20 mm and wall thickness of 2.5 mm is used for carrying liquid oxygen to a storage tank. The liquid oxygen flowing in the pipe has an average temperature of -200°C and a convection heat transfer coefficient of 120 W/m<sup>2</sup>·K. The condition surrounding the pipe has an ambient air temperature of 20°C and a combined heat transfer coefficient of 20 W/m<sup>2</sup>·K. If the dew point is 10°C, determine the thickness of the insulation ( $k_i = 0.05 \text{ W/m}\cdot\text{K}$ ) around the copper pipe to avoid condensation on the outer surface. Assume thermal contact resistance is negligible.

FIGURE P3-88

**3-89** Liquid hydrogen is flowing through an insulated pipe ( $k = 23 \text{ W/m}\cdot\text{K}$ ,  $D_i = 3 \text{ cm}$ ,  $D_o = 4 \text{ cm}$ , and  $L = 20 \text{ m}$ ). The pipe is situated in a chemical plant, where the average air temperature is 40°C. The convection heat transfer coefficients of the liquid hydrogen and the ambient air are 200 W/m<sup>2</sup>·K and 50 W/m<sup>2</sup>·K, respectively. If the outer surface temperature of the insulated pipe is 5°C, determine the thickness of the pipe insulation ( $k = 0.6 \text{ W/m}\cdot\text{K}$ ) in order to keep the liquid hydrogen flowing at an average temperature of -300°C.

**3-90** Exposure to high concentration of gaseous ammonia can cause lung damage. To prevent gaseous ammonia from leaking out, ammonia is transported in its liquid state through a pipe ( $k = 25 \text{ W/m}\cdot\text{K}$ ,  $D_i = 2.5 \text{ cm}$ ,  $D_o = 4 \text{ cm}$ , and  $L = 10 \text{ m}$ ). Since liquid ammonia has a normal boiling point of -33.3°C, the pipe needs to be properly insulated to prevent the surrounding heat from causing the ammonia to boil. The pipe is situated in a laboratory, where the average ambient air temperature is 20°C. The convection heat transfer coefficients of the liquid hydrogen and the ambient air are 100 W/m<sup>2</sup>·K and 20 W/m<sup>2</sup>·K, respectively. Determine the insulation thickness for the pipe using a material with  $k = 0.75 \text{ W/m}\cdot\text{K}$  to keep the liquid ammonia flowing at an average temperature of -35°C, while maintaining the insulated pipe outer surface temperature at 10°C.

**3-91** A mixture of chemicals is flowing in a pipe ( $k = 14 \text{ W/m}\cdot\text{K}$ ,  $D_i = 2.5 \text{ cm}$ ,  $D_o = 3 \text{ cm}$ , and  $L = 10 \text{ m}$ ). During the transport, the mixture undergoes an exothermic reaction having an average temperature of 135°C and a convection heat transfer coefficient of 150 W/m<sup>2</sup>·K. To prevent any incident of thermal burn, the pipe needs to be insulated. However, due to the vicinity of the pipe, there is only enough room to fit a 2.5-cm-thick layer of insulation over the pipe. The pipe is situated in a plant, where the average ambient air temperature is 20°C and the convection heat transfer coefficient is 25 W/m<sup>2</sup>·K. Determine the insulation for the pipe such that the thermal conductivity of the insulation is sufficient to maintain the outside surface temperature at 45°C or lower.

**3-92** Ice slurry is being transported in a pipe ( $k = 15 \text{ W/m}\cdot\text{K}$ ,  $D_i = 2.5 \text{ cm}$ ,  $D_o = 3 \text{ cm}$ , and  $L = 5 \text{ m}$ ) with an inner surface temperature of 0°C. The ambient condition surrounding the pipe has a temperature of 20°C, a convection heat transfer coefficient of 10 W/m<sup>2</sup>·K, and a dew point of 10°C. If the outer surface temperature of the pipe drops below the dew point, condensation can occur on the surface. Since this pipe is located in a vicinity of high voltage devices, water droplets from the condensation can cause electrical hazard. To prevent such incident, the pipe surface needs to be insulated. Determine the insulation thickness for the pipe using a material with  $k = 0.95 \text{ W/m}\cdot\text{K}$  to prevent the outer surface temperature from dropping below the dew point.

**3-93** An 8-m-internal-diameter spherical tank made of 1.5-cm-thick stainless steel ( $k = 15 \text{ W/m}\cdot\text{K}$ ) is used to store

iced water at  $0^{\circ}\text{C}$ . The tank is located in a room whose temperature is  $25^{\circ}\text{C}$ . The walls of the room are also at  $25^{\circ}\text{C}$ . The outer surface of the tank is black (emissivity  $\epsilon = 1$ ), and heat transfer between the outer surface of the tank and the surroundings is by natural convection and radiation. The convection heat transfer coefficients at the inner and the outer surfaces of the tank are  $80 \text{ W/m}^2\cdot\text{K}$  and  $10 \text{ W/m}^2\cdot\text{K}$ , respectively. Determine (a) the rate of heat transfer to the iced water in the tank and (b) the amount of ice at  $0^{\circ}\text{C}$  that melts during a 24-h period. The heat of fusion of water at atmospheric pressure is  $h_{if} = 333.7 \text{ kJ/kg}$ .

**FIGURE P3–93**

**3–94** The boiling temperature of nitrogen at atmospheric pressure at sea level (1 atm pressure) is  $-196^{\circ}\text{C}$ . Therefore, nitrogen is commonly used in low-temperature scientific studies since the temperature of liquid nitrogen in a tank open to the atmosphere will remain constant at  $-196^{\circ}\text{C}$  until it is depleted. Any heat transfer to the tank will result in the evaporation of some liquid nitrogen, which has a heat of vaporization of  $198 \text{ kJ/kg}$  and a density of  $810 \text{ kg/m}^3$  at 1 atm.

Consider a 3-m-diameter spherical tank that is initially filled with liquid nitrogen at 1 atm and  $-196^{\circ}\text{C}$ . The tank is exposed to ambient air at  $15^{\circ}\text{C}$ , with a combined convection and radiation heat transfer coefficient of  $35 \text{ W/m}^2\cdot\text{K}$ . The temperature of the

**FIGURE P3–94**

thin-shelled spherical tank is observed to be almost the same as the temperature of the nitrogen inside. Determine the rate of evaporation of the liquid nitrogen in the tank as a result of the heat transfer from the ambient air if the tank is (a) not insulated, (b) insulated with 5-cm-thick fiberglass insulation ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ), and (c) insulated with 2-cm-thick superinsulation which has an effective thermal conductivity of  $0.00005 \text{ W/m}\cdot\text{K}$ .

**3–95** Repeat Prob. 3–94 for liquid oxygen, which has a boiling temperature of  $-183^{\circ}\text{C}$ , a heat of vaporization of  $213 \text{ kJ/kg}$ , and a density of  $1140 \text{ kg/m}^3$  at 1 atm pressure.

### Critical Radius of Insulation

**3–96C** What is the critical radius of insulation? How is it defined for a cylindrical layer?

**3–97C** Consider an insulated pipe exposed to the atmosphere. Will the critical radius of insulation be greater on calm days or on windy days? Why?

**3–98C** A pipe is insulated to reduce the heat loss from it. However, measurements indicate that the rate of heat loss has increased instead of decreasing. Can the measurements be right?

**3–99C** Consider a pipe at a constant temperature whose radius is greater than the critical radius of insulation. Someone claims that the rate of heat loss from the pipe has increased when some insulation is added to the pipe. Is this claim valid?

**3–100C** A pipe is insulated such that the outer radius of the insulation is less than the critical radius. Now the insulation is taken off. Will the rate of heat transfer from the pipe increase or decrease for the same pipe surface temperature?

**3–101E** A 0.083-in-diameter electrical wire at  $90^{\circ}\text{F}$  is covered by 0.02-in-thick plastic insulation ( $k = 0.075 \text{ Btu/h}\cdot\text{ft}\cdot^{\circ}\text{F}$ ). The wire is exposed to a medium at  $50^{\circ}\text{F}$ , with a combined convection and radiation heat transfer coefficient of  $2.5 \text{ Btu/h}\cdot\text{ft}^2\cdot^{\circ}\text{F}$ . Determine if the plastic insulation on the wire will increase or decrease heat transfer from the wire. *Answer: It helps*

**3–102E** Repeat Prob. 3–101E, assuming a thermal contact resistance of  $0.001 \text{ h}\cdot\text{ft}^2\cdot^{\circ}\text{F/Btu}$  at the interface of the wire and the insulation.

**3–103** A 5-mm-diameter spherical ball at  $50^{\circ}\text{C}$  is covered by a 1-mm-thick plastic insulation ( $k = 0.13 \text{ W/m}\cdot\text{K}$ ). The ball is exposed to a medium at  $15^{\circ}\text{C}$ , with a combined convection and radiation heat transfer coefficient of  $20 \text{ W/m}^2\cdot\text{K}$ . Determine if the plastic insulation on the ball will help or hurt heat transfer from the ball.

**FIGURE P3–103**

- 3-104**  Reconsider Prob. 3-103. Using EES (or other) software, plot the rate of heat transfer from the ball as a function of the plastic insulation thickness in the range of 0.5 mm to 20 mm. Discuss the results.

### Heat Transfer from Finned Surfaces

- 3-105C** Hot air is to be cooled as it is forced to flow through the tubes exposed to atmospheric air. Fins are to be added in order to enhance heat transfer. Would you recommend attaching the fins inside or outside the tubes? Why? When would you recommend attaching fins both inside and outside the tubes?

- 3-106C** What is the reason for the widespread use of fins on surfaces?

- 3-107C** What is the difference between the fin effectiveness and the fin efficiency?

- 3-108C** The fins attached to a surface are determined to have an effectiveness of 0.9. Do you think the rate of heat transfer from the surface has increased or decreased as a result of the addition of these fins?

- 3-109C** Explain how the fins enhance heat transfer from a surface. Also, explain how the addition of fins may actually decrease heat transfer from a surface.

- 3-110C** How does the overall effectiveness of a finned surface differ from the effectiveness of a single fin?

- 3-111C** Hot water is to be cooled as it flows through the tubes exposed to atmospheric air. Fins are to be attached in order to enhance heat transfer. Would you recommend attaching the fins inside or outside the tubes? Why?

- 3-112C** Consider two finned surfaces that are identical except that the fins on the first surface are formed by casting or extrusion, whereas they are attached to the second surface afterwards by welding or tight fitting. For which case do you think the fins will provide greater enhancement in heat transfer? Explain.

- 3-113C** The heat transfer surface area of a fin is equal to the sum of all surfaces of the fin exposed to the surrounding medium, including the surface area of the fin tip. Under what conditions can we neglect heat transfer from the fin tip?

- 3-114C** Does the (a) efficiency and (b) effectiveness of a fin increase or decrease as the fin length is increased?

- 3-115C** Two pin fins are identical, except that the diameter of one of them is twice the diameter of the other. For which fin is the (a) fin effectiveness and (b) fin efficiency higher? Explain.

- 3-116C** Two plate fins of constant rectangular cross section are identical, except that the thickness of one of them is twice the thickness of the other. For which fin is the (a) fin effectiveness and (b) fin efficiency higher? Explain.

- 3-117C** Two finned surfaces are identical, except that the convection heat transfer coefficient of one of them is twice that of the other. For which finned surface is the (a) fin effectiveness and (b) fin efficiency higher? Explain.

- 3-118** Obtain a relation for the fin efficiency for a fin of constant cross-sectional area  $A_c$ , perimeter  $p$ , length  $L$ , and thermal conductivity  $k$  exposed to convection to a medium at  $T_\infty$  with a heat transfer coefficient  $h$ . Assume the fins are sufficiently long so that the temperature of the fin at the tip is nearly  $T_\infty$ . Take the temperature of the fin at the base to be  $T_b$  and neglect heat transfer from the fin tips. Simplify the relation for (a) a circular fin of diameter  $D$  and (b) rectangular fins of thickness  $t$ .

- 3-119** A 4-mm-diameter and 10-cm-long aluminum fin ( $k = 237 \text{ W/m}\cdot\text{K}$ ) is attached to a surface. If the heat transfer coefficient is  $12 \text{ W/m}^2\cdot\text{K}$ , determine the percent error in the rate of heat transfer from the fin when the infinitely long fin assumption is used instead of the adiabatic fin tip assumption.

FIGURE P3-119

- 3-120** Consider a very long rectangular fin attached to a flat surface such that the temperature at the end of the fin is essentially that of the surrounding air, i.e.  $20^\circ\text{C}$ . Its width is  $5.0 \text{ cm}$ ; thickness is  $1.0 \text{ mm}$ ; thermal conductivity is  $200 \text{ W/m}\cdot\text{K}$ ; and base temperature is  $40^\circ\text{C}$ . The heat transfer coefficient is  $20 \text{ W/m}^2\cdot\text{K}$ . Estimate the fin temperature at a distance of  $5.0 \text{ cm}$  from the base and the rate of heat loss from the entire fin.

- 3-121** A turbine blade made of a metal alloy ( $k = 17 \text{ W/m}\cdot\text{K}$ ) has a length of  $5.3 \text{ cm}$ , a perimeter of  $11 \text{ cm}$ , and a cross-sectional area of  $5.13 \text{ cm}^2$ . The turbine blade is exposed to hot gas from the combustion chamber at  $973^\circ\text{C}$  with a convection heat transfer coefficient of  $538 \text{ W/m}^2\cdot\text{K}$ . The base of the turbine blade maintains a constant temperature of  $450^\circ\text{C}$  and the tip is adiabatic. Determine the heat transfer rate to the turbine blade and temperature at the tip.

FIGURE P3-121

**3–122E** Consider a stainless steel spoon ( $k = 8.7 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ) partially immersed in boiling water at  $200^\circ\text{F}$  in a kitchen at  $75^\circ\text{F}$ . The handle of the spoon has a cross section of  $0.08 \text{ in} \times 0.5 \text{ in}$ , and extends 7 in in the air from the free surface of the water. If the heat transfer coefficient at the exposed surfaces of the spoon handle is  $3 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ , determine the temperature difference across the exposed surface of the spoon handle. State your assumptions. *Answer:  $124.6^\circ\text{F}$*

FIGURE P3–122E

**3–123E** Reconsider Prob. 3–122E. Using EES (or other) software, investigate the effects of the thermal conductivity of the spoon material and the length of its extension in the air on the temperature difference across the exposed surface of the spoon handle. Let the thermal conductivity vary from  $5 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  to  $225 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and the length from 5 in to 12 in. Plot the temperature difference as the functions of thermal conductivity and length, and discuss the results.

**3–124** A DC motor delivers mechanical power to a rotating stainless steel shaft ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ) with a length of 25 cm and a diameter of 25 mm. In a surrounding with ambient air temperature of  $20^\circ\text{C}$  and convection heat transfer coefficient of  $25 \text{ W/m}^2\cdot\text{K}$ , the surface area of the motor housing that is exposed to the ambient air is  $0.075 \text{ m}^2$ . The motor uses  $300 \text{ W}$  of electrical power and delivers 55% of it as mechanical power to rotate the stainless steel shaft. If the tip of the stainless steel shaft has a temperature of  $22^\circ\text{C}$ , determine the surface temperature of the motor housing. Assume the base temperature of the shaft is equal to the surface temperature of the motor housing.

FIGURE P3–124

**3–125** A plane wall with surface temperature of  $350^\circ\text{C}$  is attached with straight rectangular fins ( $k = 235 \text{ W/m}\cdot\text{K}$ ). The fins are exposed to an ambient air condition of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $154 \text{ W/m}^2\cdot\text{K}$ . Each fin has a length of 50 mm, a base of 5 mm thick and a width of 100 mm. Determine the efficiency, heat transfer rate, and effectiveness of each fin, using (a) Table 3–3 and (b) Figure 3–43.

FIGURE P3–125

**3–126** Two 3-m-long and 0.4-cm-thick cast iron ( $k = 52 \text{ W/m}\cdot\text{K}$ ) steam pipes of outer diameter 10 cm are connected to each other through two 1-cm-thick flanges of outer diameter 20 cm. The steam flows inside the pipe at an average temperature of  $200^\circ\text{C}$  with a heat transfer coefficient of  $180 \text{ W/m}^2\cdot\text{K}$ . The outer surface of the pipe is exposed to an ambient at  $12^\circ\text{C}$ , with a heat transfer coefficient of  $25 \text{ W/m}^2\cdot\text{K}$ . (a) Disregarding the flanges, determine the average outer surface temperature of the pipe. (b) Using this temperature for the base of the flange and treating the flanges as the fins, determine the fin efficiency and the rate of heat transfer from the flanges. (c) What length of pipe is the flange section equivalent to for heat transfer purposes?

FIGURE P3–126

**3–127** Pipes with inner and outer diameters of 50 mm and 60 mm, respectively, are used for transporting superheated vapor in a manufacturing plant. The pipes with thermal conductivity of  $16 \text{ W/m}\cdot\text{K}$  are connected together by flanges with combined thickness of 20 mm and outer diameter of 90 mm. Air condition surrounding the pipes has a temperature of  $25^\circ\text{C}$  and a convection

heat transfer coefficient of  $10 \text{ W/m}^2\text{-K}$ . If the inner surface temperature of the pipe is maintained at a constant temperature of  $150^\circ\text{C}$ , determine the temperature at the base of the flange and the rate of heat loss through the flange.

FIGURE P3–127

**3–128** Steam in a heating system flows through tubes whose outer diameter is 5 cm and whose walls are maintained at a temperature of  $180^\circ\text{C}$ . Circular aluminum alloy 2024-T6 fins ( $k = 186 \text{ W/m}\cdot\text{K}$ ) of outer diameter 6 cm and constant thickness 1 mm are attached to the tube. The space between the fins is 3 mm, and thus there are 250 fins per meter length of the tube. Heat is transferred to the surrounding air at  $T_\infty = 25^\circ\text{C}$ , with a heat transfer coefficient of  $40 \text{ W/m}^2\cdot\text{K}$ . Determine the increase in heat transfer from the tube per meter of its length as a result of adding fins. *Answer: 2636 W*

FIGURE P3–128

**3–129** A 0.3-cm-thick, 12-cm-high, and 18-cm-long circuit board houses 80 closely spaced logic chips on one side, each dissipating 0.04 W. The board is impregnated with copper fillings and has an effective thermal conductivity of  $30 \text{ W/m}\cdot\text{K}$ . All the heat generated in the chips is conducted across the circuit board and is dissipated from the back side of the board to a medium at  $40^\circ\text{C}$ , with a heat transfer coefficient of  $40 \text{ W/m}^2\cdot\text{K}$ . (a) Determine the temperatures on the two sides of the circuit board. (b) Now a 0.2-cm-thick, 12-cm-high, and 18-cm-long aluminum plate ( $k = 237 \text{ W/m}\cdot\text{K}$ ) with 864 2-cm-long aluminum pin fins of diameter 0.25 cm is attached to the back side of the circuit board with a 0.02-cm-thick epoxy adhesive

( $k = 1.8 \text{ W/m}\cdot\text{K}$ ). Determine the new temperatures on the two sides of the circuit board.

**3–130** A hot surface at  $100^\circ\text{C}$  is to be cooled by attaching 3-cm-long, 0.25-cm-diameter aluminum pin fins ( $k = 237 \text{ W/m}\cdot\text{K}$ ) to it, with a center-to-center distance of 0.6 cm. The temperature of the surrounding medium is  $30^\circ\text{C}$ , and the heat transfer coefficient on the surfaces is  $35 \text{ W/m}^2\cdot\text{K}$ . Determine the rate of heat transfer from the surface for a  $1\text{-m} \times 1\text{-m}$  section of the plate. Also determine the overall effectiveness of the fins.

FIGURE P3–130

**3–131** Reconsider Prob. 3–130. Using EES (or other) software, investigate the effect of the center-to-center distance of the fins on the rate of heat transfer from the surface and the overall effectiveness of the fins. Let the center-to-center distance vary from 0.4 cm to 2.0 cm. Plot the rate of heat transfer and the overall effectiveness as a function of the center-to-center distance, and discuss the results.

**3–132** Circular cooling fins of diameter  $D = 1 \text{ mm}$  and length  $L = 25.4 \text{ mm}$ , made of copper ( $k = 400 \text{ W/m}\cdot\text{K}$ ), are used to enhance heat transfer from a surface that is maintained at temperature  $T_{s1} = 132^\circ\text{C}$ . Each rod has one end attached to this surface ( $x = 0$ ), while the opposite end ( $x = L$ ) is joined to a second surface, which is maintained at  $T_{s2} = 0^\circ\text{C}$ . The air flowing between the surfaces and the rods is also at  $T_\infty = 0^\circ\text{C}$ , and the convection coefficient is  $h = 100 \text{ W/m}^2\cdot\text{K}$ .

- (a) Express the function  $\theta(x) = T(x) - T_\infty$  along a fin, and calculate the temperature at  $x = L/2$ .

FIGURE P3–132

- (b) Determine the rate of heat transferred from the hot surface through each fin and the fin effectiveness. Is the use of fins justified? Why?
- (c) What is the total rate of heat transfer from a 10-cm by 10-cm section of the wall, which has 625 uniformly distributed fins? Assume the same convection coefficient for the fin and for the unfinned wall surface.

**3-133** A 40-W power transistor is to be cooled by attaching it to one of the commercially available heat sinks shown in Table 3-6. Select a heat sink that will allow the case temperature of the transistor not to exceed 90°C in the ambient air at 20°C.

FIGURE P3-133

**3-134** A 25-W power transistor is to be cooled by attaching it to one of the commercially available heat sinks shown in Table 3-6. Select a heat sink that will allow the case temperature of the transistor not to exceed 55°C in the ambient air at 18°C.

### Bioheat Transfer Equation

**3-135** The human body is adaptable to the extreme climatic conditions and keep the body core and skin temperature within the comfort zone by regulating the metabolic heat generation rate. For example, in extreme cold conditions, human body will maintain the body temperature by increasing metabolic heat generation rate while in very hot environment, human body will sweat and release heat generated within the body. To understand this effect of ambient conditions on human body repeat Example 3-14 in the text and consider a case, where climatic conditions change from -20°C and 20°C. For this change in ambient air temperature calculate the metabolic heat generation rate required within the different human body types with the skin/fat thickness of 0.0075, 0.005 and 0.0025 m so as to maintain the skin temperature at 34°C. Assume that inspite of the change in ambient air temperature the perspiration rate remains constant at 0.0005 s<sup>-1</sup>. Plot a graph of metabolic heat generation rate against the ambient temperature with a temperature increment of 5°C.

**3-136** Consider the conditions of Example 3-14 in the text for two different environments of air and water with convective heat transfer coefficient of 2 W/m<sup>2</sup>·K and 20 W/m<sup>2</sup>·K, respectively. The ambient ( $T_{\infty}$ ) and surrounding temperature ( $T_{\text{surr}}$ ) for both air and water may be assumed to be 15°C. What

would be the metabolic heat generation rate required to maintain the skin temperature at 34°C?

**3-137** Consider the conditions of Example 3-14 in the text except that the ambient air is at a temperature of 30°C. A person with skin/fat layer thickness of 0.003 m is doing vigorous exercise which raises the metabolic heat generation rate from 700 to 7000 W/m<sup>3</sup> over a period of time. Calculate the perspiration rate required in lit/s so as to maintain the skin temperature at 34°C. Use the perspiration properties to be the same as that of liquid water at the average surface skin temperature of 35.5°C.

**3-138** We are interested in steady state heat transfer analysis from a human forearm subjected to certain environmental conditions. For this purpose consider the forearm to be made up of muscle with thickness  $r_m$  with a skin/fat layer of thickness  $t_{sf}$  over it, as shown in the Figure P3-138. For simplicity approximate the forearm as a one-dimensional cylinder and ignore the presence of bones. The metabolic heat generation rate ( $\dot{e}_m$ ) and perfusion rate ( $\dot{p}$ ) are both constant throughout the muscle. The blood density and specific heat are  $\rho_b$  and  $c_b$ , respectively. The core body temperate ( $T_c$ ) and the arterial blood temperature ( $T_a$ ) are both assumed to be the same and constant. The muscle and the skin/fat layer thermal conductivities are  $k_m$  and  $k_{sf}$ , respectively. The skin has an emissivity of  $\varepsilon$  and the forearm is subjected to an air environment with a temperature of  $T_{\infty}$ , a convection heat transfer coefficient of  $h_{\text{conv}}$ , and a radiation heat transfer coefficient of  $h_{\text{rad}}$ . Assuming blood properties and thermal conductivities are all constant, (a) write the bioheat transfer equation in radial coordinates. The boundary conditions for the forearm are specified constant temperature at the outer surface of the muscle ( $T_i$ ) and temperature symmetry at the centerline of the forearm. (b) Solve the differential equation and apply the boundary conditions to develop an expression for the temperature distribution in the forearm. (c) Determine the temperature at the outer surface of the muscle ( $T_i$ ) and the maximum temperature in the forearm ( $T_{\max}$ ) for the following conditions:

$$\begin{aligned} r_m &= 0.05 \text{ m}, t_{sf} = 0.003 \text{ m}, \dot{e}_m = 700 \text{ W/m}^3, \dot{p} = 0.0005 \text{ l/s}, \\ T_a &= 37^\circ\text{C}, T_{\infty} = T_{\text{surr}} = 24^\circ\text{C}, \varepsilon = 0.95, \\ \rho_b &= 1000 \text{ kg/m}^3, c_b = 3600 \text{ J/kg·K}, k_m = 0.5 \text{ W/m·K}, \\ k_{sf} &= 0.3 \text{ W/m·K}, h_{\text{conv}} = 2 \text{ W/m}^2\cdot\text{K}, h_{\text{rad}} = 5.9 \text{ W/m}^2\cdot\text{K} \end{aligned}$$

FIGURE P3-138

### Heat Transfer in Common Configurations

**3-139C** What is a conduction shape factor? How is it related to the thermal resistance?

**3-140C** What is the value of conduction shape factors in engineering?

**3-141** A 20-m-long and 8-cm-diameter hot-water pipe of a district heating system is buried in the soil 80 cm below the ground surface. The outer surface temperature of the pipe is 60°C. Taking the surface temperature of the earth to be 5°C and the thermal conductivity of the soil at that location to be 0.9 W/m·K, determine the rate of heat loss from the pipe.

FIGURE P3-141

**3-142** A thin-walled cylindrical container is placed horizontally on a snow covered ground. The container is 1.5 m long and has a diameter of 10 cm. The container contains chemicals undergoing exothermic reaction and generating heat at 900 W/m<sup>3</sup>. After a severe winter storm, the container is covered with approximately 30 cm of fresh snow. At the surface, the snow has a temperature of -5°C. Determine the surface temperature of the container. Discuss whether or not the snow around the container will begin to melt.

**3-143** Hot water at an average temperature of 53°C and an average velocity of 0.4 m/s is flowing through a 5-m section of a thin-walled hot-water pipe that has an outer diameter of 2.5 cm. The pipe passes through the center of a 14-cm-thick wall filled with fiberglass insulation ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ). If the surfaces of the wall are at 18°C, determine (a) the rate of heat transfer from the pipe to the air in the rooms and (b) the temperature drop of the hot water as it flows through this 5-m-long section of the wall. *Answers: 19.6 W, 0.024°C*

FIGURE P3-143

**3-144** Hot- and cold-water pipes 8 m long run parallel to each other in a thick concrete layer. The diameters of both

pipes are 5 cm, and the distance between the centerlines of the pipes is 40 cm. The surface temperatures of the hot and cold pipes are 60°C and 15°C, respectively. Taking the thermal conductivity of the concrete to be  $k = 0.75 \text{ W/m}\cdot\text{K}$ , determine the rate of heat transfer between the pipes. *Answer: 306 W*

**3-145** Reconsider Prob. 3-144. Using EES (or other) software, plot the rate of heat transfer between the pipes as a function of the distance between the centerlines of the pipes in the range of 10 cm to 1.0 m. Discuss the results.

**3-146E** A row of 3-ft-long and 1-in-diameter used uranium fuel rods that are still radioactive are buried in the ground parallel to each other with a center-to-center distance of 8 in at a depth of 15 ft from the ground surface at a location where the thermal conductivity of the soil is 0.6 Btu/h·ft·°F. If the surface temperature of the rods and the ground are 350°F and 60°F, respectively, determine the rate of heat transfer from the fuel rods to the atmosphere through the soil.

FIGURE P3-146E

**3-147** Hot water at an average temperature of 80°C and an average velocity of 1.5 m/s is flowing through a 25-m section of a pipe that has an outer diameter of 5 cm. The pipe extends 2 m in the ambient air above the ground, dips into the ground ( $k = 1.5 \text{ W/m}\cdot\text{K}$ ) vertically for 3 m, and continues horizontally at this depth for 20 m more before it enters the next building. The first section of the pipe is exposed to the ambient air at 8°C, with a heat transfer coefficient of 22 W/m<sup>2</sup>·K. If the surface of the ground is covered with snow at 0°C, determine (a) the total rate of heat loss from the hot water and (b) the temperature drop of the hot water as it flows through this 25-m-long section of the pipe.

FIGURE P3-147

**3-148** Hot water at an average temperature of 85°C passes through a row of eight parallel pipes that are 4 m long and

have an outer diameter of 3 cm, located vertically in the middle of a concrete wall ( $k = 0.75 \text{ W/m}\cdot\text{K}$ ) that is 4 m high, 8 m long, and 15 cm thick. If the surfaces of the concrete walls are exposed to a medium at  $32^\circ\text{C}$ , with a heat transfer coefficient of  $12 \text{ W/m}^2\cdot\text{K}$ , determine the rate of heat loss from the hot water and the surface temperature of the wall.

**3-149** Two flow passages with different cross-sectional shapes, one circular another square, are each centered in a square solid bar of the same dimension and thermal conductivity. Both configurations have the same length,  $T_1$ , and  $T_2$ . Determine which configuration has the higher rate of heat transfer through the square solid bar for (a)  $a = 1.2b$  and (b)  $a = 2b$ .

FIGURE P3-149

**3-150** Consider a tube for transporting steam that is not centered properly in a cylindrical insulation material ( $k = 0.73 \text{ W/m}\cdot\text{K}$ ). The tube diameter is  $D_1 = 20 \text{ cm}$  and the insulation diameter is  $D_2 = 40 \text{ cm}$ . The distance between the center of the tube and the center of the insulation is  $z = 5 \text{ mm}$ . If the surface of the tube maintains a temperature of  $100^\circ\text{C}$  and the outer surface temperature of the insulation is constant at  $30^\circ\text{C}$ , determine the rate of heat transfer per unit length of the tube through the insulation.

FIGURE P3-150

**3-151** Consider two tubes of the same diameter ( $D_1 = 20 \text{ cm}$ ), length, and surface temperature ( $T_1$ ). One tube is properly centered in a cylindrical insulation of  $D_2 = 40 \text{ cm}$ ; the other tube is placed in eccentric with the same diameter cylindrical insulation, where the distance between the center of the tube and the center of the insulation is  $z = 5 \text{ mm}$ . If both configurations have the same outer surface temperature  $T_2$ , determine which configuration has the higher rate of heat transfer through the insulation.

FIGURE P3-151

**3-152** Consider a 25-m-long thick-walled concrete duct ( $k = 0.75 \text{ W/m}\cdot\text{K}$ ) of square cross section. The outer dimensions of the duct are  $20 \text{ cm} \times 20 \text{ cm}$ , and the thickness of the duct wall is 2 cm. If the inner and outer surfaces of the duct are at  $100^\circ\text{C}$  and  $30^\circ\text{C}$ , respectively, determine the rate of heat transfer through the walls of the duct. *Answer: 47.1 kW*

FIGURE P3-152

**3-153** Consider a house with a flat roof whose outer dimensions are  $12 \text{ m} \times 12 \text{ m}$ . The outer walls of the house are 6 m high. The walls and the roof of the house are made of 20-cm-thick concrete ( $k = 0.75 \text{ W/m}\cdot\text{K}$ ). The temperatures of the inner and outer surfaces of the house are  $15^\circ\text{C}$  and  $3^\circ\text{C}$ , respectively. Accounting for the effects of the edges of adjoining surfaces, determine the rate of heat loss from the house through its walls and the roof. What is the error involved in ignoring the effects of the edges and corners and treating the roof as a  $12 \text{ m} \times 12 \text{ m}$  surface and the walls as  $6 \text{ m} \times 12 \text{ m}$  surfaces for simplicity?

**3-154** A 3-m-diameter spherical tank containing some radioactive material is buried in the ground ( $k = 1.4 \text{ W/m}\cdot\text{K}$ ). The distance between the top surface of the tank and the ground surface is 4 m. If the surface temperatures of the tank and the ground are  $140^\circ\text{C}$  and  $15^\circ\text{C}$ , respectively, determine the rate of heat transfer from the tank.

**3-155** Radioactive material, stored in a spherical vessel of diameter  $D = 3.5 \text{ m}$ , is buried underground at a depth of 10 m. The radioactive material inside the vessel releases heat at a rate of  $1000 \text{ W/m}^3$ . The surface temperature of the vessel is constant at  $480^\circ\text{C}$  and the thermal conductivity of the ground is  $2 \text{ W/m}\cdot\text{K}$ . When it snows in the winter, will the area directly above the spherical vessel be covered with snow?

### Special Topics:

#### Heat Transfer through the Walls and Roofs

**3–156C** What is the  $R$ -value of a wall? How does it differ from the unit thermal resistance of the wall? How is it related to the  $U$ -factor?

**3–157C** What is effective emissivity for a plane-parallel air space? How is it determined? How is radiation heat transfer through the air space determined when the effective emissivity is known?

**3–158C** The unit thermal resistances ( $R$ -values) of both 40-mm and 90-mm vertical air spaces are given in Table 3–9 to be  $0.22 \text{ m}^2\text{·C/W}$ , which implies that more than doubling the thickness of air space in a wall has no effect on heat transfer through the wall. Do you think this is a typing error? Explain.

**3–159C** What is a radiant barrier? What kind of materials are suitable for use as radiant barriers? Is it worthwhile to use radiant barriers in the attics of homes?

**3–160C** Consider a house whose attic space is ventilated effectively so that the air temperature in the attic is the same as the ambient air temperature at all times. Will the roof still have any effect on heat transfer through the ceiling? Explain.

**3–161** Determine the summer  $R$ -value and the  $U$ -factor of a wood frame wall that is built around  $38\text{-mm} \times 140\text{-mm}$  wood studs with a center-to-center distance of 400 mm. The 140-mm-wide cavity between the studs is filled with mineral fiber batt insulation. The inside is finished with 13-mm gypsum wallboard and the outside with 13-mm wood fiberboard and 13-mm  $\times$  200-mm wood bevel lapped siding. The insulated cavity constitutes 80 percent of the heat transmission area, while the studs, headers, plates, and sills constitute 20 percent.

*Answers:  $3.213 \text{ m}^2\text{·K/W}$ ,  $0.311 \text{ W/m}^2\text{·K}$*

**3–162** The 13-mm-thick wood fiberboard sheathing of the wood stud wall in Prob. 3–161 is replaced by a 25-mm-thick rigid foam insulation. Determine the percent increase in the  $R$ -value of the wall as a result.

FIGURE P3–162

**3–163** The overall heat transfer coefficient (the  $U$ -value) of a wall under winter design conditions is  $U = 2.25 \text{ W/m}^2\text{·K}$ . Now a layer of 100-mm face brick is added to the outside, leaving a 20-mm air space between the wall and the bricks. Determine the new  $U$ -value of the wall. Also, determine the rate of heat transfer through a 3-m-high, 7-m-long section of the wall after modification when the indoor and outdoor temperatures are  $22^\circ\text{C}$  and  $-25^\circ\text{C}$ , respectively.

FIGURE P3–163

**3–164** Consider a flat ceiling that is built around  $38\text{-mm} \times 90\text{-mm}$  wood studs with a center-to-center distance of 400 mm. The lower part of the ceiling is finished with 13-mm gypsum wallboard, while the upper part consists of a wood subfloor ( $R = 0.166 \text{ m}^2\text{·C/W}$ ), a 13-mm plywood, a layer of felt ( $R = 0.011 \text{ m}^2\text{·C/W}$ ), and linoleum ( $R = 0.009 \text{ m}^2\text{·C/W}$ ). Both sides of the ceiling are exposed to still air. The air space constitutes 82 percent of the heat transmission area, while the studs and headers constitute 18 percent. Determine the winter  $R$ -value and the  $U$ -factor of the ceiling assuming the 90-mm-wide air space between the studs (a) does not have any reflective surface, (b) has a reflective surface with  $\varepsilon = 0.05$  on one side, and (c) has reflective surfaces with  $\varepsilon = 0.05$  on both sides. Assume a mean temperature of  $10^\circ\text{C}$  and a temperature difference of  $5.6^\circ\text{C}$  for the air space.

FIGURE P3–164

**3–165** Determine the winter  $R$ -value and the  $U$ -factor of a masonry cavity wall that consists of 100-mm common bricks, a 90-mm air space, 100-mm concrete blocks made of lightweight aggregate, 20-mm air space, and 13-mm gypsum wallboard separated from the concrete block by 20-mm-thick (1-in  $\times$  3-in nominal) vertical furring whose center-to-center distance is 400 mm. Neither side of the two air spaces is coated with any reflective films. When determining the  $R$ -value of the air spaces, the temperature difference across them can be taken to be  $16.7^{\circ}\text{C}$  with a mean air temperature of  $10^{\circ}\text{C}$ . The air space constitutes 84 percent of the heat transmission area, while the vertical furring and similar structures constitute 16 percent.

*Answers:*  $1.02 \text{ m}^2\cdot^{\circ}\text{C}/\text{W}$ ,  $0.978 \text{ W}/\text{m}^2\cdot\text{K}$

**FIGURE P3–165**

**3–166** Repeat Prob. 3–165 assuming one side of both air spaces is coated with a reflective film of  $\varepsilon = 0.05$ .

**3–167** Determine the winter  $R$ -value and the  $U$ -factor of a masonry wall that consists of the following layers: 100-mm face bricks, 100-mm common bricks, 25-mm urethane rigid foam insulation, and 13-mm gypsum wallboard.

*Answers:*  $1.404 \text{ m}^2\cdot^{\circ}\text{C}/\text{W}$ ,  $0.712 \text{ W}/\text{m}^2\cdot\text{K}$

**3–168** The overall heat transfer coefficient (the  $U$ -value) of a wall under winter design conditions is  $U = 1.40 \text{ W}/\text{m}^2\cdot\text{K}$ . Determine the  $U$ -value of the wall under summer design conditions.

**3–169E** Determine the winter  $R$ -value and the  $U$ -factor of a masonry cavity wall that is built around 4-in-thick concrete blocks made of lightweight aggregate. The outside is finished with 4-in face brick with  $\frac{1}{2}$ -in cement mortar between the bricks and concrete blocks. The inside finish consists of  $\frac{1}{2}$ -in gypsum wallboard separated from the concrete block by  $\frac{3}{4}$ -in-thick (1-in by 3-in nominal) vertical furring whose center-to-center distance is 16 in. Neither side of the  $\frac{3}{4}$ -in-thick air space between the concrete block and the gypsum board

is coated with any reflective film. When determining the  $R$ -value of the air space, the temperature difference across it can be taken to be  $30^{\circ}\text{F}$  with a mean air temperature of  $50^{\circ}\text{F}$ . The air space constitutes 80 percent of the heat transmission area, while the vertical furring and similar structures constitute 20 percent.

**FIGURE P3–169E**

**3–170** Determine the summer and winter  $R$ -values, in  $\text{m}^2\cdot^{\circ}\text{C}/\text{W}$ , of a masonry wall that consists of 100-mm face bricks, 13-mm of cement mortar, 100-mm lightweight concrete block, 40-mm air space, and 20-mm plasterboard.

*Answers:*  $0.809$  and  $0.795 \text{ m}^2\cdot^{\circ}\text{C}/\text{W}$

**3–171E** The overall heat transfer coefficient of a wall is determined to be  $U = 0.075 \text{ Btu}/\text{h}\cdot\text{ft}^2\cdot\text{F}$  under the conditions of still air inside and winds of 7.5 mph outside. What will the  $U$ -factor be when the wind velocity outside is doubled? *Answer:*  $0.0755 \text{ Btu}/\text{h}\cdot\text{ft}^2\cdot\text{F}$

**3–172** Two homes are identical, except that the walls of one house consist of 200-mm lightweight concrete blocks, 20-mm air space, and 20-mm plasterboard, while the walls of the other house involve the standard  $R=2.4 \text{ m}^2\cdot^{\circ}\text{C}/\text{W}$  frame wall construction. Which house do you think is more energy efficient?

**3–173** Determine the  $R$ -value of a ceiling that consists of a layer of 19-mm acoustical tiles whose top surface is covered with a highly reflective aluminum foil for winter conditions. Assume still air below and above the tiles.

**FIGURE P3–173**

### Review Problems

**3–174** Consider two identical people each generating 60 W of metabolic heat steadily while doing sedentary work, and dissipating it by convection and perspiration. The first person is wearing clothes made of 1-mm-thick leather ( $k = 0.159 \text{ W/m}\cdot\text{K}$ ) that covers half of the body while the second one is wearing clothes made of 1-mm-thick synthetic fabric ( $k = 0.13 \text{ W/m}\cdot\text{K}$ ) that covers the body completely. The ambient air is at 30°C, the heat transfer coefficient at the outer surface is 15 W/m<sup>2</sup>·K, and the inner surface temperature of the clothes can be taken to be 32°C. Treating the body of each person as a 25-cm-diameter, 1.7-m-long cylinder, determine the fractions of heat lost from each person by perspiration.

**3–175** Cold conditioned air at 12°C is flowing inside a 1.5-cm-thick square aluminum ( $k = 237 \text{ W/m}\cdot\text{K}$ ) duct of inner cross section 22 cm × 22 cm at a mass flow rate of 0.8 kg/s. The duct is exposed to air at 33°C with a combined convection-radiation heat transfer coefficient of 13 W/m<sup>2</sup>·K. The convection heat transfer coefficient at the inner surface is 75 W/m<sup>2</sup>·K. If the air temperature in the duct should not increase by more than 1°C determine the maximum length of the duct.

**3–176** Hot water is flowing at an average velocity of 1.5 m/s through a cast iron pipe ( $k = 52 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are 3 cm and 3.5 cm, respectively. The pipe passes through a 15-m-long section of a basement whose temperature is 15°C. If the temperature of the water drops from 70°C to 67°C as it passes through the basement and the heat transfer coefficient on the inner surface of the pipe is 400 W/m<sup>2</sup>·K, determine the combined convection and radiation heat transfer coefficient at the outer surface of the pipe. *Answer: 272.5 W/m<sup>2</sup>·K*

**3–177** The plumbing system of a house involves a 0.5-m section of a plastic pipe ( $k = 0.16 \text{ W/m}\cdot\text{K}$ ) of inner diameter 2 cm and outer diameter 2.4 cm exposed to the ambient air. During a cold and windy night, the ambient air temperature remains at about –5°C for a period of 14 h. The combined convection and radiation heat transfer coefficient on the outer surface of

**FIGURE P3–177**

the pipe is estimated to be 40 W/m<sup>2</sup>·K, and the heat of fusion of water is 333.7 kJ/kg. Assuming the pipe to contain stationary water initially at 0°C, determine if the water in that section of the pipe will completely freeze that night.

**3–178** A cylindrical nuclear fuel rod of 15 mm in diameter is encased in a concentric hollow ceramic cylinder with inner

diameter of 35 mm and outer diameter of 110 mm. This created an air gap between the fuel rod and the hollow ceramic cylinder with a convection heat transfer coefficient of 10 W/m<sup>2</sup>·K. The hollow ceramic cylinder has a thermal conductivity of 0.07 W/m·K and its outer surface maintains a constant temperature of 30°C. If the fuel rod generates heat at a rate of 1 MW/m<sup>3</sup>, determine the temperature at the surface of the fuel rod. *Answer: 1026°C*

**FIGURE P3–178**

**3–179** Steam at 235°C is flowing inside a steel pipe ( $k = 61 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are 10 cm and 12 cm, respectively, in an environment at 20°C. The heat transfer coefficients inside and outside the pipe are 105 W/m<sup>2</sup>·K and 14 W/m<sup>2</sup>·K, respectively. Determine (a) the thickness of the insulation ( $k = 0.038 \text{ W/m}\cdot\text{K}$ ) needed to reduce the heat loss by 95 percent and (b) the thickness of the insulation needed to reduce the exposed surface temperature of insulated pipe to 40°C for safety reasons.

**3–180** A spherical vessel, 3.0 m in diameter (and negligible wall thickness), is used for storing a fluid at a temperature of 0°C. The vessel is covered with a 5.0-cm-thick layer of an insulation ( $k = 0.20 \text{ W/m}\cdot\text{K}$ ). The surrounding air is at 22°C. The inside and outside heat transfer coefficients are 40 and 10 W/m<sup>2</sup>·K, respectively. Calculate (a) all thermal resistances, in K/W, (b) the steady rate of heat transfer, and (c) the temperature difference across the insulation layer.

**3–181** One wall of a refrigerated warehouse is 10.0-m-high and 5.0-m-wide. The wall is made of three layers: 1.0-cm-thick aluminum ( $k = 200 \text{ W/m}\cdot\text{K}$ ), 8.0-cm-thick fibreglass ( $k = 0.038 \text{ W/m}\cdot\text{K}$ ), and 3.0-cm thick gypsum board ( $k = 0.48 \text{ W/m}\cdot\text{K}$ ). The warehouse inside and outside temperatures are –10°C and 20°C, respectively, and the average value of both inside and outside heat transfer coefficients is 40 W/m<sup>2</sup>·K.

- (a) Calculate the rate of heat transfer across the warehouse wall in steady operation.
- (b) Suppose that 400 metal bolts ( $k = 43 \text{ W/m}\cdot\text{K}$ ), each 2.0 cm in diameter and 12.0 cm long, are used to fasten (i.e., hold together) the three wall layers. Calculate the rate of heat transfer for the “bolted” wall.

(c) What is the percent change in the rate of heat transfer across the wall due to metal bolts?

**3–182** A 4-m-high and 6-m-long wall is constructed of two large 2-cm-thick steel plates ( $k = 15 \text{ W/m}\cdot\text{K}$ ) separated by 1-cm-thick and 20-cm wide steel bars placed 99 cm apart. The remaining space between the steel plates is filled with fiberglass insulation ( $k = 0.035 \text{ W/m}\cdot\text{K}$ ). If the temperature difference between the inner and the outer surfaces of the walls is  $22^\circ\text{C}$ , determine the rate of heat transfer through the wall. Can we ignore the steel bars between the plates in heat transfer analysis since they occupy only 1 percent of the heat transfer surface area?

FIGURE P3–182

**3–183** A typical section of a building wall is shown in Fig. P3–183. This section extends in and out of the page and is repeated in the vertical direction. The wall support members are made of steel ( $k = 50 \text{ W/m}\cdot\text{K}$ ). The support members are  $8 \text{ cm} (t_{23}) \times 0.5 \text{ cm} (L_B)$ . The remainder of the inner wall space is filled with insulation ( $k = 0.03 \text{ W/m}\cdot\text{K}$ ) and measures  $8 \text{ cm} (t_{23}) \times 60 \text{ cm} (L_B)$ . The inner wall is made of gypsum board ( $k = 0.5 \text{ W/m}\cdot\text{K}$ ) that is 1 cm thick ( $t_{12}$ ) and the outer wall is made of brick ( $k = 1.0 \text{ W/m}\cdot\text{K}$ ) that is 10 cm thick ( $t_{34}$ ). What is the temperature on the interior brick surface, 3, when  $T_1 = 20^\circ\text{C}$  and  $T_4 = 35^\circ\text{C}$ ?

FIGURE P3–183

**3–184** A 10-cm-long bar with a square cross-section, as shown in Fig. P3–184, consists of a 1-cm-thick copper layer ( $k = 400 \text{ W/m}\cdot\text{K}$ ) and a 1-cm-thick epoxy composite layer ( $k = 0.4 \text{ W/m}\cdot\text{K}$ ). Calculate the rate of heat transfer under a thermal driving force of  $50^\circ\text{C}$ , when the direction of steady one-dimensional heat transfer is (a) from front to back (i.e., along its length), (b) from left to right, and (c) from top to bottom.

FIGURE P3–184

**3–185** Circular fins of uniform cross section, with diameter of 10 mm and length of 50 mm, are attached to a wall with surface temperature of  $350^\circ\text{C}$ . The fins are made of material with thermal conductivity of  $240 \text{ W/m}\cdot\text{K}$ , and they are exposed to an ambient air condition of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $250 \text{ W/m}^2\cdot\text{K}$ . Determine the heat transfer rate and plot the temperature variation of a single fin for the following boundary conditions:

- Infinitely long fin
- Adiabatic fin tip
- Fin with tip temperature of  $250^\circ\text{C}$
- Convection from the fin tip

FIGURE P3–185

**3–186** A total of 10 rectangular aluminum fins ( $k = 203 \text{ W/m}\cdot\text{K}$ ) are placed on the outside flat surface of an electronic device. Each fin is 100 mm wide, 20 mm high and 4 mm thick. The fins are located parallel to each other at a center-to-center distance of 8 mm. The temperature at the outside surface of the electronic device is  $60^\circ\text{C}$ . The air is at  $20^\circ\text{C}$ , and the heat transfer coefficient is  $100 \text{ W/m}^2\cdot\text{K}$ . Determine (a) the rate of heat loss from the electronic device to the surrounding air and (b) the fin effectiveness.

**3–187** A plane wall with surface temperature of  $300^\circ\text{C}$  is attached with straight aluminum triangular fins ( $k = 236 \text{ W/m}\cdot\text{K}$ ). The fins are exposed to an ambient air condition

of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $25 \text{ W/m}^2\cdot\text{K}$ . Each fin has a length of 55 mm, a base of 4 mm thick and a width of 110 mm. Using Table 3–4, determine the efficiency, heat transfer rate, and effectiveness of each fin.

**FIGURE P3–187**

**3–188** A plane wall surface at  $200^\circ\text{C}$  is to be cooled with aluminum pin fins of parabolic profile with blunt tips. Each fin has a length of 25 mm and a base diameter of 4 mm. The fins are exposed to an ambient air condition of  $25^\circ\text{C}$  and the heat transfer coefficient is  $45 \text{ W/m}^2\cdot\text{K}$ . If the thermal conductivity of the fins is  $230 \text{ W/m}\cdot\text{K}$ , determine the heat transfer rate from a single fin and the increase in the rate of heat transfer per  $\text{m}^2$  surface area as a result of attaching fins. Assume there are 100 fins per  $\text{m}^2$  surface area.

**3–189** Steam in a heating system flows through tubes whose outer diameter is 3 cm and whose walls are maintained at a temperature of  $120^\circ\text{C}$ . Circular aluminum alloy fins ( $k = 180 \text{ W/m}\cdot\text{K}$ ) of outer diameter 6 cm and constant thickness  $t = 2 \text{ mm}$  are attached to the tube, as shown in Fig. P3–189. The space between the fins is 3 mm, and thus there are 200 fins per meter length of the tube. Heat is transferred to the surrounding air at  $25^\circ\text{C}$ , with a combined heat transfer coefficient of  $60 \text{ W/m}^2\cdot\text{K}$ . Determine the increase in heat transfer from the tube per meter of its length as a result of adding fins.

**FIGURE P3–189**

**3–190** A 0.2-cm-thick, 10-cm-high, and 15-cm-long circuit board houses electronic components on one side that dissipate a total of 15 W of heat uniformly. The board is impregnated with conducting metal fillings and has an effective thermal conductivity of  $12 \text{ W/m}\cdot\text{K}$ . All the heat generated in the components is conducted across the circuit board and is dissipated

from the back side of the board to a medium at  $37^\circ\text{C}$ , with a heat transfer coefficient of  $45 \text{ W/m}^2\cdot\text{K}$ . (a) Determine the surface temperatures on the two sides of the circuit board. (b) Now a 0.1-cm-thick, 10-cm-high, and 15-cm-long aluminum plate ( $k = 237 \text{ W/m}\cdot\text{K}$ ) with 20 0.2-cm-thick, 2-cm-long, and 15-cm-wide aluminum fins of rectangular profile are attached to the back side of the circuit board with a 0.03-cm-thick epoxy adhesive ( $k = 1.8 \text{ W/m}\cdot\text{K}$ ). Determine the new temperatures on the two sides of the circuit board.

**FIGURE P3–190**

**3–191** In a manufacturing plant, 100 mm by 40 mm thin rectangular electronic devices are assembled in mass quantity. The top surface of the electronic device is made of aluminum and is attached with a HS 5030 aluminum heat sink positioned horizontally. The electronic device dissipates 45 W of heat through the heat sink. Both aluminum surfaces have a roughness of about  $10 \mu\text{m}$  and an average interface pressure of 1 atm. To prevent the electronic device from overheating, the top surface temperature should be kept below  $85^\circ\text{C}$  in an ambient surrounding of  $30^\circ\text{C}$ . Your task as a product engineer is to ensure that the heat sink attached on the device's top surface is capable to keep the device from overheating. Determine whether or not the top surface temperature of the electronic device, with a HS 5030 heat sink attached on it, is higher than  $85^\circ\text{C}$ . If so, what action can be taken to reduce the surface temperature to below  $85^\circ\text{C}$ ? Since your company has a vast quantity of the HS 5030 heat sinks in the inventory, replacing the heat sinks with more effective ones is too costly and is not a viable solution.

**3–192** A row of 10 parallel pipes that are 5 m long and have an outer diameter of 6 cm are used to transport steam at  $145^\circ\text{C}$  through the concrete floor ( $k = 0.75 \text{ W/m}\cdot\text{K}$ ) of a 10-m  $\times$  5-m room that is maintained at  $20^\circ\text{C}$ . The combined convection and radiation heat transfer coefficient at the floor is  $12 \text{ W/m}^2\cdot\text{K}$ . If the surface temperature of the concrete floor is not to exceed

35°C, determine how deep the steam pipes should be buried below the surface of the concrete floor.

**FIGURE P3–192**

**3–193** A 0.6-m-diameter, 1.9-m-long cylindrical tank containing liquefied natural gas (LNG) at  $-160^{\circ}\text{C}$  is placed at the center of a 1.9-m-long 1.4-m  $\times$  1.4-m square solid bar made of an insulating material with  $k = 0.0002 \text{ W/m}\cdot\text{K}$ . If the outer surface temperature of the bar is 12°C, determine the rate of heat transfer to the tank. Also, determine the LNG temperature after one month. Take the density and the specific heat of LNG to be  $425 \text{ kg/m}^3$  and  $3.475 \text{ kJ/kg}\cdot^{\circ}\text{C}$ , respectively.

**3–194** In a combined heat and power (CHP) generation process, by-product heat is used for domestic or industrial heating purposes. Hot steam is carried from a CHP generation plant by a tube with diameter of 127 mm centered at a square cross-section solid bar made of concrete with thermal conductivity of  $1.7 \text{ W/m}\cdot\text{K}$ . The surface temperature of the tube is constant at  $120^{\circ}\text{C}$ , while the square concrete bar is exposed to air with temperature of  $-5^{\circ}\text{C}$  and convection heat transfer coefficient of  $20 \text{ W/m}^2\cdot\text{K}$ . If the temperature difference between the outer surface of the square concrete bar and the ambient air is to be maintained at  $5^{\circ}\text{C}$ , determine the width of the square concrete bar and the rate of heat loss per meter length.

*Answers:* 1.32 m, 530 W/m

**FIGURE P3–194**

**3–195** A 1.4-m-diameter spherical steel tank filled with iced water at  $0^{\circ}\text{C}$  is buried underground at a location where the thermal conductivity of the soil is  $k = 0.55 \text{ W/m}\cdot\text{K}$ . The distance between the tank center and the ground surface is 2.4 m. For ground surface temperature of  $18^{\circ}\text{C}$ , determine the rate of heat transfer to

the iced water in the tank. What would your answer be if the soil temperature were  $18^{\circ}\text{C}$  and the ground surface were insulated?

**3–196** A thin-walled spherical tank is buried in the ground at a depth of 3 m. The tank has a diameter of 1.5 m, and it contains chemicals undergoing exothermic reaction that provides a uniform heat flux of  $1 \text{ kW/m}^2$  to the tank's inner surface. From soil analysis, the ground has a thermal conductivity of  $1.3 \text{ W/m}\cdot\text{K}$  and a temperature of  $10^{\circ}\text{C}$ . Determine the surface temperature of the tank. Discuss the effect of the ground depth on the surface temperature of the tank.

### Fundamentals of Engineering (FE) Exam Problems

**3–197** Heat is lost at a rate of  $275 \text{ W per m}^2$  area of a 15-cm-thick wall with a thermal conductivity of  $k = 1.1 \text{ W/m}\cdot\text{K}$ . The temperature drop across the wall is

- (a)  $37.5^{\circ}\text{C}$       (b)  $27.5^{\circ}\text{C}$       (c)  $16.0^{\circ}\text{C}$   
 (d)  $8.0^{\circ}\text{C}$       (e)  $4.0^{\circ}\text{C}$

**3–198** Consider a wall that consists of two layers, A and B, with the following values:  $k_A = 0.8 \text{ W/m}\cdot\text{K}$ ,  $L_A = 8 \text{ cm}$ ,  $k_B = 0.2 \text{ W/m}\cdot\text{K}$ ,  $L_B = 5 \text{ cm}$ . If the temperature drop across the wall is  $18^{\circ}\text{C}$ , the rate of heat transfer through the wall per unit area of the wall is

- (a)  $180 \text{ W/m}^2$       (b)  $153 \text{ W/m}^2$       (c)  $89.6 \text{ W/m}^2$   
 (d)  $72 \text{ W/m}^2$       (e)  $51.4 \text{ W/m}^2$

**3–199** Heat is generated steadily in a 3-cm-diameter spherical ball. The ball is exposed to ambient air at  $26^{\circ}\text{C}$  with a heat transfer coefficient of  $7.5 \text{ W/m}^2\cdot\text{K}$ . The ball is to be covered with a material of thermal conductivity  $0.15 \text{ W/m}\cdot\text{K}$ . The thickness of the covering material that will maximize heat generation within the ball while maintaining ball surface temperature constant is

- (a) 0.5 cm      (b) 1.0 cm      (c) 1.5 cm  
 (d) 2.0 cm      (e) 2.5 cm

**3–200** Consider a 1.5-m-high and 2-m-wide triple pane window. The thickness of each glass layer ( $k = 0.80 \text{ W/m}\cdot\text{K}$ ) is 0.5 cm, and the thickness of each air space ( $k = 0.025 \text{ W/m}\cdot\text{K}$ ) is 1 cm. If the inner and outer surface temperatures of the window are  $10^{\circ}\text{C}$  and  $0^{\circ}\text{C}$ , respectively, the rate of heat loss through the window is

- (a) 75 W      (b) 12 W      (c) 46 W  
 (d) 25 W      (e) 37 W

**3–201** Consider two metal plates pressed against each other. Other things being equal, which of the measures below will cause the thermal contact resistance to increase?

- (a) Cleaning the surfaces to make them shinier.  
 (b) Pressing the plates against each other with a greater force.  
 (c) Filling the gap with a conducting fluid.  
 (d) Using softer metals.  
 (e) Coating the contact surfaces with a thin layer of soft metal such as tin.

**3–202** A 10-m-long 5-cm-outer-radius cylindrical steam pipe is covered with 3-cm thick cylindrical insulation with a thermal

conductivity of 0.05 W/m·K. If the rate of heat loss from the pipe is 1000 W, the temperature drop across the insulation is

- (a) 163°C      (b) 600°C      (c) 48°C  
 (d) 79°C      (e) 251°C

**3-203** A 6-m-diameter spherical tank is filled with liquid oxygen ( $\rho = 1141 \text{ kg/m}^3$ ,  $c_p = 1.71 \text{ kJ/kg}\cdot\text{°C}$ ) at  $-184^\circ\text{C}$ . It is observed that the temperature of oxygen increases to  $-183^\circ\text{C}$  in a 144-hour period. The average rate of heat transfer to the tank is

- (a) 249 W      (b) 426 W      (c) 570 W  
 (d) 1640 W      (e) 2207 W

**3-204** A 2.5 m-high, 4-m-wide, and 20-cm-thick wall of a house has a thermal resistance of  $0.0125^\circ\text{C}/\text{W}$ . The thermal conductivity of the wall is

- (a) 0.72 W/m·K      (b) 1.1 W/m·K      (c) 1.6 W/m·K  
 (d) 16 W/m·K      (e) 32 W/m·K

**3-205** Consider two walls, *A* and *B*, with the same surface areas and the same temperature drops across their thicknesses. The ratio of thermal conductivities is  $k_A/k_B = 4$  and the ratio of the wall thicknesses is  $L_A/L_B = 2$ . The ratio of heat transfer rates through the walls  $\dot{Q}_A/\dot{Q}_B$  is

- (a) 0.5      (b) 1      (c) 2      (d) 4      (e) 8

**3-206** A hot plane surface at  $100^\circ\text{C}$  is exposed to air at  $25^\circ\text{C}$  with a combined heat transfer coefficient of  $20 \text{ W/m}^2\cdot\text{K}$ . The heat loss from the surface is to be reduced by half by covering it with sufficient insulation with a thermal conductivity of  $0.10 \text{ W/m}\cdot\text{K}$ . Assuming the heat transfer coefficient to remain constant, the required thickness of insulation is

- (a) 0.1 cm      (b) 0.5 cm      (c) 1.0 cm  
 (d) 2.0 cm      (e) 5 cm

**3-207** A room at  $20^\circ\text{C}$  air temperature is loosing heat to the outdoor air at  $0^\circ\text{C}$  at a rate of 1000 W through a 2.5-m-high and 4-m-long wall. Now the wall is insulated with 2-cm thick insulation with a conductivity of  $0.02 \text{ W/m}\cdot\text{K}$ . Determine the rate of heat loss from the room through this wall after insulation. Assume the heat transfer coefficients on the inner and outer surface of the wall, the room air temperature, and the outdoor air temperature to remain unchanged. Also, disregard radiation.

- (a) 20 W      (b) 561 W      (c) 388 W  
 (d) 167 W      (e) 200 W

**3-208** A 1-cm-diameter, 30-cm-long fin made of aluminum ( $k = 237 \text{ W/m}\cdot\text{K}$ ) is attached to a surface at  $80^\circ\text{C}$ . The surface is exposed to ambient air at  $22^\circ\text{C}$  with a heat transfer coefficient of  $11 \text{ W/m}^2\cdot\text{K}$ . If the fin can be assumed to be very long, the rate of heat transfer from the fin is

- (a) 2.2 W      (b) 3 W      (c) 3.7 W  
 (d) 4 W      (e) 4.7 W

**3-209** A 1-cm-diameter, 30-cm-long fin made of aluminum ( $k = 237 \text{ W/m}\cdot\text{K}$ ) is attached to a surface at  $80^\circ\text{C}$ . The surface is exposed to ambient air at  $22^\circ\text{C}$  with a heat transfer coefficient of  $11 \text{ W/m}^2\cdot\text{K}$ . If the fin can be assumed to be very long, its efficiency is

- (a) 0.60      (b) 0.67      (c) 0.72  
 (d) 0.77      (e) 0.88

**3-210** A hot surface at  $80^\circ\text{C}$  in air at  $20^\circ\text{C}$  is to be cooled by attaching 10-cm-long and 1-cm-diameter cylindrical fins. The combined heat transfer coefficient is  $30 \text{ W/m}^2\cdot\text{K}$ , and heat transfer from the fin tip is negligible. If the fin efficiency is 0.75, the rate of heat loss from 100 fins is

- (a) 325 W      (b) 707 W      (c) 566 W  
 (d) 424 W      (e) 754 W

**3-211** A cylindrical pin fin of diameter 0.6 cm and length of 3 cm with negligible heat loss from the tip has an efficiency of 0.7. The effectiveness of this fin is

- (a) 0.3      (b) 0.7      (c) 2      (d) 8      (e) 14

**3-212** A 3-cm-long, 2-mm  $\times$  2-mm rectangular cross-section aluminum fin ( $k = 237 \text{ W/m}\cdot\text{K}$ ) is attached to a surface. If the fin efficiency is 65 percent, the effectiveness of this single fin is

- (a) 39      (b) 30      (c) 24      (d) 18      (e) 7

**3-213** Two finned surfaces with long fins are identical, except that the convection heat transfer coefficient for the first finned surface is twice that of the second one. What statement below is accurate for the efficiency and effectiveness of the first finned surface relative to the second one?

- (a) Higher efficiency and higher effectiveness  
 (b) Higher efficiency but lower effectiveness  
 (c) Lower efficiency but higher effectiveness  
 (d) Lower efficiency and lower effectiveness  
 (e) Equal efficiency and equal effectiveness

**3-214** A 20-cm-diameter hot sphere at  $120^\circ\text{C}$  is buried in the ground with a thermal conductivity of  $1.2 \text{ W/m}\cdot\text{K}$ . The distance between the center of the sphere and the ground surface is 0.8 m and the ground surface temperature is  $15^\circ\text{C}$ . The rate of heat loss from the sphere is

- (a) 169 W      (b) 20 W      (c) 217 W  
 (d) 312 W      (e) 1.8 W

**3-215** A 25-cm-diameter, 2.4-m-long vertical cylinder containing ice at  $0^\circ\text{C}$  is buried right under the ground. The cylinder is thin-shelled and is made of a high thermal conductivity material. The surface temperature and the thermal conductivity of the ground are  $18^\circ\text{C}$  and  $0.85 \text{ W/m}\cdot\text{K}$  respectively. The rate of heat transfer to the cylinder is

- (a) 37.2 W      (b) 63.2 W      (c) 158 W  
 (d) 480 W      (e) 1210 W

**3-216** Hot water ( $c_p = 4.179 \text{ kJ/kg}\cdot\text{K}$ ) flows through a 200-m-long PVC ( $k = 0.092 \text{ W/m}\cdot\text{K}$ ) pipe whose inner diameter is 2 cm and outer diameter is 2.5 cm at a rate of 1 kg/s, entering at  $40^\circ\text{C}$ . If the entire interior surface of this pipe is maintained at  $35^\circ\text{C}$  and the entire exterior surface at  $20^\circ\text{C}$ , the outlet temperature of water is

- (a)  $39^\circ\text{C}$       (b)  $38^\circ\text{C}$       (c)  $37^\circ\text{C}$   
 (d)  $36^\circ\text{C}$       (e)  $35^\circ\text{C}$

**3–217** The walls of a food storage facility are made of a 2-cm-thick layer of wood ( $k = 0.1 \text{ W/m}\cdot\text{K}$ ) in contact with a 5-cm-thick layer of polyurethane foam ( $k = 0.03 \text{ W/m}\cdot\text{K}$ ). If the temperature of the surface of the wood is  $-10^\circ\text{C}$  and the temperature of the surface of the polyurethane foam is  $20^\circ\text{C}$ , the temperature of the surface where the two layers are in contact is

- (a)  $-7^\circ\text{C}$       (b)  $-2^\circ\text{C}$       (c)  $3^\circ\text{C}$   
 (d)  $8^\circ\text{C}$       (e)  $11^\circ\text{C}$

**3–218** The equivalent thermal resistance for the thermal circuit shown here is

- (a)  $R_{12}R_{01} + R_{23A}R_{23B} + R_{34}$   
 (b)  $R_{12}R_{01} + \left( \frac{R_{23A}R_{23B}}{R_{23A} + R_{23B}} \right) + R_{34}$   
 (c)  $\left( \frac{R_{12}R_{01}}{R_{12} + R_{01}} \right) + \left( \frac{R_{23A}R_{23B}}{R_{23A} + R_{23B}} \right) + \frac{1}{R_{34}}$   
 (d)  $\left( \frac{R_{12}R_{01}}{R_{12} + R_{01}} \right) + \left( \frac{R_{23A}R_{23B}}{R_{23A} + R_{23B}} \right) + R_{34}$

- (e) None of them

**3–219** The  $700 \text{ m}^2$  ceiling of a building has a thermal resistance of  $0.52 \text{ m}^2\cdot\text{K/W}$ . The rate at which heat is lost through this ceiling on a cold winter day when the ambient temperature is  $-10^\circ\text{C}$  and the interior is at  $20^\circ\text{C}$  is

- (a)  $23.1 \text{ kW}$       (b)  $40.4 \text{ kW}$       (c)  $55.6 \text{ kW}$   
 (d)  $68.1 \text{ kW}$       (e)  $88.6 \text{ kW}$

**3–220** A 1-m-inner-diameter liquid-oxygen storage tank at a hospital keeps the liquid oxygen at 90 K. The tank consists of a 0.5-cm-thick aluminum ( $k = 170 \text{ W/m}\cdot\text{K}$ ) shell whose exterior is covered with a 10-cm-thick layer of insulation ( $k = 0.02 \text{ W/m}\cdot\text{K}$ ). The insulation is exposed to the ambient air at  $20^\circ\text{C}$  and the heat transfer coefficient on the exterior side of the insulation is  $5 \text{ W/m}^2\cdot\text{K}$ . The rate at which the liquid oxygen gains heat is

- (a)  $141 \text{ W}$       (b)  $176 \text{ W}$       (c)  $181 \text{ W}$   
 (d)  $201 \text{ W}$       (e)  $221 \text{ W}$

**3–221** A 1-m-inner-diameter liquid-oxygen storage tank at a hospital keeps the liquid oxygen at 90 K. The tank consists of a 0.5-cm-thick aluminum ( $k = 170 \text{ W/m}\cdot\text{K}$ ) shell whose exterior is covered with a 10-cm-thick layer of insulation ( $k = 0.02 \text{ W/m}\cdot\text{K}$ ). The insulation is exposed to the ambient air at  $20^\circ\text{C}$  and the heat transfer coefficient on the exterior side of the insulation is  $5 \text{ W/m}^2\cdot\text{K}$ . The temperature of the exterior surface of the insulation is

- (a)  $13^\circ\text{C}$       (b)  $9^\circ\text{C}$       (c)  $2^\circ\text{C}$   
 (d)  $-3^\circ\text{C}$       (e)  $-12^\circ\text{C}$

**3–222** The fin efficiency is defined as the ratio of the actual heat transfer from the fin to

- (a) The heat transfer from the same fin with an adiabatic tip  
 (b) The heat transfer from an equivalent fin which is infinitely long  
 (c) The heat transfer from the same fin if the temperature along the entire length of the fin is the same as the base temperature  
 (d) The heat transfer through the base area of the same fin  
 (e) None of the above

**3–223** Computer memory chips are mounted on a finned metallic mount to protect them from overheating. A 152 MB memory chip dissipates  $5 \text{ W}$  of heat to air at  $25^\circ\text{C}$ . If the temperature of this chip is to not exceed  $50^\circ\text{C}$ , the overall heat transfer coefficient-area product of the finned metal mount must be at least

- (a)  $0.2 \text{ W}/^\circ\text{C}$       (b)  $0.3 \text{ W}/^\circ\text{C}$       (c)  $0.4 \text{ W}/^\circ\text{C}$   
 (d)  $0.5 \text{ W}/^\circ\text{C}$       (e)  $0.6 \text{ W}/^\circ\text{C}$

**3–224** In the United States, building insulation is specified by the  $R$ -value (thermal resistance in  $\text{h}\cdot\text{ft}^2\cdot^\circ\text{F}/\text{Btu}$  units). A homeowner decides to save on the cost of heating the home by adding additional insulation in the attic. If the total  $R$ -value is increased from 15 to 25, the homeowner can expect the heat loss through the ceiling to be reduced by

- (a) 25%      (b) 40%      (c) 50%      (d) 60%      (e) 75%

**3–225** A triangular shaped fin on a motorcycle engine is 0.5-cm thick at its base and 3-cm long (normal distance between the base and the tip of the triangle), and is made of aluminum ( $k = 150 \text{ W/m}\cdot\text{K}$ ). This fin is exposed to air with a convective heat transfer coefficient of  $30 \text{ W/m}^2\cdot\text{K}$  acting on its surfaces. The efficiency of the fin is 50 percent. If the base temperature is  $130^\circ\text{C}$  and the air temperature is  $25^\circ\text{C}$ , the heat transfer from this fin per unit width is

- (a)  $32 \text{ W/m}$       (b)  $47 \text{ W/m}$       (c)  $68 \text{ W/m}$   
 (d)  $82 \text{ W/m}$       (e)  $95 \text{ W/m}$

**3–226** A plane brick wall ( $k = 0.7 \text{ W/m}\cdot\text{K}$ ) is 10 cm thick. The thermal resistance of this wall per unit of wall area is

- (a)  $0.143 \text{ m}^2\cdot\text{K/W}$       (b)  $0.250 \text{ m}^2\cdot\text{K/W}$   
 (c)  $0.327 \text{ m}^2\cdot\text{K/W}$       (d)  $0.448 \text{ m}^2\cdot\text{K/W}$   
 (e)  $0.524 \text{ m}^2\cdot\text{K/W}$

### Design and Essay Problems

**3–227** The temperature in deep space is close to absolute zero, which presents thermal challenges for the astronauts who do space walks. Propose a design for the clothing of the astronauts that will be most suitable for the thermal environment in space. Defend the selections in your design.

**3–228** In the design of electronic components, it is very desirable to attach the electronic circuitry to a substrate material that is a very good thermal conductor but also a very effective electrical insulator. If the high cost is not a major concern, what material would you propose for the substrate?

**3-229** Using cylindrical samples of the same material, devise an experiment to determine the thermal contact resistance. Cylindrical samples are available at any length, and the thermal conductivity of the material is known.

**3-230** Find out about the wall construction of the cabins of large commercial airplanes, the range of ambient conditions under which they operate, typical heat transfer coefficients on the inner and outer surfaces of the wall, and the heat generation rates inside. Determine the size of the heating and air-conditioning system that will be able to maintain the cabin at 20°C at all times for an airplane capable of carrying 400 people.

**3-231** Repeat Prob. 3-230 for a submarine with a crew of 60 people.

**3-232** A house with 200-m<sup>2</sup> floor space is to be heated with geothermal water flowing through pipes laid in the ground under the floor. The walls of the house are 4 m high, and there are 10 single-paned windows in the house that are 1.2 m wide and 1.8 m high. The house has *R*-19 (in h·ft<sup>2</sup>·°F/Btu) insulation in the walls and *R*-30 on the ceiling. The floor temperature is

not to exceed 40°C. Hot geothermal water is available at 90°C, and the inner and outer diameter of the pipes to be used are 2.4 cm and 3.0 cm. Design such a heating system for this house in your area.

**3-233** Using a timer (or watch) and a thermometer, conduct this experiment to determine the rate of heat gain of your refrigerator. First, make sure that the door of the refrigerator is not opened for at least a few hours to make sure that steady operating conditions are established. Start the timer when the refrigerator stops running and measure the time  $\Delta t_1$  it stays off before it kicks in. Then measure the time  $\Delta t_2$  it stays on. Noting that the heat removed during  $\Delta t_2$  is equal to the heat gain of the refrigerator during  $\Delta t_1 + \Delta t_2$  and using the power consumed by the refrigerator when it is running, determine the average rate of heat gain for your refrigerator, in watts. Take the COP (coefficient of performance) of your refrigerator to be 1.3 if it is not available.

Now, clean the condenser coils of the refrigerator and remove any obstacles on the way of airflow through the coils. By replacing these measurements, determine the improvement in the COP of the refrigerator.

# TRANSIENT HEAT CONDUCTION

The temperature of a body, in general, varies with time as well as position. In rectangular coordinates, this variation is expressed as  $T(x, y, z, t)$ , where  $(x, y, z)$  indicate variation in the  $x$ -,  $y$ -, and  $z$ -directions, and  $t$  indicates variation with time. In the preceding chapter, we considered heat conduction under *steady* conditions, for which the temperature of a body at any point does not change with time. This certainly simplified the analysis, especially when the temperature varied in one direction only, and we were able to obtain analytical solutions. In this chapter, we consider the variation of temperature with *time* as well as *position* in one- and multidimensional systems.

We start this chapter with the analysis of *lumped systems* in which the temperature of a body varies with time but remains uniform throughout at any time. Then we consider the variation of temperature with time as well as position for one-dimensional heat conduction problems such as those associated with a large plane wall, a long cylinder, a sphere, and a semi-infinite medium using *transient temperature charts* and analytical solutions. Finally, we consider transient heat conduction in multidimensional systems by utilizing the *product solution*.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Assess when the spatial variation of temperature is negligible, and temperature varies nearly uniformly with time, making the simplified lumped system analysis applicable,
- Obtain analytical solutions for transient one-dimensional conduction problems in rectangular, cylindrical, and spherical geometries using the method of separation of variables, and understand why a one-term solution is usually a reasonable approximation,
- Solve the transient conduction problem in large mediums using the similarity variable, and predict the variation of temperature with time and distance from the exposed surface, and
- Construct solutions for multi-dimensional transient conduction problems using the product solution approach.

(a) Copper ball

**FIGURE 4–1**

A small copper ball can be modeled as a lumped system, but a roast beef cannot.

**FIGURE 4–2**

The geometry and parameters involved in the lumped system analysis.

## 4–1 ■ LUMPED SYSTEM ANALYSIS

In heat transfer analysis, some bodies are observed to behave like a “lump” whose interior temperature remains essentially uniform at any times during a heat transfer process. The temperature of such bodies can be taken to be a function of time only,  $T(t)$ . Heat transfer analysis that utilizes this idealization is known as **lumped system analysis**, which provides great simplification in certain classes of heat transfer problems without much sacrifice from accuracy.

Consider a small hot copper ball coming out of an oven (Fig. 4–1). Measurements indicate that the temperature of the copper ball changes with time, but it does not change much with position at any given time. Thus the temperature of the ball remains nearly uniform at all times, and we can talk about the temperature of the ball with no reference to a specific location.

Now let us go to the other extreme and consider a large roast in an oven. If you have done any roasting, you must have noticed that the temperature distribution within the roast is not even close to being uniform. You can easily verify this by taking the roast out before it is completely done and cutting it in half. You will see that the outer parts of the roast are well done while the center part is barely warm. Thus, lumped system analysis is not applicable in this case. Before presenting a criterion about applicability of lumped system analysis, we develop the formulation associated with it.

Consider a body of arbitrary shape of mass  $m$ , volume  $V$ , surface area  $A_s$ , density  $\rho$ , and specific heat  $c_p$  initially at a uniform temperature  $T_i$  (Fig. 4–2). At time  $t = 0$ , the body is placed into a medium at temperature  $T_\infty$ , and heat transfer takes place between the body and its environment, with a heat transfer coefficient  $h$ . For the sake of discussion, we assume that  $T_\infty > T_i$ , but the analysis is equally valid for the opposite case. We assume lumped system analysis to be applicable, so that the temperature remains uniform within the body at all times and changes with time only,  $T = T(t)$ .

During a differential time interval  $dt$ , the temperature of the body rises by a differential amount  $dT$ . An energy balance of the solid for the time interval  $dt$  can be expressed as

$$\left( \begin{array}{c} \text{Heat transfer into the body} \\ \text{during } dt \end{array} \right) = \left( \begin{array}{c} \text{The increase in the} \\ \text{energy of the body} \\ \text{during } dt \end{array} \right)$$

or

$$hA_s(T_\infty - T) dt = mc_p dT \quad (4-1)$$

Noting that  $m = \rho V$  and  $dT = d(T - T_\infty)$  since  $T_\infty = \text{constant}$ , Eq. 4–1 can be rearranged as

$$\frac{d(T - T_\infty)}{T - T_\infty} = -\frac{hA_s}{\rho V c_p} dt \quad (4-2)$$

Integrating from  $t = 0$ , at which  $T = T_i$ , to any time  $t$ , at which  $T = T(t)$ , gives

$$\ln \frac{T(t) - T_\infty}{T_i - T_\infty} = -\frac{hA_s}{\rho V c_p} t \quad (4-3)$$

Taking the exponential of both sides and rearranging, we obtain

$$\frac{T(t) - T_{\infty}}{T_i - T_{\infty}} = e^{-bt} \quad (4-4)$$

where

$$b = \frac{hA_s}{\rho V c_p} \quad (\text{1/s}) \quad (4-5)$$

is a positive quantity whose dimension is  $(\text{time})^{-1}$ . The reciprocal of  $b$  has time unit (usually s), and is called the **time constant**. Equation 4-4 is plotted in Fig. 4-3 for different values of  $b$ . There are two observations that can be made from this figure and the relation above:

1. Equation 4-4 enables us to determine the temperature  $T(t)$  of a body at time  $t$ , or alternatively, the time  $t$  required for the temperature to reach a specified value  $T(t)$ .
  2. The temperature of a body approaches the ambient temperature  $T_{\infty}$  exponentially. The temperature of the body changes rapidly at the beginning, but rather slowly later on. A large value of  $b$  indicates that the body approaches the environment temperature in a short time. The larger the value of the exponent  $b$ , the higher the rate of decay in temperature.
- Note that  $b$  is proportional to the surface area, but inversely proportional to the mass and the specific heat of the body. This is not surprising since it takes longer to heat or cool a larger mass, especially when it has a large specific heat.

Once the temperature  $T(t)$  at time  $t$  is available from Eq. 4-4, the *rate* of convection heat transfer between the body and its environment at that time can be determined from Newton's law of cooling as

$$\dot{Q}(t) = hA_s[T(t) - T_{\infty}] \quad (\text{W}) \quad (4-6)$$

The *total amount* of heat transfer between the body and the surrounding medium over the time interval  $t = 0$  to  $t$  is simply the change in the energy content of the body:

$$Q = mc_p[T(t) - T_i] \quad (\text{kJ}) \quad (4-7)$$

The amount of heat transfer reaches its upper limit when the body reaches the surrounding temperature  $T_{\infty}$ . Therefore, the *maximum* heat transfer between the body and its surroundings is (Fig. 4-4)

$$Q_{\max} = mc_p(T_{\infty} - T_i) \quad (\text{kJ}) \quad (4-8)$$

We could also obtain this equation by substituting the  $T(t)$  relation from Eq. 4-4 into the  $\dot{Q}(t)$  relation in Eq. 4-6 and integrating it from  $t = 0$  to  $t \rightarrow \infty$ .

## Criteria for Lumped System Analysis

The lumped system analysis certainly provides great convenience in heat transfer analysis, and naturally we would like to know when it is appropriate

**FIGURE 4-3**

The temperature of a lumped system approaches the environment temperature as time gets larger.

**FIGURE 4-4**

Heat transfer to or from a body reaches its maximum value when the body reaches the environment temperature.

**FIGURE 4–5**

**Jean-Baptiste Biot** (1774–1862) was a French physicist, astronomer, and mathematician born in Paris, France. Although younger, Biot worked on the analysis of heat conduction even earlier than Fourier did (1802 or 1803) and attempted, unsuccessfully, to deal with the problem of incorporating external convection effects in heat conduction analysis. Fourier read Biot's work and by 1807 had determined for himself how to solve the elusive problem. In 1804, Biot accompanied Gay Lussac on the first balloon ascent undertaken for scientific purposes. In 1820, with Félix Savart, he discovered the law known as “Biot and Savart’s Law.” He was especially interested in questions relating to the polarization of light, and for his achievements in this field he was awarded the Rumford Medal of the Royal Society in 1840. The dimensionless **Biot number (Bi)** used in transient heat transfer calculations is named after him.

© World History Archive/Alamy.

to use it. The first step in establishing a criterion for the applicability of the lumped system analysis is to define a **characteristic length** as

$$L_c = \frac{V}{A_s}$$

and a dimensionless **Biot number** (Fig. 4–5) Bi as

$$Bi = \frac{hL_c}{k} \quad (4-9)$$

The characteristic length  $L_c$  to be used in the Biot number for simple geometries in which heat transfer is one-dimensional, such as a large plane wall of thickness  $2L$ , a long cylinder of radius  $r_o$ , and a sphere of radius  $r_o$ , becomes  $L$  (half thickness),  $r_o/2$ , and  $r_o/3$ , respectively. Equation 4–9 can also be expressed as (Fig. 4–6).

$$Bi = \frac{h}{k/L_c} \frac{\Delta T}{\Delta T} = \frac{\text{Convection at the surface of the body}}{\text{Conduction within the body}}$$

or

$$Bi = \frac{L_c/k}{1/h} = \frac{\text{Conduction resistance within the body}}{\text{Convection resistance at the surface of the body}}$$

When a solid body is being heated by the hotter fluid surrounding it (such as a potato being baked in an oven), heat is first *convected* to the body and subsequently *conducted* within the body. The Biot number is the *ratio* of the internal resistance of a body to *heat conduction* to its external resistance to *heat convection*. Therefore, a small Biot number represents small resistance to heat conduction, and thus small temperature gradients within the body.

Lumped system analysis assumes a *uniform* temperature distribution throughout the body, which is the case only when the thermal resistance of the body to heat conduction (the *conduction resistance*) is zero. Thus, lumped system analysis is *exact* when  $Bi = 0$  and *approximate* when  $Bi > 0$ . Of course, the smaller the Bi number, the more accurate the lumped system analysis. Then the question we must answer is, how much accuracy are we willing to sacrifice for the convenience of the lumped system analysis?

Before answering this question, we should mention that a 15 percent uncertainty in the convection heat transfer coefficient  $h$  in most cases is considered “normal” and “expected.” Assuming  $h$  to be *constant* and *uniform* is also an approximation of questionable validity, especially for irregular geometries. Therefore, in the absence of sufficient experimental data for the specific geometry under consideration, we cannot claim our results to be better than  $\pm 15$  percent, even when  $Bi = 0$ . This being the case, introducing another source of uncertainty in the problem will not have much effect on the overall uncertainty, provided that it is minor. It is generally accepted that lumped system analysis is *applicable* if

$$Bi \leq 0.1$$

When this criterion is satisfied, the temperatures within the body relative to the surroundings (i.e.,  $T - T_\infty$ ) remain within 5 percent of each other even for well-rounded geometries such as a spherical ball. Thus, when  $Bi < 0.1$ ,

the variation of temperature with location within the body is slight and can reasonably be approximated as being uniform.

The first step in the application of lumped system analysis is the calculation of the *Biot number*, and the assessment of the applicability of this approach. One may still wish to use lumped system analysis even when the criterion  $\text{Bi} < 0.1$  is not satisfied, if high accuracy is not a major concern.

Note that the Biot number is the ratio of the *convection* at the surface to *conduction* within the body, and this number should be as small as possible for lumped system analysis to be applicable. Therefore, *small bodies with high thermal conductivity* are good candidates for lumped system analysis, especially when they are in a medium that is a poor conductor of heat (such as air or another gas) and motionless. Thus, the hot small copper ball placed in quiescent air, discussed earlier, is most likely to satisfy the criterion for lumped system analysis (Fig. 4–7).

## Some Remarks on Heat Transfer in Lumped Systems

To understand the heat transfer mechanism during the heating or cooling of a solid by the fluid surrounding it, and the criterion for lumped system analysis, consider this analogy (Fig. 4–8). People from the mainland are to go by *boat* to an island whose entire shore is a harbor, and from the harbor to their destinations on the island by *bus*. The overcrowding of people at the harbor depends on the boat traffic to the island and the ground transportation system on the island. If there is an excellent ground transportation system with plenty of buses, there will be no overcrowding at the harbor, especially when the boat traffic is light. But when the opposite is true, there will be a huge overcrowding at the harbor, creating a large difference between the populations at the harbor and inland. The chance of overcrowding is much lower in a small island with plenty of fast buses.

In heat transfer, a poor ground transportation system corresponds to poor heat conduction in a body, and overcrowding at the harbor to the accumulation of thermal energy and the subsequent rise in temperature near the surface of the body relative to its inner parts. Lumped system analysis is obviously not applicable when there is overcrowding at the surface. Of course, we have disregarded radiation in this analogy and thus the air traffic to the island. Like passengers at the harbor, heat changes *vehicles* at the surface from *convection* to *conduction*. Noting that a surface has zero thickness and thus cannot store any energy, heat reaching the surface of a body by convection must continue its journey within the body by conduction.

Consider heat transfer from a hot body to its cooler surroundings. Heat is transferred from the body to the surrounding fluid as a result of a temperature difference. But this energy comes from the region near the surface, and thus the temperature of the body near the surface will drop. This creates a *temperature gradient* between the inner and outer regions of the body and initiates heat transfer by conduction from the interior of the body toward the outer surface.

When the convection heat transfer coefficient  $h$  and thus the rate of convection from the body are high, the temperature of the body near the surface drops quickly (Fig. 4–9). This creates a larger temperature difference between the inner and outer regions unless the body is able to transfer heat from the inner to the outer regions just as fast. Thus, the magnitude of the maximum temperature

FIGURE 4–6

The Biot number can be viewed as the ratio of the convection at the surface to conduction within the body.

$$L_c = \frac{V}{A_s} = \frac{\frac{1}{6}\pi D^3}{\pi D^2} = \frac{1}{6}D = 0.02 \text{ m}$$

$$\text{Bi} = \frac{hL_c}{k} = \frac{15 \times 0.02}{401} = 0.00075 < 0.1$$

FIGURE 4–7

Small bodies with high thermal conductivities and low convection coefficients are most likely to satisfy the criterion for lumped system analysis.

FIGURE 4–8

Analogy between heat transfer to a solid and passenger traffic to an island.

**FIGURE 4-9**

When the convection coefficient  $h$  is high and  $k$  is low, large temperature differences occur between the inner and outer regions of a large solid.

**FIGURE 4-10**

Schematic for Example 4-1.

difference within the body depends strongly on the ability of a body to conduct heat toward its surface relative to the ability of the surrounding medium to convect heat away from the surface. The Biot number is a measure of the relative magnitudes of these two competing effects.

Recall that heat conduction in a specified direction  $n$  per unit surface area is expressed as  $\dot{q} = -k \partial T / \partial n$ , where  $\partial T / \partial n$  is the temperature gradient and  $k$  is the thermal conductivity of the solid. Thus, the temperature distribution in the body will be *uniform* only when its thermal conductivity is *infinite*, and no such material is known to exist. Therefore, temperature gradients and thus temperature differences must exist within the body, no matter how small, in order for heat conduction to take place. Of course, the temperature gradient and the thermal conductivity are inversely proportional for a given heat flux. Therefore, the larger the thermal conductivity, the smaller the temperature gradient.

### EXAMPLE 4-1 Temperature Measurement by Thermocouples

The temperature of a gas stream is to be measured by a thermocouple whose junction can be approximated as a 1-mm-diameter sphere, as shown in Fig. 4-10. The properties of the junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ , and the convection heat transfer coefficient between the junction and the gas is  $h = 210 \text{ W/m}^2\cdot\text{K}$ . Determine how long it will take for the thermocouple to read 99 percent of the initial temperature difference.

**SOLUTION** The temperature of a gas stream is to be measured by a thermocouple. The time it takes to register 99 percent of the initial  $\Delta T$  is to be determined.

**Assumptions** 1 The junction is spherical in shape with a diameter of  $D = 0.001 \text{ m}$ . 2 The thermal properties of the junction and the heat transfer coefficient are constant. 3 Radiation effects are negligible.

**Properties** The properties of the junction are given in the problem statement.

**Analysis** The characteristic length of the junction is

$$L_c = \frac{V}{A_s} = \frac{\frac{1}{6}\pi D^3}{\pi D^2} = \frac{1}{6}D = \frac{1}{6}(0.001 \text{ m}) = 1.67 \times 10^{-4} \text{ m}$$

Then the Biot number becomes

$$\text{Bi} = \frac{hL_c}{k} = \frac{(210 \text{ W/m}^2\cdot\text{K})(1.67 \times 10^{-4} \text{ m})}{35 \text{ W/m}\cdot\text{K}} = 0.001 < 0.1$$

Therefore, lumped system analysis is applicable, and the error involved in this approximation is negligible.

In order to read 99 percent of the initial temperature difference  $T_i - T_{\infty}$  between the junction and the gas, we must have

$$\frac{T(t) - T_{\infty}}{T_i - T_{\infty}} = 0.01$$

For example, when  $T_i = 0^{\circ}\text{C}$  and  $T_{\infty} = 100^{\circ}\text{C}$ , a thermocouple is considered to have read 99 percent of this applied temperature difference when its reading indicates  $T(t) = 99^{\circ}\text{C}$ .

The value of the exponent  $b$  is

$$b = \frac{hA_s}{\rho c_p V} = \frac{h}{\rho c_p L_c} = \frac{210 \text{ W/m}^2 \cdot \text{K}}{(8500 \text{ kg/m}^3)(320 \text{ J/kg} \cdot \text{K})(1.67 \times 10^{-4} \text{ m})} = 0.462 \text{ s}^{-1}$$

We now substitute these values into Eq. 4–4 and obtain

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt} \quad \longrightarrow \quad 0.01 = e^{-(0.462 \text{ s}^{-1})t}$$

which yields

$$t = 10 \text{ s}$$

Therefore, we must wait at least 10 s for the temperature of the thermocouple junction to approach within 99 percent of the initial junction-gas temperature difference.

**Discussion** Note that conduction through the wires and radiation exchange with the surrounding surfaces affect the result, and should be considered in a more refined analysis.

### PtD EXAMPLE 4–2

### Air Cooling of Metal Plates

Metal plates ( $k = 180 \text{ W/m} \cdot \text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg} \cdot \text{K}$ ) with a thickness of 2 cm exiting an oven are conveyed through a 10-m long cooling chamber at a speed of 4 cm/s (Fig. 4–11). The plates enter the cooling chamber at an initial temperature of 700°C. The air temperature in the cooling chamber is 15°C, and the plates are cooled with blowing air and the convection heat transfer coefficient is given as a function of the air velocity  $h = 33V^{0.8}$ , where  $h$  is in  $\text{W/m}^2 \cdot \text{K}$  and  $V$  is in m/s. To prevent any incident of thermal burn, it is necessary to design the cooling process such that the plates exit the cooling chamber at a relatively safe temperature of 50°C or less. Determine the air velocity and the heat transfer coefficient such that the temperature of the plates exiting the cooling chamber is at 50°C.

**SOLUTION** In this example, the concepts of Prevention through Design (PtD) are applied in conjunction with lumped system analysis. Metal plates exiting an oven are being cooled by air in a cooling chamber. The air velocity and convection heat transfer coefficient that are required to cool the plates so that they exit the cooling chamber at 50°C are to be determined.

**Assumptions** 1 The thermal properties of metal plates are constant. 2 Convection heat transfer coefficient is uniform. 3 Heat transfer by radiation is negligible. 4 The Biot number is  $\text{Bi} < 0.1$  so that the lumped system analysis is applicable (this assumption will be verified).

**Properties** The properties of the metal plates are given as  $k = 180 \text{ W/m} \cdot \text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg} \cdot \text{K}$ .

**Analysis** The characteristic length and the Biot number of the metal plate are

$$L_c = \frac{V}{A_s} = \frac{2LA}{2A} = L = \frac{20 \text{ mm}}{2} = 10 \text{ mm}$$

**FIGURE 4–11**  
Schematic for Example 4–2.

Using the lumped system analysis,

$$b = \frac{hA_s}{\rho c_p V} = \frac{h}{\rho c_p L_c} = \frac{33V_{\text{air}}^{0.8}}{\rho c_p L_c} = \frac{33V_{\text{air}}^{0.8}}{(2800 \text{ kg/m}^3)(880 \text{ J/kg}\cdot\text{K})(0.010 \text{ m})}$$

The duration of cooling can be determined from the cooling chamber length and the speed of the plates,

$$t = \frac{10 \text{ m}}{0.04 \text{ m/s}} = 250 \text{ s}$$

$$\begin{aligned} \frac{T(t) - T_\infty}{T_i - T_\infty} &= e^{-bt} \rightarrow b = -\frac{1}{t} \ln \left[ \frac{T(t) - T_\infty}{T_i - T_\infty} \right] \\ &= -\frac{1}{250 \text{ s}} \ln \left( \frac{50 - 15}{700 - 15} \right) = 0.0119 \text{ s}^{-1} \end{aligned}$$

Thus, the air velocity and convection heat transfer coefficient necessary to cool the plates to 50°C as they exit the cooling chamber is

$$\begin{aligned} b &= \frac{33V_{\text{air}}^{0.8}}{\rho c_p L_c} = 0.01195 \text{ s}^{-1} \\ V_{\text{air}} &= \left[ \frac{(0.0119 \text{ s}^{-1})(2800 \text{ kg/m}^3)(880 \text{ J/kg}\cdot\text{K})(0.010 \text{ m})}{33} \right]^{1/0.8} = 15.3 \text{ m/s} \\ h &= 33V_{\text{air}}^{0.8} = 33(15.3 \text{ m/s})^{0.8} = 293 \text{ W/m}^2\cdot\text{K} \end{aligned}$$

Since this analysis was carried out under the assumption that it is a lumped system, and for this assumption to be applicable, the condition  $\text{Bi} < 0.1$  needs to be satisfied

$$\text{Bi} = \frac{hL_c}{k} = \frac{(293 \text{ W/m}^2\cdot\text{K})(0.010 \text{ m})}{180 \text{ W/m}\cdot\text{K}} = 0.0163 < 0.1$$

**Discussion** The effect of the air velocity on the temperature of the plates exiting the cooling chamber is plotted in Fig. 4–12. The figure shows that for air velocities less than 15.3 m/s the temperature of the plates stays well below 50°C which should prevent any incident of thermal burn.

FIGURE 4–12

Variation of plate temperature with the air velocity at the exit of the cooling chamber.

## 4–2 • TRANSIENT HEAT CONDUCTION IN LARGE PLANE WALLS, LONG CYLINDERS, AND SPHERES WITH SPATIAL EFFECTS

In Section 4–1, we considered bodies in which the variation of temperature within the body is negligible; that is, bodies that remain nearly *isothermal* during a process. Relatively small bodies of highly conductive materials approximate this behavior. In general, however, the temperature within a body changes from point to point as well as with time. In this section, we consider the variation of temperature with *time* and *position* in one-dimensional problems such as those associated with a large plane wall, a long cylinder, and a sphere.

Consider a plane wall of thickness  $2L$ , a long cylinder of radius  $r_o$ , and a sphere of radius  $r_o$  initially at a *uniform temperature*  $T_i$ , as shown in Fig. 4–13. At time  $t = 0$ , each geometry is placed in a large medium that is at a constant

**FIGURE 4-13**

Schematic of the simple geometries in which heat transfer is one-dimensional.

temperature  $T_\infty$  and kept in that medium for  $t > 0$ . Heat transfer takes place between these bodies and their environments by convection with a *uniform* and *constant* heat transfer coefficient  $h$ . Note that all three cases possess geometric and thermal symmetry: the plane wall is symmetric about its *center plane* ( $x = 0$ ), the cylinder is symmetric about its *centerline* ( $r = 0$ ), and the sphere is symmetric about its *center point* ( $r = 0$ ). We neglect *radiation* heat transfer between these bodies and their surrounding surfaces, or incorporate the radiation effect into the convection heat transfer coefficient  $h$ .

The variation of the temperature profile with *time* in the plane wall is illustrated in Fig. 4-14. When the wall is first exposed to the surrounding medium at  $T_\infty < T_i$  at  $t = 0$ , the entire wall is at its initial temperature  $T_i$ . But the wall temperature at and near the surfaces starts to drop as a result of heat transfer from the wall to the surrounding medium. This creates a *temperature gradient* in the wall and initiates heat conduction from the inner parts of the wall toward its outer surfaces. Note that the temperature at the center of the wall remains at  $T_i$  until  $t = t_2$ , and that the temperature profile within the wall remains symmetric at all times about the center plane. The temperature profile gets flatter and flatter as time passes as a result of heat transfer, and eventually becomes uniform at  $T = T_\infty$ . That is, the wall reaches *thermal equilibrium* with its surroundings. At that point, heat transfer stops since there is no longer a temperature difference. Similar discussions can be given for the long cylinder or sphere.

## Nondimensionalized One-Dimensional Transient Conduction Problem

The formulation of heat conduction problems for the determination of the one-dimensional transient temperature distribution in a plane wall, a cylinder, or a sphere results in a partial differential equation whose solution typically involves infinite series and transcendental equations, which are inconvenient to use. But the analytical solution provides valuable insight to the physical problem, and thus it is important to go through the steps involved. Below we demonstrate the solution procedure for the case of plane wall.

Consider a plane wall of thickness  $2L$  initially at a uniform temperature of  $T_i$ , as shown in Fig. 4-13a. At time  $t = 0$ , the wall is immersed in a fluid at temperature  $T_\infty$  and is subjected to convection heat transfer from both sides with a convection coefficient of  $h$ . The height and the width of the wall are large relative to its thickness, and thus heat conduction in the wall can be

**FIGURE 4-14**

Transient temperature profiles in a plane wall exposed to convection from its surfaces for  $T_i > T_\infty$ .

approximated to be one-dimensional. Also, there is thermal symmetry about the midplane passing through  $x = 0$ , and thus the temperature distribution must be symmetrical about the midplane. Therefore, the value of temperature at any  $-x$  value in  $-L \leq x \leq 0$  at any time  $t$  must be equal to the value at  $+x$  in  $0 \leq x \leq L$  at the same time. This means we can formulate and solve the heat conduction problem in the positive half domain  $0 \leq x \leq L$ , and then apply the solution to the other half.

Under the conditions of constant thermophysical properties, no heat generation, thermal symmetry about the midplane, uniform initial temperature, and constant convection coefficient, the one-dimensional transient heat conduction problem in the half-domain  $0 \leq x \leq L$  of the plane wall can be expressed as (see Chapter 2)

$$\text{Differential equation: } \frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (4-10a)$$

$$\text{Boundary conditions: } \frac{\partial T(0, t)}{\partial x} = 0 \quad \text{and} \quad -k \frac{\partial T(L, t)}{\partial x} = h[T(L, t) - T_\infty] \quad (4-10b)$$

$$\text{Initial condition: } T(x, 0) = T_i \quad (4-10c)$$

where the property  $\alpha = k/\rho c_p$  is the thermal diffusivity of the material.

We now attempt to nondimensionalize the problem by defining a dimensionless space variable  $X = x/L$  and dimensionless temperature  $\theta(x, t) = [T(x, t) - T_\infty]/[T_i - T_\infty]$ . These are convenient choices since both  $X$  and  $\theta$  vary between 0 and 1. However, there is no clear guidance for the proper form of the dimensionless time variable and the  $h/k$  ratio, so we will let the analysis indicate them. We note that

$$\frac{\partial \theta}{\partial X} = \frac{\partial \theta}{\partial (x/L)} = \frac{L}{T_i - T_\infty} \frac{\partial T}{\partial x}, \quad \frac{\partial^2 \theta}{\partial X^2} = \frac{L^2}{T_i - T_\infty} \frac{\partial^2 T}{\partial x^2} \quad \text{and} \quad \frac{\partial \theta}{\partial t} = \frac{1}{T_i - T_\infty} \frac{\partial T}{\partial t}$$

Substituting into Eqs. 4-10a and 4-10b and rearranging give

$$\frac{\partial^2 \theta}{\partial X^2} = \frac{L^2}{\alpha} \frac{\partial \theta}{\partial t} \quad \text{and} \quad \frac{\partial \theta(1, t)}{\partial X} = \frac{hL}{k} \theta(1, t) \quad (4-11)$$

Therefore, the proper form of the dimensionless time is  $\tau = \alpha t/L^2$ , which is called the **Fourier number**  $Fo$  (named after Jean Baptiste Joseph Fourier, see Fig. 1-27), and we recognize  $Bi = hL/k$  as the Biot number defined in Section 4-1. Then the formulation of the one-dimensional transient heat conduction problem in a plane wall can be expressed in nondimensional form as

$$\text{Dimensionless differential equation: } \frac{\partial^2 \theta}{\partial X^2} = \frac{\partial \theta}{\partial \tau} \quad (4-12a)$$

$$\text{Dimensionless BC's: } \frac{\partial \theta(0, \tau)}{\partial X} = 0 \quad \text{and} \quad \frac{\partial \theta(1, \tau)}{\partial X} = -Bi\theta(1, \tau) \quad (4-12b)$$

$$\text{Dimensionless initial condition: } \theta(X, 0) = 1 \quad (4-12c)$$

where

$$\theta(X, \tau) = \frac{T(x, t) - T_\infty}{T_i - T_\infty} \quad \text{Dimensionless temperature}$$

$$X = \frac{x}{L} \quad \text{Dimensionless distance from the center}$$

$$\text{Bi} = \frac{hL}{k}$$

*Dimensionless heat transfer coefficient (Biot number)*

$$\tau = \frac{\alpha t}{L^2} = \text{Fo}$$

*Dimensionless time (Fourier number)*

The heat conduction equation in cylindrical or spherical coordinates can be nondimensionalized in a similar way. Note that nondimensionalization reduces the number of independent variables and parameters from 8 to 3—from  $x$ ,  $L$ ,  $t$ ,  $k$ ,  $\alpha$ ,  $h$ ,  $T_i$ , and  $T_\infty$  to  $X$ , Bi, and Fo (Fig. 4–15). That is,

$$\theta = f(X, \text{Bi}, \text{Fo}) \quad (4-13)$$

This makes it very practical to conduct parametric studies and avoid results in graphical form. Equation 4–13 is the generalized version of Eq. 4–4 for the lumped system analysis (no space variables). This can be shown by using the definitions of  $\theta$ ,  $\alpha$ ,  $L_c$ , Bi, and Fo in Eq. 4–4. The final result is

$$\theta = \frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt} = e^{-\frac{hA_s t}{\rho V c_p}} = e^{-\text{Bi}\text{Fo}}$$

or  $\theta = f(\text{Fo}, \text{Bi})$  which is the special case of Eq. 4–13 with no space variable.

### Exact Solution of One-Dimensional Transient Conduction Problem\*

The non-dimensionalized partial differential equation given in Eqs. 4–12 together with its boundary and initial conditions can be solved using several analytical and numerical techniques, including the Laplace or other transform methods, the method of separation of variables, the finite difference method, and the finite-element method. Here we use the method of **separation of variables** developed by J. Fourier in the 1820s and is based on expanding an arbitrary function (including a constant) in terms of Fourier series. The method is applied by assuming the dependent variable to be a product of a number of functions, each being a function of a single independent variable. This reduces the partial differential equation to a system of ordinary differential equations, each being a function of a single independent variable. In the case of transient conduction in a plane wall, for example, the dependent variable is the solution function  $\theta(X, \tau)$ , which is expressed as  $\theta(X, \tau) = F(X)G(\tau)$ , and the application of the method results in two ordinary differential equation, one in  $X$  and the other in  $\tau$ .

The method is applicable if (1) the geometry is simple and finite (such as a rectangular block, a cylinder, or a sphere) so that the boundary surfaces can be described by simple mathematical functions, and (2) the differential equation and the boundary and initial conditions in their most simplified form are linear (no terms that involve products of the dependent variable or its derivatives) and involve only one nonhomogeneous term (a term without the dependent variable or its derivatives). If the formulation involves a number of nonhomogeneous terms, the problem can be split up into an equal number of simpler problems each involving only one nonhomogeneous term, and then combining the solutions by superposition.

Now we demonstrate the use of the method of separation of variables by applying it to the one-dimensional transient heat conduction problem given in

(a) Original heat conduction problem:

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial x}, \quad T(x, 0) = T_i$$

$$\frac{\partial T(0, t)}{\partial x} = 0, \quad -k \frac{\partial T(L, t)}{\partial x} = h[T(L, t) - T_\infty] \\ T = F(x, L, t, k, \alpha, h, T_i, T_\infty)$$

(b) Nondimensionalized problem:

$$\frac{\partial^2 \theta}{\partial X^2} = \frac{\partial \theta}{\partial \tau}, \quad \theta(X, 0) = 1$$

$$\frac{\partial \theta(0, \tau)}{\partial X} = 0, \quad \frac{\partial \theta(1, \tau)}{\partial X} = -\text{Bi}\theta(1, \tau) \\ \theta = f(X, \text{Bi}, \tau)$$

**FIGURE 4–15**

Nondimensionalization reduces the number of independent variables in one-dimensional transient conduction problems from 8 to 3, offering great convenience in the presentation of results.

\*This section can be skipped if desired without a loss of continuity.

Eqs. 4–12. First, we express the dimensionless temperature function  $\theta(X, \tau)$  as a product of a function of  $X$  only and a function of  $\tau$  only as

$$\theta(X, \tau) = F(X)G(\tau) \quad (4-14)$$

Substituting Eq. 4–14 into Eq. 4–12a and dividing by the product  $FG$  gives

$$\frac{1}{F} \frac{d^2F}{dX^2} = \frac{1}{G} \frac{dG}{d\tau} \quad (4-15)$$

Observe that all the terms that depend on  $X$  are on the left-hand side of the equation and all the terms that depend on  $\tau$  are on the right-hand side. That is, the terms that are function of different variables are *separated* (and thus the name *separation of variables*). The left-hand side of this equation is a function of  $X$  only and the right-hand side is a function of only  $\tau$ . Considering that both  $X$  and  $\tau$  can be varied independently, the equality in Eq. 4–15 can hold for any value of  $X$  and  $\tau$  only if Eq. 4–15 is equal to a constant. Further, it must be a *negative* constant that we will indicate by  $-\lambda^2$  since a positive constant will cause the function  $G(\tau)$  to increase indefinitely with time (to be infinite), which is unphysical, and a value of zero for the constant means no time dependence, which is again inconsistent with the physical problem. Setting Eq. 4–15 equal to  $-\lambda^2$  gives

$$\frac{d^2F}{dX^2} + \lambda^2F = 0 \quad \text{and} \quad \frac{dG}{d\tau} + \lambda^2G = 0 \quad (4-16)$$

whose general solutions are

$$F = C_1 \cos(\lambda X) + C_2 \sin(\lambda X) \quad \text{and} \quad G = C_3 e^{-\lambda^2 \tau} \quad (4-17)$$

and

$$\theta = FG = C_3 e^{-\lambda^2 \tau} [C_1 \cos(\lambda X) + C_2 \sin(\lambda X)] = e^{-\lambda^2 \tau} [A \cos(\lambda X) + B \sin(\lambda X)] \quad (4-18)$$

where  $A = C_1 C_3$  and  $B = C_2 C_3$  are arbitrary constants. Note that we need to determine only  $A$  and  $B$  to obtain the solution of the problem.

Applying the boundary conditions in Eq. 4–12b gives

$$\begin{aligned} \frac{\partial \theta(0, \tau)}{\partial X} &= 0 \rightarrow -e^{-\lambda^2 \tau} (A \lambda \sin 0 + B \lambda \cos 0) = \rightarrow B = 0 \rightarrow \theta = A e^{-\lambda^2 \tau} \cos(\lambda X) \\ \frac{\partial \theta(1, \tau)}{\partial X} &= -Bi \theta(1, \tau) \rightarrow -A e^{-\lambda^2 \tau} \lambda \sin \lambda = -Bi A e^{-\lambda^2 \tau} \cos \lambda \rightarrow \lambda \tan \lambda = Bi \end{aligned}$$

But tangent is a periodic function with a period of  $\pi$ , and the equation  $\lambda \tan \lambda = Bi$  has the root  $\lambda_1$  between 0 and  $\pi$ , the root  $\lambda_2$  between  $\pi$  and  $2\pi$ , the root  $\lambda_n$  between  $(n-1)\pi$  and  $n\pi$ , etc. To recognize that the transcendental equation  $\lambda \tan \lambda = Bi$  has an infinite number of roots, it is expressed as

$$\lambda_n \tan \lambda_n = Bi \quad (4-19)$$

Eq. 4–19 is called the **characteristic equation** or **eigenfunction**, and its roots are called the **characteristic values** or **eigenvalues**. The characteristic equation is implicit in this case, and thus the characteristic values need to be determined numerically. Then it follows that there are an infinite number of solutions of the form  $A e^{-\lambda^2 \tau} \cos(\lambda X)$ , and the solution of this linear heat conduction problem is a linear combination of them,

$$\theta = \sum_{n=1}^{\infty} A_n e^{-\lambda_n^2 \tau} \cos(\lambda_n X) \quad (4-20)$$

The constants  $A_n$  are determined from the initial condition, Eq. 4–12c,

$$\theta(X, 0) = 1 \rightarrow 1 = \sum_{n=1}^{\infty} A_n \cos(\lambda_n X) \quad (4-21)$$

This is a Fourier series expansion that expresses a constant in terms of an infinite series of cosine functions. Now we multiply both sides of Eq. 4–21 by  $\cos(\lambda_m X)$ , and integrate from  $X = 0$  to  $X = 1$ . The right-hand side involves an infinite number of integrals of the form  $\int_0^1 \cos(\lambda_m X) \cos(\lambda_n X) dx$ . It can be shown that all of these integrals vanish except when  $n = m$ , and the coefficient  $A_n$  becomes

$$\int_0^1 \cos(\lambda_n X) dX = A_n \int_0^1 \cos^2(\lambda_n X) dX \rightarrow A_n = \frac{4 \sin \lambda_n}{2\lambda_n + \sin(2\lambda_n)} \quad (4-22)$$

This completes the analysis for the solution of one-dimensional transient heat conduction problem in a plane wall. Solutions in other geometries such as a long cylinder and a sphere can be determined using the same approach. The long cylinder approximation allows the assumption of one-dimensional conduction in the radial direction. It is a reasonable approximation for cylinders having length ( $L$ ) to radius ( $r_0$ ) ratio,  $L/r_0 \geq 10$ . The results for all three geometries are summarized in Table 4–1. The solution for the plane wall is also applicable for a plane wall of thickness  $L$  whose left surface at  $x = 0$  is insulated and the right surface at  $x = L$  is subjected to convection since this is precisely the mathematical problem we solved.

The analytical solutions of transient conduction problems typically involve infinite series, and thus the evaluation of an infinite number of terms to determine the temperature at a specified location and time. This may look intimidating at first, but there is no need to worry. As demonstrated in Fig. 4–16, the terms in the summation decline rapidly as  $n$  and thus  $\lambda_n$  increases because of the exponential decay function  $e^{-\lambda_n^2 \tau}$ . This is especially the case when the dimensionless time  $\tau$  is large. Therefore, the evaluation of the first few terms of the infinite series (in this case just the first term) is usually adequate to determine the dimensionless temperature  $\theta$ .

$$\theta_n = A_n e^{-\lambda_n^2 \tau} \cos(\lambda_n X)$$

$$A_n = \frac{4 \sin \lambda_n}{2\lambda_n + \sin(2\lambda_n)}$$

$$\lambda_n \tan \lambda_n = Bi$$

For  $Bi = 5$ ,  $X = 1$ , and  $t = 0.2$ :

| $n$ | $\lambda_n$ | $A_n$   | $\theta_n$ |
|-----|-------------|---------|------------|
| 1   | 1.3138      | 1.2402  | 0.22321    |
| 2   | 4.0336      | -0.3442 | 0.00835    |

FIGURE 4–16

The term in the series solution of transient conduction problems decline rapidly as  $n$  and thus  $\lambda_n$  increases because of the exponential decay function with the exponent  $-\lambda_n \tau$ .

TABLE 4–1

Summary of the solutions for one-dimensional transient conduction in a plane wall of thickness  $2L$ , a cylinder of radius  $r_o$  and a sphere of radius  $r_o$  subjected to convection from all surfaces.\*

| Geometry   | Solution  | $\lambda_n$ 's are the roots of                        |
|------------|---|--|
| Plane wall | $\theta = \sum_{n=1}^{\infty} \frac{4 \sin \lambda_n}{2\lambda_n + \sin(2\lambda_n)} e^{-\lambda_n^2 \tau} \cos(\lambda_n x/L)$   | $\lambda_n \tan \lambda_n = Bi$                        |
| Cylinder   | $\theta = \sum_{n=1}^{\infty} \frac{2}{\lambda_n} \frac{J_1(\lambda_n)}{J_0^2(\lambda_n) + J_1^2(\lambda_n)} e^{-\lambda_n^2 \tau} J_0(\lambda_n r / r_o)$                        | $\lambda_n \frac{J_1(\lambda_n)}{J_0(\lambda_n)} = Bi$ |
| Sphere     | $\theta = \sum_{n=1}^{\infty} \frac{4(\sin \lambda_n - \lambda_n \cos \lambda_n)}{2\lambda_n - \sin(2\lambda_n)} e^{-\lambda_n^2 \tau} \frac{\sin(\lambda_n x/L)}{\lambda_n x/L}$ | $1 - \lambda_n \cot \lambda_n = Bi$                    |

\*Here  $\theta = (T - T_\infty)/(T_i - T_\infty)$  is the dimensionless temperature,  $Bi = hL/k$  or  $hr_o/k$  is the Biot number,  $Fo = \tau = \alpha t / L^2$  or  $\alpha \tau / r_o^2$  is the Fourier number, and  $J_0$  and  $J_1$  are the Bessel functions of the first kind whose values are given in Table 4–3. Note that the characteristic length used for each geometry in the equations for the Biot and Fourier numbers is different for the exact (analytical) solution than the one used for the lumped system analysis.

## Approximate Analytical and Graphical Solutions

The analytical solution obtained above for one-dimensional transient heat conduction in a plane wall involves infinite series and implicit equations, which are difficult to evaluate. Therefore, there is clear motivation to simplify the analytical solutions and to present the solutions in *tabular* or *graphical* form using simple relations.

The dimensionless quantities defined above for a plane wall can also be used for a *cylinder* or *sphere* by replacing the space variable  $x$  by  $r$  and the half-thickness  $L$  by the outer radius  $r_o$ . Note that the characteristic length in the definition of the Biot number is taken to be the *half-thickness*  $L$  for the plane wall, and the *radius*  $r_o$  for the long cylinder and sphere instead of  $V/A$  used in lumped system analysis.

We mentioned earlier that the terms in the series solutions in Table 4–1 converge rapidly with increasing time, and for  $\tau > 0.2$ , keeping the first term and neglecting all the remaining terms in the series results in an error under 2 percent. We are usually interested in the solution for times with  $\tau > 0.2$ , and thus it is very convenient to express the solution using this **one-term approximation**, given as

$$\text{Plane wall: } \theta_{\text{wall}} = \frac{T(x, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \cos(\lambda_1 x/L), \quad \tau > 0.2 \quad (4-23)$$

$$\text{Cylinder: } \theta_{\text{cyl}} = \frac{T(r, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} J_0(\lambda_1 r/r_o), \quad \tau > 0.2 \quad (4-24)$$

$$\text{Sphere: } \theta_{\text{sph}} = \frac{T(r, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r/r_o)}{\lambda_1 r/r_o}, \quad \tau > 0.2 \quad (4-25)$$

where the constants  $A_1$  and  $\lambda_1$  are functions of the Bi number only, and their values are listed in Table 4–2 against the Bi number for all three geometries. The function  $J_0$  is the zeroth-order Bessel function of the first kind, whose value can be determined from Table 4–3. Noting that  $\cos(0) = J_0(0) = 1$  and the limit of  $(\sin x)/x$  is also 1, these relations simplify to the next ones at the center of a plane wall, cylinder, or sphere:

$$\text{Center of plane wall } (x = 0): \quad \theta_{0, \text{wall}} = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \quad (4-26)$$

$$\text{Center of cylinder } (r = 0): \quad \theta_{0, \text{cyl}} = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \quad (4-27)$$

$$\text{Center of sphere } (r = 0): \quad \theta_{0, \text{sph}} = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \quad (4-28)$$

Comparing the two sets of equations above, we notice that the dimensionless temperatures anywhere in a plane wall, cylinder, and sphere are related to the center temperature by

$$\frac{\theta_{\text{wall}}}{\theta_{0, \text{wall}}} = \cos\left(\frac{\lambda_1 x}{L}\right), \quad \frac{\theta_{\text{cyl}}}{\theta_{0, \text{cyl}}} = J_0\left(\frac{\lambda_1 r}{r_o}\right), \quad \text{and} \quad \frac{\theta_{\text{sph}}}{\theta_{0, \text{sph}}} = \frac{\sin(\lambda_1 r/r_o)}{\lambda_1 r/r_o} \quad (4-29)$$

which shows that time dependence of dimensionless temperature within a given geometry is the same throughout. That is, if the dimensionless center

temperature  $\theta_0$  drops by 20 percent at a specified time, so does the dimensionless temperature  $\theta_0$  anywhere else in the medium at the same time.

Once the Bi number is known, these relations can be used to determine the temperature anywhere in the medium. The determination of the constants  $A_1$  and  $\lambda_1$  usually requires interpolation. For those who prefer reading charts to interpolating, these relations are plotted and the one-term approximation solutions are presented in graphical form, known as the *transient temperature charts*. Note that the charts are sometimes difficult to read, and they are subject to reading errors. Therefore, the relations above should be preferred to the charts.

The transient temperature charts in Figs. 4–17, 4–18, and 4–19 for a large plane wall, long cylinder, and sphere were presented by M. P. Heisler in 1947 and are called **Heisler charts**. They were supplemented in 1961 with transient

heat transfer charts by H. Gröber. There are *three* charts associated with each geometry: the first chart is to determine the temperature  $T_0$  at the *center* of the geometry at a given time  $t$ . The second chart is to determine the temperature at *other locations* at the same time in terms of  $T_0$ . The third chart is to determine the total amount of *heat transfer* up to the time  $t$ . These plots are valid for  $\tau > 0.2$ .

Note that the case  $1/\text{Bi} = k/hL = 0$  corresponds to  $h \rightarrow \infty$ , which corresponds to the case of *specified surface temperature*  $T_\infty$ . That is, the case in which the surfaces of the body are suddenly brought to the temperature  $T_\infty$  at  $t = 0$  and kept at  $T_\infty$  at all times can be handled by setting  $h$  to infinity (Fig. 4-20).

The temperature of the body changes from the initial temperature  $T_i$  to the temperature of the surroundings  $T_\infty$  at the end of the transient heat conduction process. Thus, the *maximum* amount of heat that a body can gain (or lose if  $T_i > T_\infty$ ) is simply the *change* in the *energy content* of the body. That is,

$$Q_{\max} = mc_p(T_\infty - T_i) = \rho V c_p(T_\infty - T_i) \quad (\text{kJ}) \quad (4-30)$$

where  $m$  is the mass,  $V$  is the volume,  $\rho$  is the density, and  $c_p$  is the specific heat of the body. Thus,  $Q_{\max}$  represents the amount of heat transfer for  $t \rightarrow \infty$ . The amount of heat transfer  $Q$  at a finite time  $t$  is obviously less than this maximum, and it can be expressed as the sum of the internal energy changes throughout the entire geometry as

$$Q = \int_V \rho c_p [T(x, t) - T_i] dV \quad (4-31)$$

where  $T(x, t)$  is the temperature distribution in the medium at time  $t$ . Assuming constant properties, the ratio of  $Q/Q_{\max}$  becomes

$$\frac{Q}{Q_{\max}} = \frac{\int_V \rho c_p [T(x, t) - T_i] dV}{\rho c_p (T_\infty - T_i) V} = \frac{1}{V} \int_V (1 - \theta) dV \quad (4-32)$$

Using the appropriate nondimensional temperature relations based on the one-term approximation for the plane wall, cylinder, and sphere, and performing the indicated integrations, we obtain the following relations for the fraction of heat transfer in those geometries:

$$\text{Plane wall: } \left( \frac{Q}{Q_{\max}} \right)_{\text{wall}} = 1 - \theta_{0, \text{wall}} \frac{\sin \lambda_1}{\lambda_1} \quad (4-33)$$

$$\text{Cylinder: } \left( \frac{Q}{Q_{\max}} \right)_{\text{cyl}} = 1 - 2\theta_{0, \text{cyl}} \frac{J_1(\lambda_1)}{\lambda_1} \quad (4-34)$$

$$\text{Sphere: } \left( \frac{Q}{Q_{\max}} \right)_{\text{sph}} = 1 - 3\theta_{0, \text{sph}} \frac{\sin \lambda_1 - \lambda_1 \cos \lambda_1}{\lambda_1^3} \quad (4-35)$$

These  $Q/Q_{\max}$  ratio relations based on the one-term approximation are also plotted in Figures 4-17c, 4-18c, and 4-19c, against the variables Bi and  $h^2 \alpha t / k^2$  for the large plane wall, long cylinder, and sphere, respectively. Note that once the *fraction* of heat transfer  $Q/Q_{\max}$  has been determined from these charts or equations for the given  $t$ , the actual amount of heat transfer by that time can be evaluated by multiplying this fraction by  $Q_{\max}$ . A *negative* sign for  $Q_{\max}$  indicates that the body is *rejecting* heat (Fig. 4-21).

(a) Finite convection coefficient

(b) Infinite convection coefficient

**FIGURE 4-20**

The specified surface temperature corresponds to the case of convection to an environment at  $T_\infty$  with a convection coefficient  $h$  that is *infinite*.

**FIGURE 4-21**

The fraction of total heat transfer  $Q/Q_{\max}$  up to a specified time  $t$  is determined using the Gröber charts.

**FIGURE 4-22**

Fourier number at time  $t$  can be viewed as the ratio of the rate of heat conducted to the rate of heat stored at that time.

The use of the Heisler/Gröber charts and the one-term solutions already discussed is limited to the conditions specified at the beginning of this section: the body is initially at a *uniform* temperature, the temperature of the medium surrounding the body and the convection heat transfer coefficient are *constant* and *uniform*, and there is no *heat generation* in the body.

We discussed the physical significance of the *Biot number* earlier and indicated that it is a measure of the relative magnitudes of the two heat transfer mechanisms: *convection* at the surface and *conduction* through the solid. A *small* value of Bi indicates that the inner resistance of the body to heat conduction is *small* relative to the resistance to convection between the surface and the fluid. As a result, the temperature distribution within the solid becomes fairly uniform, and lumped system analysis becomes applicable. Recall that when  $Bi < 0.1$ , the error in assuming the temperature within the body to be *uniform* is negligible.

To understand the physical significance of the *Fourier number*  $\tau$  (or  $Fo$ ), we express it as (Fig. 4-22)

$$\tau = \frac{\alpha t}{L^2} = \frac{kL^2(1/L)}{\rho c_p L^3/t} \frac{\Delta T}{\Delta T} = \frac{\text{normal area } L^2 \text{ (and thus volume } L^3)}{\text{The rate at which heat is stored in a body of volume } L^3} \quad (4-36)$$

Therefore, the Fourier number is a measure of *heat conducted* through a body relative to *heat stored*. Thus, a large value of the Fourier number indicates faster propagation of heat through a body.

Perhaps you are wondering about what constitutes an infinitely large plate or an infinitely long cylinder. After all, nothing in this world is infinite. A plate whose thickness is small relative to the other dimensions can be modeled as an infinitely large plate, except very near the outer edges. But the edge effects on large bodies are usually negligible, and thus a large plane wall such as the wall of a house can be modeled as an infinitely large wall for heat transfer purposes. Similarly, a long cylinder whose diameter is small relative to its length can be analyzed as an infinitely long cylinder. The use of the transient temperature charts and the one-term solutions is illustrated in Examples 4-3, 4-4, and 4-5.

### EXAMPLE 4-3 Boiling Eggs

An ordinary egg can be approximated as a 5-cm-diameter sphere (Fig. 4-23). The egg is initially at a uniform temperature of 5°C and is dropped into boiling water at 95°C. Taking the convection heat transfer coefficient to be  $h = 1200 \text{ W/m}^2 \cdot \text{K}$ , determine how long it will take for the center of the egg to reach 70°C.

**SOLUTION** An egg is cooked in boiling water. The cooking time of the egg is to be determined.

**Assumptions** 1 The egg is spherical in shape with a radius of  $r_o = 2.5 \text{ cm}$ . 2 Heat conduction in the egg is one-dimensional because of thermal symmetry about the midpoint. 3 The thermal properties of the egg and the heat transfer coefficient are constant. 4 The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The water content of eggs is about 74 percent, and thus the thermal conductivity and diffusivity of eggs can be approximated by those of water at the average temperature of  $(5 + 70)/2 = 37.5^\circ\text{C}$ ;  $k = 0.627 \text{ W/m}\cdot\text{K}$  and  $\alpha = k/\rho c_p = 0.151 \times 10^{-6} \text{ m}^2/\text{s}$  (Table A–9).

**Analysis** Egg white begins to thicken at  $63^\circ\text{C}$  and turns solid at  $65^\circ\text{C}$ . The yolk begins to thicken at  $65^\circ\text{C}$  and sets at  $70^\circ\text{C}$ . The whole egg sets at temperatures above  $70^\circ\text{C}$ . Therefore, the egg in this case will qualify as hard boiled. The temperature within the egg varies with radial distance as well as time, and the temperature at a specified location at a given time can be determined from the Heisler charts or the one-term solutions. Here we use the latter to demonstrate their use. The Biot number for this problem is

$$\text{Bi} = \frac{hr_o}{k} = \frac{(1200 \text{ W/m}^2\cdot\text{K})(0.025 \text{ m})}{0.627 \text{ W/m}\cdot\text{K}} = 47.8$$

which is much greater than 0.1, and thus the lumped system analysis is not applicable. The coefficients  $\lambda_1$  and  $A_1$  for a sphere corresponding to this Bi are, from Table 4–2,

$$\lambda_1 = 3.0754, \quad A_1 = 1.9958$$

Substituting these and other values into Eq. 4–28 and solving for  $\tau$  gives

$$\frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \longrightarrow \frac{70 - 95}{5 - 95} = 1.9958 e^{-(3.0754)^2 \tau} \longrightarrow \tau = 0.209$$

which is greater than 0.2, and thus the one-term solution is applicable with an error of less than 2 percent. Then the cooking time is determined from the definition of the Fourier number to be

$$t = \frac{\pi r_o^2}{\alpha} = \frac{(0.209)(0.025 \text{ m})^2}{0.151 \times 10^{-6} \text{ m}^2/\text{s}} = 865 \text{ s} \approx \mathbf{14.4 \text{ min}}$$

Therefore, it will take about 15 min for the center of the egg to be heated from  $5^\circ\text{C}$  to  $70^\circ\text{C}$ .

**Discussion** Note that the Biot number in lumped system analysis was defined differently as  $\text{Bi} = hL_c/k = h(r_o/3)/k$ . However, either definition can be used in determining the applicability of the lumped system analysis unless  $\text{Bi} \approx 0.1$ .

Also note that the cooking time depends on many parameters such as the size of the egg, its temperature before cooking, the boiling temperature of water (and thus altitude), the heat transfer coefficient (and thus the level of bubble motion during boiling). Therefore, there is a considerable amount of science or a good amount of experience behind boiling eggs to the correct amount of doneness.

#### EXAMPLE 4–4 Heating of Brass Plates in an Oven

In a production facility, large brass plates of 4-cm thickness that are initially at a uniform temperature of  $20^\circ\text{C}$  are heated by passing them through an oven that is maintained at  $500^\circ\text{C}$  (Fig. 4–24). The plates remain in the oven for a period of 7 min. Taking the combined convection and radiation heat transfer coefficient to be  $h = 120 \text{ W/m}^2\cdot\text{K}$ , determine the surface temperature of the plates when they come out of the oven.

**FIGURE 4–23**  
Schematic for Example 4–3.

**FIGURE 4–24**  
Schematic for Example 4–4.

**SOLUTION** Large brass plates are heated in an oven. The surface temperature of the plates leaving the oven is to be determined.

**Assumptions** 1 Heat conduction in the plate is one-dimensional since the plate is large relative to its thickness and there is thermal symmetry about the center plane. 2 The thermal properties of the plate and the heat transfer coefficient are constant. 3 The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The properties of brass at room temperature are  $k = 110 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 380 \text{ J/kg}\cdot\text{K}$ , and  $\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$  (Table A-3). More accurate results are obtained by using properties at average temperature.

**Analysis** The temperature at a specified location at a given time can be determined from the Heisler charts or one-term solutions. Here we use the charts to demonstrate their use. Noting that the half-thickness of the plate is  $L = 0.02 \text{ m}$ , from Fig. 4-17 we have

$$\left. \begin{aligned} \frac{1}{\text{Bi}} &= \frac{k}{hL} = \frac{110 \text{ W/m}\cdot\text{K}}{(120 \text{ W/m}^2\cdot\text{K})(0.02 \text{ m})} = 45.8 \\ \tau &= \frac{\alpha t}{L^2} = \frac{(33.9 \times 10^{-6} \text{ m}^2/\text{s})(7 \times 60 \text{ s})}{(0.02 \text{ m})^2} = 35.6 \end{aligned} \right\} \frac{T_0 - T_\infty}{T_i - T_\infty} = 0.46$$

Also,

$$\left. \begin{aligned} \frac{1}{\text{Bi}} &= \frac{k}{hL} = 45.8 \\ \frac{x}{L} &= \frac{L}{L} = 1 \end{aligned} \right\} \frac{T - T_\infty}{T_0 - T_\infty} = 0.99$$

Therefore,

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{T - T_\infty}{T_0 - T_\infty} \frac{T_0 - T_\infty}{T_i - T_\infty} = 0.46 \times 0.99 = 0.455$$

and

$$T = T_\infty + 0.455(T_i - T_\infty) = 500 + 0.455(20 - 500) = 282^\circ\text{C}$$

Therefore, the surface temperature of the plates will be  $282^\circ\text{C}$  when they leave the oven.

**Discussion** We notice that the Biot number in this case is  $\text{Bi} = 1/45.8 = 0.022$ , which is much less than 0.1. Therefore, we expect the lumped system analysis to be applicable. This is also evident from  $(T - T_\infty)/(T_0 - T_\infty) = 0.99$ , which indicates that the temperatures at the center and the surface of the plate relative to the surrounding temperature are within 1 percent of each other. Noting that the error involved in reading the Heisler charts is typically a few percent, the lumped system analysis in this case may yield just as accurate results with less effort.

The heat transfer surface area of the plate is  $2A$ , where  $A$  is the face area of the plate (the plate transfers heat through both of its surfaces), and the volume of the plate is  $V = (2L)A$ , where  $L$  is the half-thickness of the plate. The exponent  $b$  used in the lumped system analysis is

$$\begin{aligned} b &= \frac{hA_s}{\rho c_p V} = \frac{h(2A)}{\rho c_p (2LA)} = \frac{h}{\rho c_p L} \\ &= \frac{120 \text{ W/m}^2\cdot\text{K}}{(8530 \text{ kg/m}^3)(380 \text{ J/kg}\cdot\text{K})(0.02 \text{ m})} = 0.00185 \text{ s}^{-1} \end{aligned}$$

Then the temperature of the plate at  $t = 7 \text{ min} = 420 \text{ s}$  is determined from

$$\frac{T(t) - T_{\infty}}{T_i - T_{\infty}} = e^{-bt} \longrightarrow \frac{T(t) - 500}{20 - 500} = e^{-(0.00185 \text{ s}^{-1})(420 \text{ s})}$$

It yields

$$T(t) = 279^\circ\text{C}$$

which is practically identical to the result obtained above using the Heisler charts. Therefore, we can use lumped system analysis with confidence when the Biot number is sufficiently small.

### EXAMPLE 4–5 Cooling of a Long Stainless Steel Cylindrical Shaft

A long 20-cm-diameter cylindrical shaft made of stainless steel 304 comes out of an oven at a uniform temperature of  $600^\circ\text{C}$  (Fig. 4–25). The shaft is then allowed to cool slowly in an environment chamber at  $200^\circ\text{C}$  with an average heat transfer coefficient of  $h = 80 \text{ W/m}^2\cdot\text{K}$ . Determine the temperature at the center of the shaft 45 min after the start of the cooling process. Also, determine the heat transfer per unit length of the shaft during this time period.

**SOLUTION** A long cylindrical shaft is allowed to cool slowly. The center temperature and the heat transfer per unit length are to be determined.

**Assumptions** 1 Heat conduction in the shaft is one-dimensional since it is long and it has thermal symmetry about the centerline. 2 The thermal properties of the shaft and the heat transfer coefficient are constant. 3 The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The properties of stainless steel 304 at room temperature are  $k = 14.9 \text{ W/m}\cdot\text{K}$ ,  $\rho = 7900 \text{ kg/m}^3$ ,  $c_p = 477 \text{ J/kg}\cdot\text{K}$ , and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$  (Table A–3). More accurate results can be obtained by using properties at average temperature.

**Analysis** The temperature within the shaft may vary with the radial distance  $r$  as well as time, and the temperature at a specified location at a given time can be determined from the Heisler charts. Noting that the radius of the shaft is  $r_o = 0.1 \text{ m}$ , from Fig. 4–18a we have

$$\left. \begin{aligned} \frac{1}{Bi} &= \frac{k}{hr_o} = \frac{14.9 \text{ W/m}\cdot\text{K}}{(80 \text{ W/m}^2\cdot\text{K})(0.1 \text{ m})} = 1.86 \\ \tau &= \frac{\alpha t}{r_o^2} = \frac{(3.95 \times 10^{-6} \text{ m}^2/\text{s})(45 \times 60 \text{ s})}{(0.1 \text{ m})^2} = 1.07 \end{aligned} \right\} \frac{T_0 - T_{\infty}}{T_i - T_{\infty}} = 0.40$$

and

$$T_0 = T_{\infty} + 0.4(T_i - T_{\infty}) = 200 + 0.4(600 - 200) = 360^\circ\text{C}$$

Therefore, the center temperature of the shaft drops from  $600^\circ\text{C}$  to  $360^\circ\text{C}$  in 45 min.

FIGURE 4–25

Schematic for Example 4–5.

To determine the actual heat transfer, we first need to calculate the maximum heat that can be transferred from the cylinder, which is the sensible energy of the cylinder relative to its environment. Taking  $L = 1 \text{ m}$ ,

$$\begin{aligned} m &= \rho V = \rho \pi r_o^2 L = (7900 \text{ kg/m}^3) \pi (0.1 \text{ m})^2 (1 \text{ m}) = 248.2 \text{ kg} \\ Q_{\max} &= mc_p(T_i - T_\infty) = (248.2 \text{ kg})(0.477 \text{ kJ/kg}\cdot\text{K})(600 - 200)^\circ\text{C} \\ &= 47,350 \text{ kJ} \end{aligned}$$

The dimensionless heat transfer ratio is determined from Fig. 4–18c for a long cylinder to be

$$\left. \begin{aligned} \text{Bi} &= \frac{1}{1/\text{Bi}} = \frac{1}{1.86} = 0.537 \\ \frac{h^2 \alpha t}{k^2} &= \text{Bi}^2 \tau = (0.537)^2 (1.07) = 0.309 \end{aligned} \right\} \frac{Q}{Q_{\max}} = 0.62$$

Therefore,

$$Q = 0.62 Q_{\max} = 0.62 \times (47,350 \text{ kJ}) = \mathbf{29,360 \text{ kJ}}$$

which is the total heat transfer from the shaft during the first 45 min of the cooling.

**Alternative solution** We could also solve this problem using the one-term solution relation instead of the transient charts. First we find the Biot number

$$\text{Bi} = \frac{hr_o}{k} = \frac{(80 \text{ W/m}^2\cdot\text{K})(0.1 \text{ m})}{14.9 \text{ W/m}\cdot\text{K}} = 0.537$$

The coefficients  $\lambda_1$  and  $A_1$  for a cylinder corresponding to this Bi are determined from Table 4–2 to be

$$\lambda_1 = 0.970, \quad A_1 = 1.122$$

Substituting these values into Eq. 4–27 gives

$$\theta_0 = \frac{T_0 - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} = 1.122 e^{-(0.970)^2 (1.07)} = 0.41$$

and thus

$$T_0 = T_\infty + 0.41(T_i - T_\infty) = 200 + 0.41(600 - 200) = \mathbf{364^\circ\text{C}}$$

The value of  $J_1(\lambda_1)$  for  $\lambda_1 = 0.970$  is determined from Table 4–3 to be 0.430. Then the fractional heat transfer is determined from Eq. 4–34 to be

$$\frac{Q}{Q_{\max}} = 1 - 2\theta_0 \frac{J_1(\lambda_1)}{\lambda_1} = 1 - 2 \times 0.41 \frac{0.430}{0.970} = 0.636$$

and thus

$$Q = 0.636 Q_{\max} = 0.636 \times (47,350 \text{ kJ}) = \mathbf{30,120 \text{ kJ}}$$

**Discussion** The slight difference between the two results is due to the reading error of the charts.

## 4-3 ▪ TRANSIENT HEAT CONDUCTION IN SEMI-INFINITE SOLIDS

A semi-infinite solid is an idealized body that has a *single plane surface* and extends to infinity in all directions, as shown in Figure 4-26. This idealized body is used to indicate that the temperature change in the part of the body in which we are interested (the region close to the surface) is due to the thermal conditions on a single surface. The earth, for example, can be considered to be a semi-infinite medium in determining the variation of temperature near its surface. Also, a thick wall can be modeled as a semi-infinite medium if all we are interested in is the variation of temperature in the region near one of the surfaces, and the other surface is too far to have any impact on the region of interest during the time of observation. The temperature in the core region of the wall remains unchanged in this case.

For short periods of time, most bodies can be modeled as semi-infinite solids since heat does not have sufficient time to penetrate deep into the body, and the thickness of the body does not enter into the heat transfer analysis. A steel piece of any shape, for example, can be treated as a semi-infinite solid when it is quenched rapidly to harden its surface. A body whose surface is heated by a laser pulse can be treated the same way.

Consider a semi-infinite solid with constant thermophysical properties, no internal heat generation, uniform thermal conditions on its exposed surface, and initially a uniform temperature of  $T_i$  throughout. Heat transfer in this case occurs only in the direction normal to the surface (the  $x$  direction), and thus it is one-dimensional. Differential equations are independent of the boundary or initial conditions, and thus Eq. 4-10a for one-dimensional transient conduction in Cartesian coordinates applies. The depth of the solid is large ( $x \rightarrow \infty$ ) compared to the depth that heat can penetrate, and these phenomena can be expressed mathematically as a boundary condition as  $T(x \rightarrow \infty, t) = T_i$ .

Heat conduction in a semi-infinite solid is governed by the thermal conditions imposed on the exposed surface, and thus the solution depends strongly on the boundary condition at  $x = 0$ . Below we present a detailed analytical solution for the case of constant temperature  $T_s$  on the surface, and give the results for other more complicated boundary conditions. When the surface temperature is changed to  $T_s$  at  $t = 0$  and held constant at that value at all times, the formulation of the problem can be expressed as

$$\text{Differential equation: } \frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (4-37a)$$

$$\text{Boundary conditions: } T(0, t) = T_s \quad \text{and} \quad T(x \rightarrow \infty, t) = T_i \quad (4-37b)$$

$$\text{Initial condition: } T(x, 0) = T_i \quad (4-37c)$$

The separation of variables technique does not work in this case since the medium is infinite. But another clever approach that converts the partial differential equation into an ordinary differential equation by combining the two independent variables  $x$  and  $t$  into a single variable  $\eta$ , called the **similarity variable**, works well. For transient conduction in a semi-infinite medium, it is defined as

$$\text{Similarity variable: } \eta = \frac{x}{\sqrt{4\alpha t}} \quad (4-38)$$

**FIGURE 4-26**

Schematic of a semi-infinite body.

$$\begin{aligned}\frac{\partial^2 T}{\partial x^2} &= \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad \text{and} \quad \eta = \frac{x}{\sqrt{4\alpha t}} \\ \frac{\partial T}{\partial t} &= \frac{dT}{d\eta} \frac{\partial \eta}{\partial t} = \frac{-x}{2t\sqrt{4\alpha t}} \frac{dT}{d\eta} \\ \frac{\partial T}{\partial x} &= \frac{dT}{d\eta} \frac{\partial \eta}{\partial x} = \frac{1}{\sqrt{4\alpha t}} \frac{dT}{d\eta} \\ \frac{\partial^2 T}{\partial x^2} &= \frac{d}{d\eta} \left( \frac{\partial T}{\partial x} \right) \frac{\partial \eta}{\partial x} = \frac{1}{4\alpha t} \frac{d^2 T}{d\eta^2}\end{aligned}$$

**FIGURE 4-27**

Transformation of variables in the derivatives of the heat conduction equation by the use of chain rule.

Assuming  $T = T(\eta)$  (to be verified) and using the chain rule, all derivatives in the heat conduction equation can be transformed into the new variable, as shown in Fig. 4-27. Noting that  $\eta = 0$  at  $x = 0$  and  $\eta \rightarrow \infty$  as  $x \rightarrow \infty$  (and also at  $t = 0$ ) and substituting into Eqs. 4-37 give, after simplification,

$$\frac{d^2 T}{d\eta^2} = -2\eta \frac{dT}{d\eta} \quad (4-39a)$$

$$T(0) = T_s \quad \text{and} \quad T(\eta \rightarrow \infty) = T_i \quad (4-39b)$$

Note that the second boundary condition and the initial condition result in the same boundary condition. Both the transformed equation and the boundary conditions depend on  $\eta$  only and are independent of  $x$  and  $t$ . Therefore, transformation is successful, and  $\eta$  is indeed a similarity variable.

To solve the 2nd order ordinary differential equation in Eqs. 4-39, we define a new variable  $w$  as  $w = dT/d\eta$ . This reduces Eq. 4-39a into a first order differential equation than can be solved by separating variables,

$$\frac{dw}{d\eta} = -2\eta w \rightarrow \frac{dw}{w} = -2\eta d\eta \rightarrow \ln w = -\eta^2 + C_0 \rightarrow w = C_1 e^{-\eta^2}$$

where  $C_1 = \ln C_0$ . Back substituting  $w = dT/d\eta$  and integrating again,

$$T = C_1 \int_0^\eta e^{-u^2} du + C_2 \quad (4-40)$$

where  $u$  is a dummy integration variable. The boundary condition at  $\eta = 0$  gives  $C_2 = T_s$ , and the one for  $\eta \rightarrow \infty$  gives

$$T_i = C_1 \int_0^\infty e^{-u^2} du + C_2 = C_1 \frac{\sqrt{\pi}}{2} + T_s \rightarrow C_1 = \frac{2(T_i - T_s)}{\sqrt{\pi}} \quad (4-41)$$

Substituting the  $C_1$  and  $C_2$  expressions into Eq. 4-40 and rearranging, the variation of temperature becomes

$$\frac{T - T_s}{T_i - T_s} = \frac{2}{\sqrt{\pi}} \int_0^\eta e^{-u^2} du = \text{erf}(\eta) = 1 - \text{erfc}(\eta) \quad (4-42)$$

where the mathematical functionsrom

$$\text{erf}(\eta) = \frac{2}{\sqrt{\pi}} \int_0^\eta e^{-u^2} du \quad \text{and} \quad \text{erfc}(\eta) = 1 - \text{erf}(\eta) = 1 - \frac{2}{\sqrt{\pi}} \int_0^\eta e^{-u^2} du \quad (4-43)$$

are called the **error function** and the **complementary error function**, respectively, of argument  $\eta$  (Fig. 4-28). Despite its simple appearance, the integral in the definition of the error function cannot be performed analytically. Therefore, the function  $\text{erfc}(\eta)$  is evaluated numerically for different values of  $\eta$ , and the results are listed in Table 4-4.

**FIGURE 4-28**

Error function is a standard mathematical function, just like the sinus and tangent functions, whose value varies between 0 and 1.

**TABLE 4-4**

The complementary error function

Knowing the temperature distribution, the heat flux at the surface can be determined from the Fourier's law to be

$$\dot{q}_s = -k \frac{\partial T}{\partial x} \Big|_{x=0} = -k \frac{dT}{d\eta} \frac{\partial \eta}{\partial x} \Big|_{\eta=0} = -k C_1 e^{-\eta^2} \frac{1}{\sqrt{4\alpha t}} \Big|_{\eta=0} = \frac{k(T_s - T_i)}{\sqrt{\pi \alpha t}} \quad (4-44)$$

The solutions in Eqs. 4-42 and 4-44 correspond to the case when the temperature of the exposed surface of the medium is suddenly raised (or lowered) to  $T_s$  at  $t = 0$  and is maintained at that value at all times. The specified surface temperature case is closely approximated in practice when condensation or boiling takes place on the surface. Using a similar approach or the Laplace transform technique, analytical solutions can be obtained for other boundary conditions on the surface, with the following results.

**Case 1: Specified Surface Temperature,  $T_s = \text{constant}$  (Fig. 4-29).**

$$\frac{T(x, t) - T_i}{T_s - T_i} = \text{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right) \quad \text{and} \quad \dot{q}_s(t) = \frac{k(T_s - T_i)}{\sqrt{\pi \alpha t}} \quad (4-45)$$

**Case 2: Specified Surface Heat Flux,  $\dot{q}_s = \text{constant}$ .**

$$T(x, t) - T_i = \frac{\dot{q}_s}{k} \left[ \sqrt{\frac{4\alpha t}{\pi}} \exp \left( -\frac{x^2}{4\alpha t} \right) - x \text{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right) \right] \quad (4-46)$$

**FIGURE 4-29**

Dimensionless temperature distribution for transient conduction in a semi-infinite solid whose surface is maintained at a constant temperature  $T_s$ .

**Case 3: Convection on the Surface,  $\dot{q}_s(t) = h[T_\infty - T(0, t)]$ .**

$$\frac{T(x, t) - T_i}{T_\infty - T_i} = \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k} + \frac{h^2\alpha t}{k^2}\right) \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k}\right) \quad (4-47)$$

**Case 4: Energy Pulse at Surface,  $e_s = \text{constant}$ .**

Energy in the amount of  $e_s$  per unit surface area (in J/m<sup>2</sup>) is supplied to the semi-infinite body instantaneously at time  $t = 0$  (by a laser pulse, for example), and the entire energy is assumed to enter the body, with no heat loss from the surface.

$$T(x, t) - T_i = \frac{e_s}{k\sqrt{\pi t/\alpha}} \exp\left(-\frac{x^2}{4\alpha t}\right) \quad (4-48)$$

Note that Cases 1 and 3 are closely related. In Case 1, the surface  $x = 0$  is brought to a temperature  $T_s$  at time  $t = 0$ , and kept at that value at all times. In Case 3, the surface is exposed to convection by a fluid at a constant temperature  $T_\infty$  with a heat transfer coefficient  $h$ .

The solutions for all four cases are plotted in Fig. 4–30 for a representative case using a large cast iron block initially at 0°C throughout. In Case 1, the surface temperature remains constant at the specified value of  $T_s$ , and temperature increases gradually within the medium as heat penetrates deeper into the solid. Note that during initial periods only a thin slice near the surface is affected by heat transfer. Also, the temperature gradient at the surface and thus the rate of heat transfer into the solid decreases with time. In Case 2, heat is continually supplied to the solid, and thus the temperature within the solid, including the surface, increases with time. This is also the case with convection (Case 3), except that the surrounding fluid temperature  $T_\infty$  is the highest temperature that the solid body can rise to. In Case 4, the surface is subjected to an instant burst of heat supply at time  $t = 0$ , such as heating by a laser pulse, and then the surface is covered with insulation. The result is an instant rise in surface temperature, followed by a temperature drop as heat is conducted deeper into the solid. Note that the temperature profile is always normal to the surface at all times. (Why?)

The variation of temperature with position and time in a semi-infinite solid subjected to convection heat transfer is plotted in Fig. 4–31 for the nondimensionalized temperature against the dimensionless similarity variable  $\eta = x/\sqrt{4\alpha t}$  for various values of the parameter  $h\sqrt{\alpha t}/k$ . Although the graphical solution given in Fig. 4–31 is simply a plot of the exact analytical solution, it is subject to reading errors, and thus is of limited accuracy compared to the analytical solution. Also, the values on the vertical axis of Fig. 4–31 correspond to  $x = 0$ , and thus represent the surface temperature. The curve  $h\sqrt{\alpha t}/k = \infty$  corresponds to  $h \rightarrow \infty$ , which corresponds to the case of *specified temperature  $T_\infty$*  at the surface at  $x = 0$ . That is, the case in which the surface of the semi-infinite body is suddenly brought to temperature  $T_\infty$  at  $t = 0$  and kept at  $T_\infty$  at all times can be handled by setting  $h$  to infinity. For a *finite* heat transfer coefficient  $h$ , the surface temperature approaches the fluid temperature  $T_\infty$  as the time  $t$  approaches infinity.

**FIGURE 4-30**  
Variations of temperature with position and time in a large cast iron block ( $\alpha = 2.31 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $k = 80.2 \text{ W/m}\cdot\text{K}$ ) initially at  $0^\circ\text{C}$  under different thermal conditions on the surface.

## Contact of Two Semi-Infinite Solids

When two large bodies  $A$  and  $B$ , initially at uniform temperatures  $T_{A,i}$  and  $T_{B,i}$  are brought into contact, they instantly achieve temperature equality at the contact surface (temperature equality is achieved over the entire surface if the contact resistance is negligible). If the two bodies are of the same material with constant properties, thermal symmetry requires the contact surface temperature to be the arithmetic average,  $T_s = (T_{A,i} + T_{B,i})/2$  and to remain constant at that value at all times.

**FIGURE 4-31**

Variation of temperature with position and time in a semi-infinite solid initially at temperature  $T_i$  subjected to convection to an environment at  $T_\infty$  with a convection heat transfer coefficient  $h$  (plotted using EES).

If the bodies are of different materials, they still achieve a temperature equality, but the surface temperature  $T_s$  in this case will be different than the arithmetic average. Noting that both bodies can be treated as semi-infinite solids with the same specified surface temperature, the energy balance on the contact surface gives, from Eq. 4-45,

$$\dot{q}_{s,A} = \dot{q}_{s,B} \rightarrow -\frac{k_A(T_s - T_{A,i})}{\sqrt{\pi\alpha_A t}} = \frac{k_B(T_s - T_{B,i})}{\sqrt{\pi\alpha_B t}} \rightarrow \frac{T_{A,i} - T_s}{T_s - T_{B,i}} = \sqrt{\frac{(k\rho c_p)_B}{(k\rho c_p)_A}}$$

Then  $T_s$  is determined to be (Fig. 4-32)

$$T_s = \frac{\sqrt{(k\rho c_p)_A}T_{A,i} + \sqrt{(k\rho c_p)_B}T_{B,i}}{\sqrt{(k\rho c_p)_A} + \sqrt{(k\rho c_p)_B}} \quad (4-49)$$

Therefore, the interface temperature of two bodies brought into contact is dominated by the body with the larger  $k\rho c_p$ . This also explains why a metal at room temperature feels colder than wood at the same temperature. At room temperature, the  $\sqrt{k\rho c_p}$  value is 24 kJ/m<sup>2</sup>·K for aluminum, 0.38 kJ/m<sup>2</sup>·K for wood, and 1.1 kJ/m<sup>2</sup>·K for the human flesh. Using Eq. 4-49, it can be shown that when a person with a skin temperature of 35°C touches an aluminum block and then a wood block both at 15°C, the contact surface temperature will be 15.9°C in the case of aluminum and 30°C in the case of wood.

**FIGURE 4-32**

Contact of two semi-infinite solids of different initial temperatures.

**EXAMPLE 4–6** Minimum Burial Depth of Water Pipes to Avoid Freezing

In areas where the air temperature remains below 0°C for prolonged periods of time, the freezing of water in underground pipes is a major concern. Fortunately, the soil remains relatively warm during those periods, and it takes weeks for the subfreezing temperatures to reach the water mains in the ground. Thus, the soil effectively serves as an insulation to protect the water from sub-freezing temperatures in winter.

The ground at a particular location is covered with snow pack at  $-10^{\circ}\text{C}$  for a continuous period of three months, and the average soil properties at that location are  $k = 0.4 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$  (Fig. 4–33). Assuming an initial uniform temperature of  $15^{\circ}\text{C}$  for the ground, determine the minimum burial depth to prevent the water pipes from freezing.

**SOLUTION** The water pipes are buried in the ground to prevent freezing. The minimum burial depth at a particular location is to be determined.

**Assumptions** 1 The temperature in the soil is affected by the thermal conditions at one surface only, and thus the soil can be considered to be a semi-infinite medium. 2 The thermal properties of the soil are constant.

**Properties** The properties of the soil are as given in the problem statement.

**Analysis** The temperature of the soil surrounding the pipes will be  $0^{\circ}\text{C}$  after three months in the case of minimum burial depth. Therefore, from Fig. 4–31, we have

$$\left. \begin{aligned} \frac{h\sqrt{\alpha t}}{k} &= \infty \quad (\text{since } h \rightarrow \infty) \\ \frac{T(x, t) - T_i}{T_\infty - T_i} &= \frac{0 - 15}{-10 - 15} = 0.6 \end{aligned} \right\} \eta = \frac{x}{2\sqrt{\alpha t}} = 0.36$$

We note that

$$t = (90 \text{ days})(24 \text{ h/day})(3600 \text{ s/h}) = 7.78 \times 10^6 \text{ s}$$

and thus

$$x = 2\eta\sqrt{\alpha t} = 2 \times 0.36\sqrt{(0.15 \times 10^{-6} \text{ m}^2/\text{s})(7.78 \times 10^6 \text{ s})} = \mathbf{0.78 \text{ m}}$$

Therefore, the water pipes must be buried to a depth of at least 78 cm to avoid freezing under the specified harsh winter conditions.

**ALTERNATIVE SOLUTION** The solution of this problem could also be determined from Eq. 4–45:

$$\frac{T(x, t) - T_i}{T_s - T_i} = \operatorname{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right) \longrightarrow \frac{0 - 15}{-10 - 15} = \operatorname{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right) = 0.60$$

The argument that corresponds to this value of the complementary error function is determined from Table 4–4 to be  $\eta = 0.37$ . Therefore,

$$x = 2\eta\sqrt{\alpha t} = 2 \times 0.37\sqrt{(0.15 \times 10^{-6} \text{ m}^2/\text{s})(7.78 \times 10^6 \text{ s})} = \mathbf{0.80 \text{ m}}$$

Again, the slight difference is due to the reading error of the chart.

**FIGURE 4–33**

Schematic for Example 4–6.

**FIGURE 4–34**

Schematic for Example 4–7.

**FIGURE 4–35**Variation of temperature within the wood and aluminum blocks at  $t = 20 \text{ min}$ .**EXAMPLE 4–7 Surface Temperature Rise of Heated Blocks**

A thick black-painted wood block at  $20^\circ\text{C}$  is subjected to constant solar heat flux of  $1250 \text{ W/m}^2$  (Fig. 4–34). Determine the exposed surface temperature of the block after 20 minutes. What would your answer be if the block were made of aluminum?

**SOLUTION** A wood block is subjected to solar heat flux. The surface temperature of the block is to be determined, and to be compared to the value for an aluminum block.

**Assumptions** 1 All incident solar radiation is absorbed by the block. 2 Heat loss from the block is disregarded (and thus the result obtained is the maximum temperature). 3 The block is sufficiently thick to be treated as a semi-infinite solid, and the properties of the block are constant.

**Properties** Thermal conductivity and diffusivity values at room temperature are  $k = 0.159 \text{ W/m}\cdot\text{K}$  and  $\alpha = k/\rho c_p = 1.75 \times 10^{-7} \text{ m}^2/\text{s}$  for hardwoods (Table A–5) and  $k = 237 \text{ W/m}\cdot\text{K}$  and  $\alpha = 9.71 \times 10^{-5} \text{ m}^2/\text{s}$  for pure aluminum (Table A–3).

**Analysis** This is a transient conduction problem in a semi-infinite medium subjected to constant surface heat flux, and the surface temperature can be expressed from Eq. 4–46 as

$$T_s = T(0, t) = T_i + \frac{\dot{q}_s}{k} \sqrt{\frac{4\alpha t}{\pi}}$$

Substituting the given values, the surface temperatures for both the wood and aluminum blocks are determined to be

$$T_{s, \text{wood}} = 20^\circ\text{C} + \frac{1250 \text{ W/m}^2}{0.159 \text{ W/m}\cdot\text{K}} \sqrt{\frac{4(1.75 \times 10^{-7} \text{ m}^2/\text{s})(20 \times 60\text{s})}{\pi}} = 149^\circ\text{C}$$

$$T_{s, \text{Al}} = 20^\circ\text{C} + \frac{1250 \text{ W/m}^2}{237 \text{ W/m}\cdot\text{K}} \sqrt{\frac{4(9.71 \times 10^{-5} \text{ m}^2/\text{s})(20 \times 60\text{s})}{\pi}} = 22.0^\circ\text{C}$$

Note that thermal energy supplied to the wood accumulates near the surface because of the low conductivity and diffusivity of wood, causing the surface temperature to rise to high values. Metals, on the other hand, conduct the heat they receive to inner parts of the block because of their high conductivity and diffusivity, resulting in minimal temperature rise at the surface. In reality, both temperatures will be lower because of heat losses.

**Discussion** The temperature profiles for both wood and aluminum blocks at  $t = 20 \text{ min}$  are evaluated and plotted in Fig. 4–35 using EES. At a depth of  $x = 0.044 \text{ m}$  the temperature in both blocks is  $21.8^\circ\text{C}$ . At a depth of  $0.08 \text{ m}$ , the temperatures become  $20.0^\circ\text{C}$  for wood and  $21.6^\circ\text{C}$  for aluminum block, which confirms that heat penetrates faster and further in metals compared to nonmetals.

## 4–4 ■ TRANSIENT HEAT CONDUCTION IN MULTIDIMENSIONAL SYSTEMS

The transient temperature charts and analytical solutions presented earlier can be used to determine the temperature distribution and heat transfer in *one-dimensional* heat conduction problems associated with a large plane wall, a

long cylinder, a sphere, and a semi-infinite medium. Using a superposition approach called the **product solution**, these charts and solutions can also be used to construct solutions for the *two-dimensional* transient heat conduction problems encountered in geometries such as a short cylinder, a long rectangular bar, or a semi-infinite cylinder or plate, and even *three-dimensional* problems associated with geometries such as a rectangular prism or a semi-infinite rectangular bar, provided that *all* surfaces of the solid are subjected to convection to the *same* fluid at temperature  $T_\infty$ , with the *same* heat transfer coefficient  $h$ , and the body involves no heat generation (Fig. 4–36). The solution in such multidimensional geometries can be expressed as the *product* of the solutions for the one-dimensional geometries whose intersection is the multidimensional geometry.

Consider a *short cylinder* of height  $a$  and radius  $r_o$  initially at a uniform temperature  $T_i$ . There is no heat generation in the cylinder. At time  $t = 0$ , the cylinder is subjected to convection from all surfaces to a medium at temperature  $T_\infty$  with a heat transfer coefficient  $h$ . The temperature within the cylinder will change with  $x$  as well as  $r$  and time  $t$  since heat transfer occurs from the top and bottom of the cylinder as well as its side surfaces. That is,  $T = T(r, x, t)$  and thus this is a two-dimensional transient heat conduction problem. When the properties are assumed to be constant, it can be shown that the solution of this two-dimensional problem can be expressed as

$$\left( \frac{T(r, x, t) - T_\infty}{T_i - T_\infty} \right)_{\text{cylinder}}^{\text{short}} = \left( \frac{T(x, t) - T_\infty}{T_i - T_\infty} \right)_{\text{wall}}^{\text{plane}} \left( \frac{T(r, t) - T_\infty}{T_i - T_\infty} \right)_{\text{cylinder}}^{\text{infinite}} \quad (4-50)$$

That is, the solution for the two-dimensional short cylinder of height  $a$  and radius  $r_o$  is equal to the *product* of the nondimensionalized solutions for the one-dimensional plane wall of thickness  $a$  and the long cylinder of radius  $r_o$ , which are the two geometries whose intersection is the short cylinder, as shown in Fig. 4–37. We generalize this as follows: *the solution for a multidimensional geometry is the product of the solutions of the one-dimensional geometries whose intersection is the multidimensional body*.

For convenience, the one-dimensional solutions are denoted by

$$\begin{aligned} \theta_{\text{wall}}(x, t) &= \left( \frac{T(x, t) - T_\infty}{T_i - T_\infty} \right)_{\text{wall}}^{\text{plane}} \\ \theta_{\text{cyl}}(r, t) &= \left( \frac{T(r, t) - T_\infty}{T_i - T_\infty} \right)_{\text{cylinder}}^{\text{infinite}} \\ \theta_{\text{semi-inf}}(x, t) &= \left( \frac{T(x, t) - T_\infty}{T_i - T_\infty} \right)_{\text{solid}}^{\text{semi infinite}} \end{aligned} \quad (4-51)$$

For example, the solution for a long solid bar whose cross section is an  $a \times b$  rectangle is the intersection of the two infinite plane walls of thicknesses  $a$  and  $b$ , as shown in Fig. 4–38, and thus the transient temperature distribution for this rectangular bar can be expressed as

$$\left( \frac{T(x, y, t) - T_\infty}{T_i - T_\infty} \right)_{\text{bar}}^{\text{rectangular}} = \theta_{\text{wall}}(x, t) \theta_{\text{wall}}(y, t) \quad (4-52)$$

The proper forms of the product solutions for some other geometries are given in Table 4–5. It is important to note that the  $x$ -coordinate is measured from the

(a) Long cylinder

(b) Short cylinder (two-dimensional)

**FIGURE 4–36**

The temperature in a short cylinder exposed to convection from all surfaces varies in both the radial and axial directions, and thus heat is transferred in both directions.

**FIGURE 4–37**

A short cylinder of radius  $r_o$  and height  $a$  is the *intersection* of a long cylinder of radius  $r_o$  and a plane wall of thickness  $a$ .

surface in a semi-infinite solid, and from the *midplane* in a plane wall. The radial distance  $r$  is always measured from the centerline.

Note that the solution of a *two-dimensional* problem involves the product of *two* one-dimensional solutions, whereas the solution of a *three-dimensional* problem involves the product of *three* one-dimensional solutions.

A modified form of the product solution can also be used to determine the total transient heat transfer to or from a multidimensional geometry by using the one-dimensional values, as shown by L. S. Langston in 1982. The transient heat transfer for a two-dimensional geometry formed by the intersection of two one-dimensional geometries 1 and 2 is

$$\left(\frac{Q}{Q_{\max}}\right)_{\text{total, 2D}} = \left(\frac{Q}{Q_{\max}}\right)_1 + \left(\frac{Q}{Q_{\max}}\right)_2 \left[1 - \left(\frac{Q}{Q_{\max}}\right)_1\right] \quad (4-53)$$

Transient heat transfer for a three-dimensional body formed by the intersection of three one-dimensional bodies 1, 2, and 3 is given by

$$\begin{aligned} \left(\frac{Q}{Q_{\max}}\right)_{\text{total, 3D}} &= \left(\frac{Q}{Q_{\max}}\right)_1 + \left(\frac{Q}{Q_{\max}}\right)_2 \left[1 - \left(\frac{Q}{Q_{\max}}\right)_1\right] \\ &\quad + \left(\frac{Q}{Q_{\max}}\right)_3 \left[1 - \left(\frac{Q}{Q_{\max}}\right)_1\right] \left[1 - \left(\frac{Q}{Q_{\max}}\right)_2\right] \end{aligned} \quad (4-54)$$

The use of the product solution in transient two- and three-dimensional heat conduction problems is illustrated in the following examples.

### EXAMPLE 4-8 Cooling of a Short Brass Cylinder

A short brass cylinder of diameter  $D = 10$  cm and height  $H = 12$  cm is initially at a uniform temperature  $T_i = 120^\circ\text{C}$ . The cylinder is now placed in atmospheric air at  $25^\circ\text{C}$ , where heat transfer takes place by convection, with a heat transfer coefficient of  $h = 60 \text{ W/m}^2\cdot\text{K}$ . Calculate the temperature at (a) the center of the cylinder and (b) the center of the top surface of the cylinder 15 min after the start of the cooling.

**SOLUTION** A short cylinder is allowed to cool in atmospheric air. The temperatures at the centers of the cylinder and the top surface are to be determined.

**Assumptions** 1 Heat conduction in the short cylinder is two-dimensional, and thus the temperature varies in both the axial  $x$ - and the radial  $r$ -directions.

2 The thermal properties of the cylinder and the heat transfer coefficient are constant. 3 The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The properties of brass at room temperature are  $k = 110 \text{ W/m}\cdot\text{K}$  and  $\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$  (Table A-3). More accurate results can be obtained by using properties at average temperature.

**Analysis** (a) This short cylinder can physically be formed by the intersection of a long cylinder of radius  $r_o = 5$  cm and a plane wall of thickness  $2L = 12$  cm, as

FIGURE 4-38

A long solid bar of rectangular profile  $a \times b$  is the *intersection* of two plane walls of thicknesses  $a$  and  $b$ .

$T_\infty = 25^\circ\text{C}$   
 $h = 60 \text{ W/m}^2\cdot\text{K}$

FIGURE 4-39

Schematic for Example 4-8.

shown in Fig. 4-39. The dimensionless temperature at the center of the plane wall is determined from Fig. 4-17a to be

$$\left. \begin{aligned} \tau &= \frac{\alpha t}{L^2} = \frac{(3.39 \times 10^{-5} \text{ m}^2/\text{s})(900 \text{ s})}{(0.06 \text{ m})^2} = 8.48 \\ \frac{1}{\text{Bi}} &= \frac{k}{hL} = \frac{110 \text{ W/m}\cdot\text{K}}{(60 \text{ W/m}^2\cdot\text{K})(0.06 \text{ m})} = 30.6 \end{aligned} \right\} \theta_{\text{wall}}(0, t) = \frac{T(0, t) - T_\infty}{T_i - T_\infty} = 0.8$$

Similarly, at the center of the cylinder, we have

$$\left. \begin{aligned} \tau &= \frac{\alpha t}{r_o^2} = \frac{(3.39 \times 10^{-5} \text{ m}^2/\text{s})(900 \text{ s})}{(0.05 \text{ m})^2} = 12.2 \\ \frac{1}{\text{Bi}} &= \frac{k}{hr_o} = \frac{110 \text{ W/m}\cdot\text{K}}{(60 \text{ W/m}^2\cdot\text{K})(0.05 \text{ m})} = 36.7 \end{aligned} \right\} \theta_{\text{cyl}}(0, t) = \frac{T(0, t) - T_\infty}{T_i - T_\infty} = 0.5$$

Therefore,

$$\left( \frac{T(0, 0, t) - T_\infty}{T_i - T_\infty} \right)_{\text{cylinder}}^{\text{short}} = \theta_{\text{wall}}(0, t) \times \theta_{\text{cyl}}(0, t) = 0.8 \times 0.5 = 0.4$$

and

$$T(0, 0, t) = T_\infty + 0.4(T_i - T_\infty) = 25 + 0.4(120 - 25) = 63^\circ\text{C}$$

This is the temperature at the center of the short cylinder, which is also the center of both the long cylinder and the plate.

(b) The center of the top surface of the cylinder is still at the center of the long cylinder ( $r = 0$ ), but at the outer surface of the plane wall ( $x = L$ ). Therefore, we first need to find the surface temperature of the wall. Noting that  $x = L = 0.06 \text{ m}$ ,

$$\left. \begin{aligned} \frac{x}{L} &= \frac{0.06 \text{ m}}{0.06 \text{ m}} = 1 \\ \frac{1}{\text{Bi}} &= \frac{k}{hL} = \frac{110 \text{ W/m}\cdot\text{K}}{(60 \text{ W/m}^2\cdot\text{K})(0.06 \text{ m})} = 30.6 \end{aligned} \right\} \frac{T(L, t) - T_\infty}{T_0 - T_\infty} = 0.98$$

Then

$$\theta_{\text{wall}}(L, t) = \frac{T(L, t) - T_\infty}{T_i - T_\infty} = \left( \frac{T(L, t) - T_\infty}{T_0 - T_\infty} \right) \left( \frac{T_0 - T_\infty}{T_i - T_\infty} \right) = 0.98 \times 0.8 = 0.784$$

Therefore,

$$\left( \frac{T(L, 0, t) - T_\infty}{T_i - T_\infty} \right)_{\text{cylinder}}^{\text{short}} = \theta_{\text{wall}}(L, t) \theta_{\text{cyl}}(0, t) = 0.784 \times 0.5 = 0.392$$

and

$$T(L, 0, t) = T_\infty + 0.392(T_i - T_\infty) = 25 + 0.392(120 - 25) = 62.2^\circ\text{C}$$

which is the temperature at the center of the top surface of the cylinder.

**EXAMPLE 4-9 Heat Transfer from a Short Cylinder**

Determine the total heat transfer from the short brass cylinder ( $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 0.380 \text{ kJ/kg}\cdot\text{K}$ ) discussed in Example 4-8.

**SOLUTION** We first determine the maximum heat that can be transferred from the cylinder, which is the sensible energy content of the cylinder relative to its environment:

$$m = \rho V = \rho \pi r_o^2 H = (8530 \text{ kg/m}^3) \pi (0.05 \text{ m})^2 (0.12 \text{ m}) = 8.04 \text{ kg}$$

$$Q_{\max} = mc_p(T_i - T_\infty) = (8.04 \text{ kg})(0.380 \text{ kJ/kg}\cdot\text{K})(120 - 25)^\circ\text{C} = 290.2 \text{ kJ}$$

Then we determine the dimensionless heat transfer ratios for both geometries. For the plane wall, it is determined from Fig. 4-17c to be

$$\left. \begin{aligned} \text{Bi} &= \frac{1}{1/\text{Bi}} = \frac{1}{30.6} = 0.0327 \\ \frac{h^2 \alpha t}{k^2} &= \text{Bi}^2 \tau = (0.0327)^2 (8.48) = 0.0091 \end{aligned} \right\} \left( \frac{Q}{Q_{\max}} \right)_{\text{plane}} = 0.23$$

Similarly, for the cylinder, we have

$$\left. \begin{aligned} \text{Bi} &= \frac{1}{1/\text{Bi}} = \frac{1}{36.7} = 0.0272 \\ \frac{h^2 \alpha t}{k^2} &= \text{Bi}^2 \tau = (0.0272)^2 (12.2) = 0.0090 \end{aligned} \right\} \left( \frac{Q}{Q_{\max}} \right)_{\text{cylinder}} = 0.47$$

Then the heat transfer ratio for the short cylinder is, from Eq. 4-53,

$$\begin{aligned} \left( \frac{Q}{Q_{\max}} \right)_{\text{short cyl}} &= \left( \frac{Q}{Q_{\max}} \right)_1 + \left( \frac{Q}{Q_{\max}} \right)_2 \left[ 1 - \left( \frac{Q}{Q_{\max}} \right)_1 \right] \\ &= 0.23 + 0.47(1 - 0.23) = 0.592 \end{aligned}$$

Therefore, the total heat transfer from the cylinder during the first 15 min of cooling is

$$Q = 0.592 Q_{\max} = 0.592 \times (290.2 \text{ kJ}) = 172 \text{ kJ}$$

**EXAMPLE 4-10 Cooling of a Long Cylinder by Water**

A semi-infinite aluminum cylinder of diameter  $D = 20 \text{ cm}$  is initially at a uniform temperature  $T_i = 200^\circ\text{C}$ . The cylinder is now placed in water at  $15^\circ\text{C}$  where heat transfer takes place by convection, with a heat transfer coefficient of  $h = 120 \text{ W/m}^2\cdot\text{K}$ . Determine the temperature at the center of the cylinder 15 cm from the end surface 5 min after the start of the cooling.

**SOLUTION** A semi-infinite aluminum cylinder is cooled by water. The temperature at the center of the cylinder 15 cm from the end surface is to be determined.

**Assumptions** 1 Heat conduction in the semi-infinite cylinder is two-dimensional, and thus the temperature varies in both the axial  $x$ - and the

**FIGURE 4-40**

Schematic for Example 4-10.

radial  $r$ -directions. **2** The thermal properties of the cylinder and the heat transfer coefficient are constant. **3** The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The properties of aluminum at room temperature are  $k = 237 \text{ W/m}\cdot\text{K}$  and  $\alpha = 9.71 \times 10^{-5} \text{ m}^2/\text{s}$  (Table A-3). More accurate results can be obtained by using properties at average temperature.

**Analysis** This semi-infinite cylinder can physically be formed by the intersection of an infinite cylinder of radius  $r_o = 10\text{ cm}$  and a semi-infinite medium, as shown in Fig. 4-40.

We solve this problem using the one-term solution relation for the cylinder and the analytic solution for the semi-infinite medium. First we consider the infinitely long cylinder and evaluate the Biot number:

$$\text{Bi} = \frac{hr_o}{k} = \frac{(120 \text{ W/m}^2\cdot\text{K})(0.1 \text{ m})}{237 \text{ W/m}\cdot\text{K}} = 0.05$$

The coefficients  $\lambda_1$  and  $A_1$  for a cylinder corresponding to this Bi are determined from Table 4-2 to be  $\lambda_1 = 0.3126$  and  $A_1 = 1.0124$ . The Fourier number in this case is

$$\tau = \frac{\alpha t}{r_o^2} = \frac{(9.71 \times 10^{-5} \text{ m}^2/\text{s})(5 \times 60 \text{ s})}{(0.1 \text{ m})^2} = 2.91 > 0.2$$

and thus the one-term approximation is applicable. Substituting these values into Eq. 4-27 gives

$$\theta_0 = \theta_{\text{cyl}}(0, t) = A_1 e^{-\lambda_1^2 \tau} = 1.0124 e^{-(0.3126)^2(2.91)} = 0.762$$

The solution for the semi-infinite solid can be determined from

$$1 - \theta_{\text{semi-inf}}(x, t) = \operatorname{erfc} \left( \frac{x}{2\sqrt{\alpha t}} \right) - \exp \left( \frac{hx}{k} + \frac{h^2 \alpha t}{k^2} \right) \left[ \operatorname{erfc} \left( \frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k} \right) \right]$$

First we determine the various quantities in parentheses:

$$\eta = \frac{x}{2\sqrt{\alpha t}} = \frac{0.15 \text{ m}}{2\sqrt{(9.71 \times 10^{-5} \text{ m}^2/\text{s})(5 \times 60 \text{ s})}} = 0.44$$

$$\frac{h\sqrt{\alpha t}}{k} = \frac{(120 \text{ W/m}^2\cdot\text{K})\sqrt{(9.71 \times 10^{-5} \text{ m}^2/\text{s})(300 \text{ s})}}{237 \text{ W/m}\cdot\text{K}} = 0.086$$

$$\frac{hx}{k} = \frac{(120 \text{ W/m}^2\cdot\text{K})(0.15 \text{ m})}{237 \text{ W/m}\cdot\text{K}} = 0.0759$$

$$\frac{h^2 \alpha t}{k^2} = \left( \frac{h\sqrt{\alpha t}}{k} \right)^2 = (0.086)^2 = 0.0074$$

Substituting and evaluating the complementary error functions from Table 4-4,

$$\begin{aligned} \theta_{\text{semi-inf}}(x, t) &= 1 - \operatorname{erfc}(0.44) + \exp(-0.0759 + 0.0074) \operatorname{erfc}(0.44 + 0.086) \\ &= 1 - 0.5338 + \exp(0.0833) \times 0.457 \\ &= 0.963 \end{aligned}$$

Now we apply the product solution to get

$$\left( \frac{T(x, 0, t) - T_{\infty}}{T_i - T_{\infty}} \right)_{\text{cylinder}} = \theta_{\text{semi-inf}}(x, t) \theta_{\text{cyl}}(0, t) = 0.963 \times 0.762 = 0.734$$

and

$$T(x, 0, t) = T_{\infty} + 0.734(T_i - T_{\infty}) = 15 + 0.734(200 - 15) = 151^{\circ}\text{C}$$

which is the temperature at the center of the cylinder 15 cm from the exposed bottom surface.

### EXAMPLE 4–11 Refrigerating Steaks while Avoiding Frostbite

In a meat processing plant, 1-in-thick steaks initially at  $75^{\circ}\text{F}$  are to be cooled in the racks of a large refrigerator that is maintained at  $5^{\circ}\text{F}$  (Fig. 4–41). The steaks are placed close to each other, so that heat transfer from the 1-in-thick edges is negligible. The entire steak is to be cooled below  $45^{\circ}\text{F}$ , but its temperature is not to drop below  $35^{\circ}\text{F}$  at any point during refrigeration to avoid “frostbite.” The convection heat transfer coefficient and thus the rate of heat transfer from the steak can be controlled by varying the speed of a circulating fan inside. Determine the heat transfer coefficient  $h$  that will enable us to meet both temperature constraints while keeping the refrigeration time to a minimum. The steak can be treated as a homogeneous layer having the properties  $\rho = 74.9 \text{ lbm/ft}^3$ ,  $c_p = 0.98 \text{ Btu/lbm}\cdot^{\circ}\text{F}$ ,  $k = 0.26 \text{ Btu/h}\cdot\text{ft}\cdot^{\circ}\text{F}$ , and  $\alpha = 0.0035 \text{ ft}^2/\text{h}$ .

**SOLUTION** Steaks are to be cooled in a refrigerator maintained at  $5^{\circ}\text{F}$ . The heat transfer coefficient that allows cooling the steaks below  $45^{\circ}\text{F}$  while avoiding frostbite is to be determined.

**Assumptions** 1 Heat conduction through the steaks is one-dimensional since the steaks form a large layer relative to their thickness and there is thermal symmetry about the center plane. 2 The thermal properties of the steaks and the heat transfer coefficient are constant. 3 The Fourier number is  $\tau > 0.2$  so that the one-term approximate solutions are applicable.

**Properties** The properties of the steaks are as given in the problem statement.

**Analysis** The lowest temperature in the steak occurs at the surfaces and the highest temperature at the center at a given time, since the inner part is the last place to be cooled. In the limiting case, the surface temperature at  $x = L = 0.5 \text{ in}$  from the center will be  $35^{\circ}\text{F}$ , while the midplane temperature is  $45^{\circ}\text{F}$  in an environment at  $5^{\circ}\text{F}$ . Then, from Fig. 4–17b, we obtain

$$\left. \begin{aligned} \frac{x}{L} &= \frac{0.5 \text{ in}}{0.5 \text{ in}} = 1 \\ \frac{T(L, t) - T_{\infty}}{T_0 - T_{\infty}} &= \frac{35 - 5}{45 - 5} = 0.75 \end{aligned} \right\} \frac{1}{\text{Bi}} = \frac{k}{hL} = 1.5$$

which gives

$$h = \frac{1}{1.5} \frac{k}{L} = \frac{0.26 \text{ Btu/h}\cdot\text{ft}\cdot^{\circ}\text{F}}{1.5(0.5/12 \text{ ft})} = 4.16 \text{ Btu/h}\cdot\text{ft}^2\cdot^{\circ}\text{F}$$

**FIGURE 4–41**  
Schematic for Example 4–11.

**Discussion** The convection heat transfer coefficient should be kept below this value to satisfy the constraints on the temperature of the steak during refrigeration. We can also meet the constraints by using a lower heat transfer coefficient, but doing so would extend the refrigeration time unnecessarily.

The restrictions that are inherent in the use of Heisler charts and the one-term solutions (or any other analytical solutions) can be lifted by using the numerical methods discussed in Chapter 5.

## TOPIC OF SPECIAL INTEREST\*

FIGURE 4-42

Typical growth curve of microorganisms.

FIGURE 4-43

The factors that affect the rate of growth of microorganisms.

### Refrigeration and Freezing of Foods

#### Control of Microorganisms in Foods

Microorganisms such as *bacteria*, *yeasts*, *molds*, and *viruses* are widely encountered in air, water, soil, living organisms, and unprocessed food items, and cause *off-flavors* and *odors*, *slime production*, *changes* in the texture and appearances, and the eventual *spoilage* of foods. Holding perishable foods at warm temperatures is the primary cause of spoilage, and the prevention of food spoilage and the premature degradation of quality due to microorganisms is the largest application area of refrigeration. The first step in controlling microorganisms is to understand what they are and the factors that affect their transmission, growth, and destruction.

Of the various kinds of microorganisms, *bacteria* are the prime cause for the spoilage of foods, especially moist foods. Dry and acidic foods create an undesirable environment for the growth of bacteria, but not for the growth of yeasts and molds. *Molds* are also encountered on moist surfaces, cheese, and spoiled foods. Specific *viruses* are encountered in certain animals and humans, and poor sanitation practices such as keeping processed foods in the same area as the uncooked ones and being careless about handwashing can cause the contamination of food products.

When *contamination* occurs, the microorganisms start to adapt to the new environmental conditions. This initial slow or no-growth period is called the **lag phase**, and the shelf life of a food item is directly proportional to the length of this phase (Fig. 4-42). The adaptation period is followed by an *exponential growth* period during which the population of microorganisms can double two or more times every hour under favorable conditions unless drastic sanitation measures are taken. The depletion of nutrients and the accumulation of toxins slow down the growth and start the *death* period.

The *rate of growth* of microorganisms in a food item depends on the characteristics of the food itself such as the chemical structure, pH level, presence of inhibitors and competing microorganisms, and water activity as well as the environmental conditions such as the temperature and relative humidity of the environment and the air motion (Fig. 4-43).

\*This section can be skipped without a loss of continuity.

Microorganisms need *food* to grow and multiply, and their nutritional needs are readily provided by the carbohydrates, proteins, minerals, and vitamins in a food. Different types of microorganisms have different nutritional needs, and the types of nutrients in a food determine the types of microorganisms that may dwell on them. The preservatives added to the food may also inhibit the growth of certain microorganisms. Different kinds of microorganisms that exist compete for the same food supply, and thus the composition of microorganisms in a food at any time depends on the *initial make-up* of the microorganisms.

All living organisms need *water* to grow, and microorganisms cannot grow in foods that are not sufficiently moist. Microbiological growth in refrigerated foods such as fresh fruits, vegetables, and meats starts at the *exposed surfaces* where contamination is most likely to occur. Fresh meat in a package left in a room will spoil quickly, as you may have noticed. A meat carcass hung in a controlled environment, on the other hand, will age healthily as a result of *dehydration* on the outer surface, which inhibits microbiological growth there and protects the carcass.

Microorganism growth in a food item is governed by the combined effects of the *characteristics of the food* and the *environmental factors*. We cannot do much about the characteristics of the food, but we certainly can alter the environmental conditions to more desirable levels through *heating, cooling, ventilating, humidification, dehumidification*, and control of the *oxygen* levels. The growth rate of microorganisms in foods is a strong function of temperature, and temperature control is the single most effective mechanism for controlling the growth rate.

Microorganisms grow best at “warm” temperatures, usually between 20 and 60°C. The growth rate *declines* at high temperatures, and *death* occurs at still higher temperatures, usually above 70°C for most microorganisms. *Cooling* is an effective and practical way of reducing the growth rate of microorganisms and thus extending the *shelf life* of perishable foods. A temperature of 4°C or lower is considered to be a safe refrigeration temperature. Sometimes a small increase in refrigeration temperature may cause a large increase in the growth rate, and thus a considerable decrease in shelf life of the food (Fig. 4–44). The growth rate of some microorganisms, for example, doubles for each 3°C rise in temperature.

Another factor that affects microbiological growth and transmission is the *relative humidity* of the environment, which is a measure of the water content of the air. High humidity in *cold rooms* should be avoided since condensation that forms on the walls and ceiling creates the proper environment for *mold growth* and buildups. The drip of contaminated condensate onto food products in the room poses a potential health hazard.

Different microorganisms react differently to the presence of oxygen in the environment. Some microorganisms such as molds require oxygen for growth, while some others cannot grow in the presence of oxygen. Some grow best in low-oxygen environments, while others grow in environments regardless of the amount of oxygen. Therefore, the growth of certain microorganisms can be controlled by controlling the *amount of oxygen* in the environment. For example, vacuum packaging inhibits the growth of

**FIGURE 4-44**  
The rate of growth of microorganisms in a food product increases exponentially with increasing environmental temperature.

**FIGURE 4-45**

Freezing may stop the growth of microorganisms, but it may not necessarily kill them.

**FIGURE 4-46**

Recommended refrigeration and freezing temperatures for most perishable foods.

microorganisms that require oxygen. Also, the storage life of some fruits can be extended by reducing the oxygen level in the storage room.

Microorganisms in food products can be controlled by (1) *preventing contamination* by following strict sanitation practices, (2) *inhibiting* growth by altering the environmental conditions, and (3) *destroying* the organisms by heat treatment or chemicals. The best way to minimize contamination in food processing areas is to use fine air filters in ventilation systems to capture the *dust particles* that transport the bacteria in the air. Of course, the filters must remain dry since microorganisms can grow in wet filters. Also, the ventilation system must maintain a positive pressure in the food processing areas to prevent any airborne contaminants from entering inside by infiltration. The elimination of *condensation* on the walls and the ceiling of the facility and the diversion of *plumbing* condensation drip pans of refrigerators to the drain system are two other preventive measures against contamination. Drip systems must be cleaned regularly to prevent microbiological growth in them. Also, any *contact* between raw and cooked food products should be minimized, and cooked products must be stored in rooms with positive pressures. Frozen foods must be kept at  $-18^{\circ}\text{C}$  or below, and utmost care should be exercised when food products are packaged after they are frozen to avoid contamination during packaging.

The growth of microorganisms is best controlled by keeping the *temperature* and *relative humidity* of the environment in the desirable range. Keeping the relative humidity below 60 percent, for example, prevents the growth of all microorganisms on the surfaces. Microorganisms can be destroyed by *heating* the food product to high temperatures (usually above  $70^{\circ}\text{C}$ ), by treating them with *chemicals*, or by exposing them to *ultraviolet light* or *solar radiation*.

Distinction should be made between *survival* and *growth* of microorganisms. A particular microorganism that may not grow at some low temperature may be able to survive at that temperature for a very long time (Fig. 4-45). Therefore, freezing is not an effective way of killing microorganisms. In fact, some microorganism cultures are preserved by freezing them at very low temperatures. The *rate of freezing* is also an important consideration in the refrigeration of foods since some microorganisms adapt to low temperatures and grow at those temperatures when the cooling rate is very low.

## Refrigeration and Freezing of Foods

The *storage life* of fresh perishable foods such as meats, fish, vegetables, and fruits can be extended by several days by storing them at temperatures just above freezing, usually between 1 and  $4^{\circ}\text{C}$ . The storage life of foods can be extended by several months by freezing and storing them at subfreezing temperatures, usually between  $-18$  and  $-35^{\circ}\text{C}$ , depending on the particular food (Fig. 4-46).

Refrigeration *slows down* the chemical and biological processes in foods, and the accompanying deterioration and loss of quality and nutrients. Sweet corn, for example, may lose half of its initial sugar content in one day at  $21^{\circ}\text{C}$ , but only 5 percent of it at  $0^{\circ}\text{C}$ . Fresh asparagus may lose 50 percent of its vitamin C content in one day at  $20^{\circ}\text{C}$ , but in 12 days

at 0°C. Refrigeration also extends the shelf life of products. The first appearance of unsightly yellowing of broccoli, for example, may be delayed by three or more days by refrigeration.

Early attempts to freeze food items resulted in poor-quality products because of the large ice crystals that formed. It was determined that the *rate of freezing* has a major effect on the size of ice crystals and the quality, texture, and nutritional and sensory properties of many foods. During *slow freezing*, ice crystals can grow to a large size, whereas during *fast freezing* a large number of ice crystals start forming at once and are much smaller in size. Large ice crystals are not desirable since they can *puncture* the walls of the cells, causing a degradation of texture and a loss of natural juices during thawing. A *crust* forms rapidly on the outer layer of the product and seals in the juices, aromatics, and flavoring agents. The product quality is also affected adversely by temperature fluctuations of the storage room.

The ordinary refrigeration of foods involves *cooling* only without any phase change. The *freezing* of foods, on the other hand, involves three stages: *cooling* to the freezing point (removing the sensible heat), *freezing* (removing the latent heat), and *further cooling* to the desired subfreezing temperature (removing the sensible heat of frozen food), as shown in Figure 4-47.

## Beef Products

Meat carcasses in slaughterhouses should be cooled *as fast as possible* to a uniform temperature of about 1.7°C to reduce the growth rate of microorganisms that may be present on carcass surfaces, and thus minimize spoilage. The right level of *temperature*, *humidity*, and *air motion* should be selected to prevent excessive shrinkage, toughening, and discoloration.

The deep body temperature of an animal is about 39°C, but this temperature tends to rise a couple of degrees in the midsections after slaughter as a result of the *heat generated* during the biological reactions that occur in the cells. The temperature of the exposed surfaces, on the other hand, tends to drop as a result of heat losses. The thickest part of the carcass is the *round*, and the center of the round is the last place to cool during chilling. Therefore, the cooling of the carcass can best be monitored by inserting a thermometer deep into the central part of the round.

About 70 percent of the beef carcass is water, and the carcass is cooled mostly by *evaporative cooling* as a result of moisture migration toward the surface where evaporation occurs. But this shrinking translates into a loss of salable mass that can amount to 2 percent of the total mass during an overnight chilling. To prevent *excessive* loss of mass, carcasses are usually washed or sprayed with water prior to cooling. With adequate care, spray chilling can eliminate carcass cooling shrinkage almost entirely.

The average total mass of dressed beef, which is normally split into two sides, is about 300 kg, and the average specific heat of the carcass is about 3.14 kJ/kg·K (Table 4-6). The *chilling room* must have a capacity equal to the daily kill of the slaughterhouse, which may be several hundred. A beef carcass is washed before it enters the chilling room and absorbs a large amount of water (about 3.6 kg) at its surface during the washing process. This does not represent a net mass gain, however, since it is lost

**FIGURE 4-47**  
Typical freezing curve of a food item.

**TABLE 4-6**

Thermal properties of beef

| Quantity              | Typical value          |
|-----------------------|------------------------|
| Average density       | 1070 kg/m <sup>3</sup> |
| Specific heat:        |                        |
| Above freezing        | 3.14 kJ/kg·K           |
| Below freezing        | 1.70 kJ/kg·K           |
| Freezing point        | -2.7°C                 |
| Latent heat of fusion | 249 kJ/kg              |
| Thermal conductivity  | 0.41 W/m·K<br>(at 6°C) |

**FIGURE 4-48**

Typical cooling curve of a beef carcass in the chilling and holding rooms at an average temperature of 0°C.

From ASHRAE, *Handbook: Refrigeration*, Chap. 11, Fig. 2.

by dripping or evaporation in the chilling room during cooling. Ideally, the carcass does not lose or gain any net weight as it is cooled in the chilling room. However, it does lose about 0.5 percent of the total mass in the *holding room* as it continues to cool. The actual product loss is determined by first weighing the dry carcass before washing and then weighing it again after it is cooled.

The refrigerated air temperature in the chilling room of beef carcasses must be sufficiently high to avoid *freezing* and *discoloration* on the outer surfaces of the carcass. This means a long residence time for the massive beef carcasses in the chilling room to cool to the desired temperature. Beef carcasses are only partially cooled at the end of an overnight stay in the chilling room. The temperature of a beef carcass drops to 1.7 to 7°C at the surface and to about 15°C in mid parts of the round in 10 h. It takes another day or two in the *holding room* maintained at 1 to 2°C to complete *chilling* and *temperature equalization*. But hog carcasses are fully chilled during that period because of their smaller size. The *air circulation* in the holding room is kept at minimum levels to avoid excessive moisture loss and discoloration. The refrigeration load of the holding room is much smaller than that of the chilling room, and thus it requires a smaller refrigeration system.

Beef carcasses intended for distant markets are shipped the day after slaughter in refrigerated trucks, where the rest of the cooling is done. This practice makes it possible to deliver fresh meat long distances in a timely manner.

The variation in temperature of the beef carcass during cooling is given in Figure 4-48. Initially, the cooling process is dominated by *sensible heat transfer*. Note that the average temperature of the carcass is reduced by about 28°C (from 36 to 8°C) in 20 h. The cooling rate of the carcass could be increased by *lowering* the refrigerated air temperature and *increasing* the air velocity, but such measures also increase the risk of *surface freezing*.

Most meats are judged on their **tenderness**, and the preservation of tenderness is an important consideration in the refrigeration and freezing of meats. Meat consists primarily of bundles of tiny *muscle fibers* bundled together inside long strings of *connective tissues* that hold it together.

The tenderness of a certain cut of beef depends on the location of the cut, the age, and the activity level of the animal. Cuts from the relatively inactive mid-backbone section of the animal such as short loins, sirloin, and prime ribs are more tender than the cuts from the active parts such as the legs and the neck (Fig. 4–49). The more active the animal, the more the connective tissue, and the tougher the meat. The meat of an older animal is more flavorful, however, and is preferred for stewing since the toughness of the meat does not pose a problem for moist-heat cooking such as boiling. The protein *collagen*, which is the main component of the connective tissue, softens and dissolves in hot and moist environments and gradually transforms into *gelatin*, and tenderizes the meat.

The old saying “one should either cook an animal immediately after slaughter or wait at least two days” has a lot of truth in it. The biomechanical reactions in the muscle continue after the slaughter until the energy supplied to the muscle to do work diminishes. The muscle then stiffens and goes into *rigor mortis*. This process begins several hours after the animal is slaughtered and continues for 12 to 36 h until an enzymatic action sets in and tenderizes the connective tissue, as shown in Figure 4–50. It takes about seven days to complete tenderization naturally in storage facilities maintained at 2°C. Electrical stimulation also causes the meat to be tender. To avoid toughness, fresh meat should not be frozen before rigor mortis has passed.

You have probably noticed that steaks are tender and rather tasty when they are hot but toughen as they cool. This is because the gelatin that formed during cooking thickens as it cools, and meat loses its tenderness. So it is no surprise that first-class restaurants serve their steak on hot thick plates that keep the steaks warm for a long time. Also, cooking *softens* the connective tissue but *toughens* the tender muscle fibers. Therefore, barbecuing on *low heat* for a long time results in a tough steak.

Variety meats intended for long-term storage must be frozen rapidly to reduce spoilage and preserve quality. Perhaps the first thought that comes to mind to freeze meat is to place the meat packages into the *freezer* and wait. But the freezing time is *too long* in this case, especially for large boxes. For example, the core temperature of a 4-cm-deep box containing 32 kg of variety meat can be as high as 16°C 24 h after it is placed into a –30°C freezer. The freezing time of large boxes can be shortened considerably by adding some *dry ice* into it.

A more effective method of freezing, called *quick chilling*, involves the use of lower air temperatures, –40 to –30°C, with higher velocities of 2.5 m/s to 5 m/s over the product (Fig. 4–51). The internal temperature should be lowered to –4°C for products to be transferred to a storage freezer and to –18°C for products to be shipped immediately. The *rate of freezing* depends on the *package material* and its insulating properties, the *thickness* of the largest box, the *type* of meat, and the *capacity* of the refrigeration system. Note that the air temperature will rise excessively during initial stages of freezing and increase the freezing time if the capacity of the system is inadequate. A smaller refrigeration system will be adequate if dry ice is to be used in packages. Shrinkage during freezing varies from about 0.5 to 1 percent.

Variation of tenderness of meat stored at 2°C with time after slaughter.

FIGURE 4–51

The freezing time of meat can be reduced considerably by using low temperature air at high velocity.

**TABLE 4-7**

Storage life of frozen meat products at different storage temperatures (from ASHRAE Handbook: *Refrigeration*, Chap. 10, Table 7)

| Product      | Storage Life, Months |       |       |
|--------------|----------------------|-------|-------|
|              | Temperature          |       |       |
|              | -12°C                | -18°C | -23°C |
| Beef         | 4–12                 | 6–18  | 12–24 |
| Lamb         | 3–8                  | 6–16  | 12–18 |
| Veal         | 3–4                  | 4–14  | 8     |
| Pork         | 2–6                  | 4–12  | 8–15  |
| Chopped beef | 3–4                  | 4–6   | 8     |
| Cooked foods | 2–3                  | 2–4   |       |

Although the average freezing point of lean meat can be taken to be  $-2^{\circ}\text{C}$  with a latent heat of 249 kJ/kg, it should be remembered that freezing occurs over a *temperature range*, with most freezing occurring between  $-1$  and  $-4^{\circ}\text{C}$ . Therefore, cooling the meat through this temperature range and removing the latent heat takes the most time during freezing.

Meat can be kept at an internal temperature of  $-2$  to  $-1^{\circ}\text{C}$  for local use and storage for *under a week*. Meat must be frozen and stored at much lower temperatures for *long-term storage*. The lower the storage temperature, the longer the storage life of meat products, as shown in Table 4-7.

The *internal temperature* of carcasses entering the cooling sections varies from  $38$  to  $41^{\circ}\text{C}$  for hogs and from  $37$  to  $39^{\circ}\text{C}$  for lambs and calves. It takes about 15 h to cool the hogs and calves to the recommended temperature of  $3$  to  $4^{\circ}\text{C}$ . The cooling-room temperature is maintained at  $-1$  to  $0^{\circ}\text{C}$  and the temperature difference between the refrigerant and the cooling air is kept at about  $6^{\circ}\text{C}$ . Air is circulated at a rate of about 7 to 12 air changes per hour. *Lamb carcasses* are cooled to an internal temperature of  $1$  to  $2^{\circ}\text{C}$ , which takes about 12 to 14 h, and are held at that temperature with 85 to 90 percent relative humidity until shipped or processed. The recommended rate of *air circulation* is 50 to 60 air changes per hour during the first 4 to 6 h, which is reduced to 10 to 12 changes per hour afterward.

*Freezing* does not seem to affect the *flavor* of meat much, but it affects the *quality* in several ways. The *rate* and *temperature* of freezing may influence color, tenderness, and drip. Rapid freezing increases tenderness and reduces the tissue damage and the amount of drip after thawing. Storage at low freezing temperatures causes significant changes in *animal fat*. Frozen pork experiences more undesirable changes during storage because of its fat structure, and thus its acceptable storage period is shorter than that of beef, veal, or lamb.

Meat storage facilities usually have a *refrigerated shipping dock* where the orders are assembled and shipped out. Such docks save valuable storage space from being used for shipping purposes and provide a more acceptable working environment for the employees. Packing plants that ship whole or half carcasses in bulk quantities may not need a shipping dock; a load-out door is often adequate for such cases.

A refrigerated *shipping dock*, as shown in Figure 4-52, reduces the *refrigeration load* of freezers or coolers and prevents *temperature fluctuations* in the storage area. It is often adequate to maintain the shipping docks at  $4$  to  $7^{\circ}\text{C}$  for the coolers and about  $1.5^{\circ}\text{C}$  for the freezers. The dew point of the dock air should be below the product temperature to avoid condensation on the surface of the products and loss of quality. The rate of *airflow* through the loading doors and other openings is proportional to the *square root* of the temperature difference, and thus reducing the temperature difference at the opening by half by keeping the shipping dock at the average temperature reduces the rate of airflow into the dock and thus into the freezer by  $1 - \sqrt{0.5} \cong 0.3$ , or 30 percent. Also, the air that flows into the freezer is already cooled to about  $1.5^{\circ}\text{C}$  by the refrigeration unit of the dock, which represents about 50 percent of the cooling load of the incoming air. Thus, the net effect of the refrigerated shipping dock is a reduction of the *infiltration load* of the freezer by about 65 percent since

**FIGURE 4-52**

A refrigerated truck dock for loading frozen items to a refrigerated truck.

$1 - 0.7 \times 0.5 = 0.65$ . The net gain is equal to the difference between the reduction of the infiltration load of the freezer and the refrigeration load of the shipping dock. Note that the dock refrigerators operate at much higher temperatures ( $1.5^{\circ}\text{C}$  instead of about  $-23^{\circ}\text{C}$ ), and thus they consume much less power for the same amount of cooling.

## Poultry Products

Poultry products can be preserved by *ice-chilling* to 1 to  $2^{\circ}\text{C}$  or *deep chilling* to about  $-2^{\circ}\text{C}$  for short-term storage, or by *freezing* them to  $-18^{\circ}\text{C}$  or below for long-term storage. Poultry processing plants are completely *automated*, and the small size of the birds makes continuous conveyor line operation feasible.

The birds are first electrically stunned before cutting to prevent struggling. Following a 90- to 120-s bleeding time, the birds are *scalded* by immersing them into a tank of warm water, usually at  $51$  to  $55^{\circ}\text{C}$ , for up to 120 s to loosen the feathers. Then the feathers are removed by feather-picking machines, and the eviscerated carcass is *washed* thoroughly before chilling. The internal temperature of the birds ranges from  $24$  to  $35^{\circ}\text{C}$  after washing, depending on the temperatures of the ambient air and the washing water as well as the extent of washing.

To control the microbial growth, the USDA regulations require that poultry be chilled to  $4^{\circ}\text{C}$  or below in less than 4 h for carcasses of less than 1.8 kg, in less than 6 h for carcasses of 1.8 to 3.6 kg, and in less than 8 h for carcasses more than 3.6 kg. Meeting these requirements today is not difficult since the slow *air chilling* is largely replaced by the rapid *immersion chilling* in tanks of slush ice. Immersion chilling has the added benefit that it not only prevents dehydration, but it causes a *net absorption of water* and thus increases the mass of salable product. Cool air chilling of unpacked poultry can cause a moisture loss of 1 to 2 percent, while water immersion chilling can cause a moisture absorption of 4 to 15 percent (Fig. 4–53). Water spray chilling can cause a moisture absorption of up to 4 percent. Most water absorbed is held between the flesh and the skin and the connective tissues in the skin. In immersion chilling, some soluble solids are lost from the carcass to the water, but the loss has no significant effect on flavor.

Many slush ice tank chillers today are replaced by *continuous flow*-type immersion slush ice chillers. Continuous slush ice-chillers can reduce the internal temperature of poultry from  $32$  to  $4^{\circ}\text{C}$  in about 30 minutes at a rate up to 10,000 birds per hour. Ice requirements depend on the inlet and exit temperatures of the carcass and the water, but 0.25 kg of ice per kg of carcass is usually adequate. However, *bacterial contamination* such as salmonella remains a concern with this method, and it may be necessary to chloride the water to control contamination.

*Tenderness* is an important consideration for poultry products just as it is for red meat, and preserving tenderness is an important consideration in the cooling and freezing of poultry. Birds cooked or frozen before passing through rigor mortis remain very tough. Natural tenderization begins soon after slaughter and is completed within 24 h when birds are held at  $4^{\circ}\text{C}$ .

**FIGURE 4-53**

Air chilling causes dehydration and thus weight loss for poultry, whereas immersion chilling causes a weight gain as a result of water absorption.

**FIGURE 4-54**

The storage life of fresh poultry decreases exponentially with increasing storage temperature.

Tenderization is rapid during the first three hours and slows down thereafter. Immersion in hot water and cutting into the muscle adversely affect tenderization. Increasing the *scalding temperature* or the scalding time has been observed to increase toughness, and decreasing the scalding time has been observed to increase tenderness. The *beating action* of mechanical feather-picking machines causes considerable toughening. Therefore, it is recommended that any cutting be done after tenderization. *Cutting up* the bird into pieces before natural tenderization is completed reduces tenderness considerably. Therefore, it is recommended that any cutting be done after tenderization. *Rapid chilling* of poultry can also have a toughening effect. It is found that the tenderization process can be speeded up considerably by a patented *electrical stunning* process.

Poultry products are *highly perishable*, and thus they should be kept at the *lowest* possible temperature to maximize their shelf life. Studies have shown that the populations of certain bacteria double every 36 h at  $-2^{\circ}\text{C}$ , 14 h at  $0^{\circ}\text{C}$ , 7 h at  $5^{\circ}\text{C}$ , and less than 1 h at  $25^{\circ}\text{C}$  (Fig. 4-54). Studies have also shown that the total bacterial counts on birds held at  $2^{\circ}\text{C}$  for 14 days are equivalent to those held at  $10^{\circ}\text{C}$  for 5 days or  $24^{\circ}\text{C}$  for 1 day. It has also been found that birds held at  $-1^{\circ}\text{C}$  had 8 days of additional shelf life over those held at  $4^{\circ}\text{C}$ .

The growth of microorganisms on the *surfaces* of the poultry causes the development of an *off-odor* and *bacterial slime*. The higher the initial amount of bacterial contamination, the faster the sliming occurs. Therefore, good sanitation practices during processing such as cleaning the equipment frequently and washing the carcasses are as important as the storage temperature in extending shelf life.

Poultry must be frozen *rapidly* to ensure a light, pleasing appearance. Poultry that is frozen slowly appears dark and develops large ice crystals that damage the tissue. The ice crystals formed during rapid freezing are small. Delaying freezing of poultry causes the ice crystals to become larger. Rapid freezing can be accomplished by forced air at temperatures of  $-23$  to  $-40^{\circ}\text{C}$  and velocities of 1.5 to 5 m/s in *air-blast tunnel freezers*. Most poultry is frozen this way. Also, the packaged birds freeze much faster on open shelves than they do in boxes. If poultry packages must be frozen in boxes, then it is very desirable to leave the boxes open or to cut holes on the boxes in the direction of airflow during freezing. For best results, the blast tunnel should be fully loaded across its cross-section with even spacing between the products to assure uniform airflow around all sides of the packages. The freezing time of poultry as a function of refrigerated air temperature is given in Figure 4-55. Thermal properties of poultry are given in Table 4-8.

Other freezing methods for poultry include sandwiching between *cold plates*, *immersion* into a refrigerated liquid such as glycol or calcium chloride brine, and *cryogenic cooling* with liquid nitrogen. Poultry can be frozen in several hours by cold plates. Very high freezing rates can be obtained by *immersing* the packaged birds into a low-temperature brine. The freezing time of birds in  $-29^{\circ}\text{C}$  brine can be as low as 20 min, depending on the size of the bird (Fig. 4-56). Also, immersion freezing produces a very appealing light appearance, and the high rates of heat transfer make

Note: Freezing time is the time required for temperature to fall from 0 to  $-4^{\circ}\text{C}$ . The values are for 2.3 to 3.6 kg chickens with initial temperature of 0 to  $2^{\circ}\text{C}$  and with air velocity of 2.3 to 2.8 m/s.

**FIGURE 4-55**

The variation of freezing time of poultry with air temperature.

**FIGURE 4-56**

The variation of temperature of the breast of 6.8-kg turkeys initially at 1°C with depth during immersion cooling at -29°C.

*From van der Berg and Lentz, 1958.*

continuous line operation feasible. It also has lower initial and maintenance costs than forced air, but *leaks* into the packages through some small holes or cracks remain a concern. The convection heat transfer coefficient is 17 W/m<sup>2</sup>·K for air at -29°C and 2.5 m/s whereas it is 170 W/m<sup>2</sup>·K for sodium chloride brine at -18°C and a velocity of 0.02 m/s. Sometimes liquid nitrogen is used to crust freeze the poultry products to -73°C. The freezing is then completed with air in a holding room at -23°C.

Properly packaged poultry products can be *stored* frozen for up to about a year at temperatures of -18°C or lower. The storage life drops considerably at higher (but still below-freezing) temperatures. Significant changes occur in flavor and juiciness when poultry is frozen for too long, and a stale rancid odor develops. Frozen poultry may become dehydrated and experience **freezer burn**, which may reduce the eye appeal of the product and cause toughening of the affected area. Dehydration and thus freezer burn can be controlled by *humidification*, *lowering* the storage temperature, and packaging the product in essentially *impermeable* film. The storage life can be extended by packing the poultry in an *oxygen-free* environment. The bacterial counts in precooked frozen products must be kept at safe levels since bacteria may not be destroyed completely during the reheating process at home.

Frozen poultry can be *thawed* in ambient air, water, refrigerator, or oven without any significant difference in taste. Big birds like turkey should be thawed safely by holding it in a refrigerator at 2 to 4°C for two to four days, depending on the size of the bird. They can also be thawed by immersing them into cool water in a large container for 4 to 6 h, or holding them in a paper bag. Care must be exercised to keep the bird's surface *cool* to minimize *microbiological growth* when thawing in air or water.

**TABLE 4-8**Thermal properties of poultry

| Quantity                         | Typical value                                     |

| Dark muscle                      | 1.557 at -40°C                                    |

**EXAMPLE 4-12 Chilling of Beef Carcasses in a Meat Plant**

The chilling room of a meat plant is  $18 \text{ m} \times 20 \text{ m} \times 5.5 \text{ m}$  in size and has a capacity of 450 beef carcasses. The power consumed by the fans and the lights of the chilling room are 26 and 3 kW, respectively, and the room gains heat through its envelope at a rate of 13 kW. The average mass of beef carcasses is 285 kg. The carcasses enter the chilling room at  $36^\circ\text{C}$  after they are washed to facilitate evaporative cooling and are cooled to  $15^\circ\text{C}$  in 10 h. The water is expected to evaporate at a rate of 0.080 kg/s. The air enters the evaporator section of the refrigeration system at  $0.7^\circ\text{C}$  and leaves at  $-2^\circ\text{C}$ . The air side of the evaporator is heavily finned, and the overall heat transfer coefficient of the evaporator based on the air side is  $20 \text{ W/m}^2\cdot\text{K}$ . Also, the average temperature difference between the air and the refrigerant in the evaporator is  $5.5^\circ\text{C}$ . Determine (a) the refrigeration load of the chilling room, (b) the volume flow rate of air, and (c) the heat transfer surface area of the evaporator on the air side, assuming all the vapor and the fog in the air freezes in the evaporator.

**FIGURE 4-57**

Schematic for Example 4-12.

**SOLUTION** The chilling room of a meat plant with a capacity of 450 beef carcasses is considered. The cooling load, the airflow rate, and the heat transfer area of the evaporator are to be determined.

**Assumptions** 1 Water evaporates at a rate of 0.080 kg/s. 2 All the moisture in the air freezes in the evaporator.

**Properties** The heat of fusion and the heat of vaporization of water at  $0^\circ\text{C}$  are 333.7 kJ/kg and 2501 kJ/kg (Table A-9). The density and specific heat of air at  $0^\circ\text{C}$  are  $1.292 \text{ kg/m}^3$  and  $1.006 \text{ kJ/kg}\cdot\text{K}$  (Table A-15). Also, the specific heat of beef carcass is determined from the relation in Table A-7b to be

$$c_p = 1.68 + 2.51 \times (\text{water content}) = 1.68 + 2.51 \times 0.58 = 3.14 \text{ kJ/kg}\cdot\text{K}$$

**Analysis** (a) A sketch of the chilling room is given in Figure 4-57. The amount of beef mass that needs to be cooled per unit time is

$$\begin{aligned} \dot{m}_{\text{beef}} &= (\text{Total beef mass cooled})/(\text{Cooling time}) \\ &= (450 \text{ carcasses})(285 \text{ kg/carcass})/(10 \times 3600 \text{ s}) = 3.56 \text{ kg/s} \end{aligned}$$

The product refrigeration load can be viewed as the energy that needs to be removed from the beef carcass as it is cooled from  $36$  to  $15^\circ\text{C}$  at a rate of 3.56 kg/s and is determined to be

$$\dot{Q}_{\text{beef}} = (\dot{m} c_p \Delta T)_{\text{beef}} = (3.56 \text{ kg/s})(3.14 \text{ kJ/kg}\cdot\text{K})(36 - 15)^\circ\text{C} = 235 \text{ kW}$$

Then the total refrigeration load of the chilling room becomes

$$\begin{aligned} \dot{Q}_{\text{total, chillroom}} &= \dot{Q}_{\text{beef}} + \dot{Q}_{\text{fan}} + \dot{Q}_{\text{lights}} + \dot{Q}_{\text{heat gain}} = 235 + 26 + 3 + 13 \\ &= 277 \text{ kW} \end{aligned}$$

The amount of carcass cooling due to evaporative cooling of water is

$$\dot{Q}_{\text{beef, evaporative}} = (\dot{m} h_{fg})_{\text{water}} = (0.080 \text{ kg/s})(2501 \text{ kJ/kg}) = 200 \text{ kW}$$

which is  $200/235 = 0.85 = 85$  percent of the total product cooling load. The remaining 15 percent of the heat is transferred by convection and radiation.

(b) Heat is transferred to air at the rate determined above, and the temperature of the air rises from  $-2^{\circ}\text{C}$  to  $0.7^{\circ}\text{C}$  as a result. Therefore, the mass flow rate of air is

$$\dot{m}_{\text{air}} = \frac{\dot{Q}_{\text{air}}}{(c_p \Delta T_{\text{air}})} = \frac{277 \text{ kW}}{(1.006 \text{ kJ/kg}\cdot\text{K})(0.7 - (-2)^{\circ}\text{C})} = 102.0 \text{ kg/s}$$

Then the volume flow rate of air becomes

$$\dot{V}_{\text{air}} = \frac{\dot{m}_{\text{air}}}{\rho_{\text{air}}} = \frac{102 \text{ kg/s}}{1.292 \text{ kg/m}^3} = 78.9 \text{ m}^3/\text{s}$$

(c) Normally the heat transfer load of the evaporator is the same as the refrigeration load. But in this case the water that enters the evaporator as a liquid is frozen as the temperature drops to  $-2^{\circ}\text{C}$ , and the evaporator must also remove the latent heat of freezing, which is determined from

$$\dot{Q}_{\text{freezing}} = (\dot{m} h_{\text{latent}})_{\text{water}} = (0.080 \text{ kg/s})(333.7 \text{ kJ/kg}) = 27 \text{ kW}$$

Therefore, the total rate of heat removal at the evaporator is

$$\dot{Q}_{\text{evaporator}} = \dot{Q}_{\text{total, chill room}} + \dot{Q}_{\text{freezing}} = 277 + 27 = 304 \text{ kW}$$

Then the heat transfer surface area of the evaporator on the air side is determined from  $\dot{Q}_{\text{evaporator}} = (UA)_{\text{air side}} \Delta T$ ,

$$A = \frac{\dot{Q}_{\text{evaporator}}}{U \Delta T} = \frac{304,000 \text{ W}}{(20 \text{ W/m}^2\cdot\text{K})(5.5^{\circ}\text{C})} = 2764 \text{ m}^2$$

Obviously, a finned surface must be used to provide such a large surface area on the air side.

## SUMMARY

In this chapter, we considered the variation of temperature with time as well as position in one- or multidimensional systems. We first considered the *lumped systems* in which the temperature varies with time but remains uniform throughout the system at any time. The temperature of a lumped body of arbitrary shape of mass  $m$ , volume  $V$ , surface area  $A_s$ , density  $\rho$ , and specific heat  $c_p$  initially at a uniform temperature  $T_i$  that is exposed to convection at time  $t = 0$  in a medium at temperature  $T_\infty$  with a heat transfer coefficient  $h$  is expressed as

$$\frac{T(t) - T_\infty}{T_i - T_\infty} = e^{-bt}$$

where

$$b = \frac{hA_s}{\rho c_p V} = \frac{h}{\rho c_p L_c}$$

is a positive quantity whose dimension is  $(\text{time})^{-1}$ . This relation can be used to determine the temperature  $T(t)$  of a body at time  $t$  or, alternatively, the time  $t$  required for the temperature to reach a specified value  $T(t)$ . Once the temperature  $T(t)$  at time  $t$  is available, the *rate* of convection heat transfer between the body and its environment at that time can be determined from Newton's law of cooling as

$$\dot{Q}(t) = hA_s[T(t) - T_\infty]$$

The *total amount* of heat transfer between the body and the surrounding medium over the time interval  $t = 0$  to  $t$  is simply the change in the energy content of the body,

$$Q = mc_p[T(t) - T_i]$$

The *maximum* heat transfer between the body and its surroundings is

$$Q_{\max} = mc_p(T_\infty - T_i)$$

The error involved in lumped system analysis is negligible when

$$\text{Bi} = \frac{hL_c}{k} < 0.1$$

where Bi is the *Biot number* and  $L_c = V/A_s$  is the *characteristic length*.

When the lumped system analysis is not applicable, the variation of temperature with position as well as time can be determined using the *transient temperature charts* given in Figs. 4–17, 4–18, 4–19, and 4–31 for a large plane wall, a long cylinder, a sphere, and a semi-infinite medium, respectively. These charts are applicable for one-dimensional heat transfer in those geometries. Therefore, their use is limited to situations in which the body is initially at a uniform temperature, all surfaces are subjected to the same thermal conditions, and the body does not involve any heat generation. These charts can also be used to determine the total heat transfer from the body up to a specified time  $t$ .

Using the *one-term approximation*, the solutions of one-dimensional transient heat conduction problems are expressed analytically as

$$\text{Plane wall: } \theta_{\text{wall}} = \frac{T(x, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \cos(\lambda_1 x/L)$$

$$\text{Cylinder: } \theta_{\text{cyl}} = \frac{T(r, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} J_0(\lambda_1 r/r_o)$$

$$\text{Sphere: } \theta_{\text{sph}} = \frac{T(r, t) - T_\infty}{T_i - T_\infty} = A_1 e^{-\lambda_1^2 \tau} \frac{\sin(\lambda_1 r/r_o)}{\lambda_1 r/r_o}$$

where the constants  $A_1$  and  $\lambda_1$  are functions of the Bi number only, and their values are listed in Table 4–2 against the Bi number for all three geometries. The error involved in one-term solutions is less than 2 percent when  $\tau > 0.2$ .

Using the one-term solutions, the fractional heat transfers in different geometries are expressed as

$$\text{Plane wall: } \left( \frac{Q}{Q_{\max}} \right)_{\text{wall}} = 1 - \theta_{0, \text{wall}} \frac{\sin \lambda_1}{\lambda_1}$$

$$\text{Cylinder: } \left( \frac{Q}{Q_{\max}} \right)_{\text{cyl}} = 1 - 2\theta_{0, \text{cyl}} \frac{J_1(\lambda_1)}{\lambda_1}$$

$$\text{Sphere: } \left( \frac{Q}{Q_{\max}} \right)_{\text{sph}} = 1 - 3\theta_{0, \text{sph}} \frac{\sin \lambda_1 - \lambda_1 \cos \lambda_1}{\lambda_1^3}$$

The solutions of transient heat conduction in a semi-infinite solid with constant properties under various boundary conditions at the surface are given as follows:

*Specified Surface Temperature,  $T_s = \text{constant}$ :*

$$\frac{T(x, t) - T_i}{T_s - T_i} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) \quad \text{and} \quad \dot{q}_s(t) = \frac{k(T_s - T_i)}{\sqrt{\pi \alpha t}}$$

*Specified Surface Heat Flux,  $\dot{q}_s = \text{constant}$ :*

$$T(x, t) - T_i = \frac{\dot{q}_s}{k} \left[ \sqrt{\frac{4\alpha t}{\pi}} \exp\left(-\frac{x^2}{4\alpha t}\right) - x \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) \right]$$

*Convection on the Surface,  $\dot{q}_s(t) = h[T_\infty - T(0, t)]$ :*

$$\begin{aligned} \frac{T(x, t) - T_i}{T_\infty - T_i} &= \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k} + \frac{h^2 \alpha t}{k^2}\right) \\ &\times \operatorname{erfc}\left(\frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k}\right) \end{aligned}$$

*Energy Pulse at Surface,  $e_s = \text{constant}$ :*

$$T(x, t) - T_i = \frac{e_s}{k\sqrt{\pi t/\alpha}} \exp\left(-\frac{x^2}{4\alpha t}\right)$$

where  $\operatorname{erfc}(\eta)$  is the *complementary error function* of argument  $\eta$ .

Using a superposition principle called the *product solution* these charts can also be used to construct solutions for the *two-dimensional* transient heat conduction problems encountered in geometries such as a short cylinder, a long rectangular bar, or a semi-infinite cylinder or plate, and even *three-dimensional* problems associated with geometries such as a rectangular prism or a semi-infinite rectangular bar, provided that all surfaces of the solid are subjected to convection to the same fluid at temperature  $T_\infty$  with the same convection heat transfer coefficient  $h$ , and the body involves no heat generation. The solution in such multidimensional geometries can be expressed as the product of the solutions for the one-dimensional geometries whose intersection is the multidimensional geometry.

The total heat transfer to or from a multidimensional geometry can also be determined by using the one-dimensional values. The transient heat transfer for a two-dimensional geometry formed by the intersection of two one-dimensional geometries 1 and 2 is

$$\left( \frac{Q}{Q_{\max}} \right)_{\text{total, 2D}} = \left( \frac{Q}{Q_{\max}} \right)_1 + \left( \frac{Q}{Q_{\max}} \right)_2 \left[ 1 - \left( \frac{Q}{Q_{\max}} \right)_1 \right].$$

Transient heat transfer for a three-dimensional body formed by the intersection of three one-dimensional bodies 1, 2, and 3 is given by

$$\begin{aligned} \left( \frac{Q}{Q_{\max}} \right)_{\text{total, 3D}} &= \left( \frac{Q}{Q_{\max}} \right)_1 + \left( \frac{Q}{Q_{\max}} \right)_2 \left[ 1 - \left( \frac{Q}{Q_{\max}} \right)_1 \right] \\ &+ \left( \frac{Q}{Q_{\max}} \right)_3 \left[ 1 - \left( \frac{Q}{Q_{\max}} \right)_1 \right] \left[ 1 - \left( \frac{Q}{Q_{\max}} \right)_2 \right] \end{aligned}$$

## PROBLEMS\*

**Lumped System Analysis**

**4–1C** What is the physical significance of the Biot number? Is the Biot number more likely to be larger for highly conducting solids or poorly conducting ones?

**4–2C** What is lumped system analysis? When is it applicable?

**4–3C** In what medium is the lumped system analysis more likely to be applicable: in water or in air? Why?

**4–4C** For which solid is the lumped system analysis more likely to be applicable: an actual apple or a golden apple of the same size? Why?

**4–5C** For which kind of bodies made of the same material is the lumped system analysis more likely to be applicable: slender ones or well-rounded ones of the same volume? Why?

**4–6C** Consider heat transfer between two identical hot solid bodies and the air surrounding them. The first solid is being cooled by a fan while the second one is allowed to cool naturally. For which solid is the lumped system analysis more likely to be applicable? Why?

**4–7C** Consider heat transfer between two identical hot solid bodies and their environments. The first solid is dropped in a large container filled with water, while the second one is allowed to cool naturally in the air. For which solid is the lumped system analysis more likely to be applicable? Why?

**4–8C** Consider a hot baked potato on a plate. The temperature of the potato is observed to drop by  $4^{\circ}\text{C}$  during the first minute. Will the temperature drop during the second minute be less than, equal to, or more than  $4^{\circ}\text{C}$ ? Why?

FIGURE P4–8C

**4–9C** Consider a potato being baked in an oven that is maintained at a constant temperature. The temperature of the potato is observed to rise by  $5^{\circ}\text{C}$  during the first minute. Will the temperature rise during the second minute be less than, equal to, or more than  $5^{\circ}\text{C}$ ? Why?

**4–10C** Consider two identical 4-kg pieces of roast beef. The first piece is baked as a whole, while the second is baked after being cut into two equal pieces in the same oven. Will there be any difference between the cooking times of the whole and cut roasts? Why?

\*Problems designated by a "C" are concept questions, and students are encouraged to answer them all. Problems designated by an "E" are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature, and are intended to be solved with an equation solver such as EES. Problems with the icon are Prevention through Design problems.

**4-11C** Consider a sphere and a cylinder of equal volume made of copper. Both the sphere and the cylinder are initially at the same temperature and are exposed to convection in the same environment. Which do you think will cool faster, the cylinder or the sphere? Why?

**4-12** Obtain relations for the characteristic lengths of a large plane wall of thickness  $2L$ , a very long cylinder of radius  $r_o$ , and a sphere of radius  $r_o$ .

**4-13** Obtain a relation for the time required for a lumped system to reach the average temperature  $\frac{1}{2}(T_i + T_\infty)$ , where  $T_i$  is the initial temperature and  $T_\infty$  is the temperature of the environment.

**4-14** A brick of  $203 \times 102 \times 57$  mm in dimension is being burned in a kiln to  $1100^\circ\text{C}$ , and then allowed to cool in a room with ambient air temperature of  $30^\circ\text{C}$  and convection heat transfer coefficient of  $5 \text{ W/m}^2\cdot\text{K}$ . If the brick has properties of  $\rho = 1920 \text{ kg/m}^3$ ,  $c_p = 790 \text{ J/kg}\cdot\text{K}$ , and  $k = 0.90 \text{ W/m}\cdot\text{K}$ , determine the time required to cool the brick to a temperature difference of  $5^\circ\text{C}$  from the ambient air temperature.

**4-15** Consider a 1000-W iron whose base plate is made of 0.5-cm-thick aluminum alloy 2024-T6 ( $\rho = 2770 \text{ kg/m}^3$ ,  $c_p = 875 \text{ J/kg}\cdot\text{K}$ ,  $\alpha = 7.3 \times 10^{-5} \text{ m}^2/\text{s}$ ). The base plate has a surface area of  $0.03 \text{ m}^2$ . Initially, the iron is in thermal equilibrium with the ambient air at  $22^\circ\text{C}$ . Taking the heat transfer coefficient at the surface of the base plate to be  $12 \text{ W/m}^2\cdot\text{K}$  and assuming 85 percent of the heat generated in the resistance wires is transferred to the plate, determine how long it will take for the plate temperature to reach  $140^\circ\text{C}$ . Is it realistic to assume the plate temperature to be uniform at all times?

FIGURE P4-15

**4-16** Reconsider Prob. 4-15. Using EES (or other) software, investigate the effects of the heat transfer coefficient and the final plate temperature on the time it will take for the plate to reach this temperature. Let the heat transfer coefficient vary from  $5 \text{ W/m}^2\cdot\text{K}$  to  $25 \text{ W/m}^2\cdot\text{K}$  and the temperature from  $30^\circ\text{C}$  to  $200^\circ\text{C}$ . Plot the time as functions of the heat transfer coefficient and the temperature, and discuss the results.

**4-17** Metal plates ( $k = 180 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg}\cdot\text{K}$ ) with a thickness of 1 cm are being heated in an oven for 2 minutes. Air in the oven is maintained at  $800^\circ\text{C}$  with a convection heat transfer coefficient of  $200 \text{ W/m}^2\cdot\text{K}$ . If the initial temperature of the plates is  $20^\circ\text{C}$ , determine the temperature of the plates when they are removed from the oven.

**4-18** A 5-mm-thick stainless steel strip ( $k = 21 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8000 \text{ kg/m}^3$ , and  $c_p = 570 \text{ J/kg}\cdot\text{K}$ ) is being heat treated as it moves through a furnace at a speed of 1 cm/s. The air temperature in the furnace is maintained at  $900^\circ\text{C}$  with a convection heat transfer coefficient of  $80 \text{ W/m}^2\cdot\text{K}$ . If the furnace length is 3 m and the stainless steel strip enters it at  $20^\circ\text{C}$ , determine the temperature of the strip as it exits the furnace.

FIGURE P4-18

**4-19** A batch of 2-cm-thick stainless steel plates ( $k = 21 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8000 \text{ kg/m}^3$ , and  $c_p = 570 \text{ J/kg}\cdot\text{K}$ ) are conveyed through a furnace to be heat treated. The plates enter the furnace at  $18^\circ\text{C}$ , and travel a distance of 3 m inside the furnace. The air temperature in the furnace is maintained at  $950^\circ\text{C}$  with a convection heat transfer coefficient of  $150 \text{ W/m}^2\cdot\text{K}$ . Using EES (or other) software, determine how the velocity of the plates affects the temperature of the plates at the end of the heat treatment. Let the velocity of the plates vary from 5 to 60 mm/s, and plot the temperature of the plates at the furnace exit as a function of the velocity.

FIGURE P4-19

**4-20** A 6-mm-thick stainless steel strip ( $k = 21 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8000 \text{ kg/m}^3$ , and  $c_p = 570 \text{ J/kg}\cdot\text{K}$ ) exiting an oven at a temperature of  $500^\circ\text{C}$  is allowed to cool within a buffer zone distance of 5 m. To prevent thermal burn to workers

who are handling the strip at the end of the buffer zone, the surface temperature of the strip should be cooled to 45°C. If the air temperature in the buffer zone is 15°C and the convection heat transfer coefficient is 120 W/m<sup>2</sup>·K, determine the maximum speed of the stainless steel strip.

**4-21**  After heat treatment, the 2-cm thick metal plates ( $k = 180 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg}\cdot\text{K}$ ) are conveyed through a cooling chamber with a length of 10 m. The plates enter the cooling chamber at an initial temperature of 500°C. The cooling chamber maintains a temperature of 10°C, and the convection heat transfer coefficient is given as a function of the air velocity blowing over the plates  $h = 33V^{0.8}$ , where  $h$  is in W/m<sup>2</sup>·K and  $V$  is in m/s. To prevent any incident of thermal burn, it is necessary for the plates to exit the cooling chamber at a temperature below 50°C. In designing the cooling process to meet this safety criteria, use the EES (or other) software to investigate the effect of the air velocity on the temperature of the plates at the exit of the cooling chamber. Let the air velocity vary from 0 to 40 m/s, and plot the temperatures of the plates exiting the cooling chamber as a function of air velocity at the moving plate speed of 2, 5, and 8 cm/s.

**4-22** A long copper rod of diameter 2.0 cm is initially at a uniform temperature of 100°C. It is now exposed to an air stream at 20°C with a heat transfer coefficient of 200 W/m<sup>2</sup>·K. How long would it take for the copper road to cool to an average temperature of 25°C?

**4-23** Springs in suspension system of automobiles are made of steel rods heated and wound into coils while ductile. Consider steel rods ( $\rho = 7832 \text{ kg/m}^3$ ,  $c_p = 434 \text{ J/kg}\cdot\text{K}$ , and  $k = 63.9 \text{ W/m}\cdot\text{K}$ ) with diameter of 2.5 cm and length of 1.27 m. The steel rods are heated in an oven with a uniform convection heat transfer coefficient of 20 W/m<sup>2</sup>·K. The steel rods were heated from an initial temperature of 20°C to the desired temperature of 450°C before being wound into coils. Determine the ambient temperature in the oven, if the steel rods were to be heated to the desired temperature within 10 minutes.

**4-24** Steel rods ( $\rho = 7832 \text{ kg/m}^3$ ,  $c_p = 434 \text{ J/kg}\cdot\text{K}$ , and  $k = 63.9 \text{ W/m}\cdot\text{K}$ ) are heated in a furnace to 850°C and then quenched in a water bath at 50°C for a period of 40 seconds as part of a hardening process. The convection heat transfer coefficient is 650 W/m<sup>2</sup>·K. If the steel rods have diameter of 40 mm and length of 2 m, determine their average temperature when they are taken out of the water bath.

**4-25** To warm up some milk for a baby, a mother pours milk into a thin-walled cylindrical container whose diameter is 6 cm. The height of the milk in the container is 7 cm. She then places the container into a large pan filled with hot water at 70°C. The milk is stirred constantly, so that its temperature is uniform at all times. If the heat transfer coefficient between the water and the container is 120 W/m<sup>2</sup>·K, determine how long it

will take for the milk to warm up from 3°C to 38°C. Assume the entire surface area of the cylindrical container (including the top and bottom) is in thermal contact with the hot water. Take the properties of the milk to be the same as those of water. Can the milk in this case be treated as a lumped system? Why? *Answer: 4.50 min*

**4-26** A person is found dead at 5PM in a room whose temperature is 20°C. The temperature of the body is measured to be 25°C when found, and the heat transfer coefficient is estimated to be 8 W/m<sup>2</sup>·K. Modeling the body as a 30-cm-diameter, 1.70-m-long cylinder and using the lumped system analysis as a rough approximation, estimate the time of death of that person.

**4-27** The temperature of a gas stream is to be measured by a thermocouple whose junction can be approximated as a 1.2-mm-diameter sphere. The properties of the junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ , and the heat transfer coefficient between the junction and the gas is  $h = 90 \text{ W/m}^2\cdot\text{K}$ . Determine how long it will take for the thermocouple to read 99 percent of the initial temperature difference. *Answer: 27.8 s*

**4-28** In an experiment, the temperature of a hot gas stream is to be measured by a thermocouple with a spherical junction. Due to the nature of this experiment, the response time of the thermocouple to register 99 percent of the initial temperature difference must be within 5 s. The properties of the thermocouple junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ . If the heat transfer coefficient between the thermocouple junction and the gas is 250 W/m<sup>2</sup>·K, determine the diameter of the junction.

**4-29** A thermocouple, with a spherical junction diameter of 0.5 mm, is used for measuring the temperature of hot air flow in a circular duct. The convection heat transfer coefficient of the air flow can be related with the diameter ( $D$ ) of the duct and the average air flow velocity ( $V$ ) as  $h = 2.2(V/D)^{0.5}$ , where  $D$ ,  $h$ , and  $V$  are in m, W/m<sup>2</sup>·K and m/s, respectively. The properties of the thermocouple junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ . Determine the minimum air flow velocity that the thermocouple can be used, if the maximum response time of the thermocouple to register 99 percent of the initial temperature difference is 5 s.

**FIGURE P4-29**

**4-30** Pulverized coal particles are used in oxy-fuel combustion power plants for electricity generation. Consider a situation where coal particles are suspended in hot air flowing through a heated tube, where the convection heat transfer coefficient is  $100 \text{ W/m}^2\cdot\text{K}$ . If the average surface area and volume of the coal particles are  $3.1 \text{ mm}^2$  and  $0.5 \text{ mm}^3$ , respectively, determine how much time it would take to heat the coal particles to two-thirds of the initial temperature difference.

**4-31** Oxy-fuel combustion power plants use pulverized coal particles as fuel to burn in a pure oxygen environment to generate electricity. Before entering the furnace, pulverized spherical coal particles with an average diameter of  $300 \mu\text{m}$ , are being transported at  $2 \text{ m/s}$  through a  $3\text{-m}$  long heated tube while suspended in hot air. The air temperature in the tube is  $900^\circ\text{C}$  and the average convection heat transfer coefficient is  $250 \text{ W/m}^2\cdot\text{K}$ . Determine the temperature of the coal particles at the exit of the heated tube, if the initial temperature of the particles is  $20^\circ\text{C}$ .

**4-32** Plasma spraying is a process used for coating a material surface with a protective layer to prevent the material from degradation. In a plasma spraying process, the protective layer in powder form is injected into a plasma jet. The powder is then heated to molten droplets and propelled onto the material surface. Once deposited on the material surface, the molten droplets solidify and form a layer of protective coating. Consider a plasma spraying process using alumina ( $k = 30 \text{ W/m}\cdot\text{K}$ ,  $\rho = 3970 \text{ kg/m}^3$ , and  $c_p = 800 \text{ J/kg}\cdot\text{K}$ ) powder that is injected into a plasma jet at  $T_\infty = 15,000^\circ\text{C}$  and  $h = 10,000 \text{ W/m}^2\cdot\text{K}$ . The alumina powder is made of particles that are spherical in shape with an average diameter of  $60 \mu\text{m}$  and a melting point at  $2300^\circ\text{C}$ . Determine the amount of time it would take for the particles, with an initial temperature of  $20^\circ\text{C}$ , to reach their melting point from the moment they are injected into the plasma jet.

**4-33** Consider a spherical shell satellite with outer diameter of  $4 \text{ m}$  and shell thickness of  $10 \text{ mm}$  is reentering the atmosphere. The shell satellite is made of stainless steel with properties of  $\rho = 8238 \text{ kg/m}^3$ ,  $c_p = 468 \text{ J/kg}\cdot\text{K}$ , and  $k = 13.4 \text{ W/m}\cdot\text{K}$ . During the reentry, the effective atmosphere temperature surrounding the satellite is  $1250^\circ\text{C}$  with convection heat transfer coefficient of  $130 \text{ W/m}^2\cdot\text{K}$ . If the initial temperature of the shell is  $10^\circ\text{C}$ , determine the shell temperature after 5 minutes of reentry. Assume heat transfer occurs only on the satellite shell.

**4-34** Carbon steel balls ( $\rho = 7833 \text{ kg/m}^3$ ,  $k = 54 \text{ W/m}\cdot\text{K}$ ,  $c_p = 0.465 \text{ kJ/kg}\cdot\text{C}$ , and  $\alpha = 1.474 \times 10^{-6} \text{ m}^2/\text{s}$ )  $8 \text{ mm}$  in diameter are annealed by heating them first to  $900^\circ\text{C}$  in a furnace and then allowing them to cool slowly to  $100^\circ\text{C}$  in ambient air at  $35^\circ\text{C}$ . If the average heat transfer coefficient is  $75 \text{ W/m}^2\cdot\text{K}$ , determine how long the annealing process will take. If 2500 balls are to be annealed per hour, determine the total rate of heat transfer from the balls to the ambient air.

FIGURE P4-34

**4-35** Reconsider Prob. 4-34. Using EES (or other) software, investigate the effect of the initial temperature of the balls on the annealing time and the total rate of heat transfer. Let the temperature vary from  $500^\circ\text{C}$  to  $1000^\circ\text{C}$ . Plot the time and the total rate of heat transfer as a function of the initial temperature, and discuss the results.

**4-36E** In a manufacturing facility, 2-in-diameter brass balls ( $k = 64.1 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ,  $\rho = 532 \text{ lbm/ft}^3$ , and  $c_p = 0.092 \text{ Btu/lbm}\cdot^\circ\text{F}$ ) initially at  $250^\circ\text{F}$  are quenched in a water bath at  $120^\circ\text{F}$  for a period of 2 min at a rate of 120 balls per minute. If the convection heat transfer coefficient is  $42 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ , determine (a) the temperature of the balls after quenching and (b) the rate at which heat needs to be removed from the water in order to keep its temperature constant at  $120^\circ\text{F}$ .

FIGURE P4-36E

**4-37** Consider a sphere of diameter  $5 \text{ cm}$ , a cube of side length  $5 \text{ cm}$ , and a rectangular prism of dimension  $4 \text{ cm} \times 5 \text{ cm} \times 6 \text{ cm}$ , all initially at  $0^\circ\text{C}$  and all made of silver ( $k = 429 \text{ W/m}\cdot\text{K}$ ,  $\rho = 10,500 \text{ kg/m}^3$ ,  $c_p = 0.235 \text{ kJ/kg}\cdot\text{K}$ ). Now all three of these geometries are exposed to ambient air at  $33^\circ\text{C}$  on all of their surfaces with a heat transfer coefficient of  $12 \text{ W/m}^2\cdot\text{K}$ . Determine how long it will take for the temperature of each geometry to rise to  $25^\circ\text{C}$ .

**4-38** An electronic device dissipating  $20 \text{ W}$  has a mass of  $20 \text{ g}$ , a specific heat of  $850 \text{ J/kg}\cdot\text{K}$ , and a surface area of  $4 \text{ cm}^2$ . The device is lightly used, and it is on for 5 min and then off for several hours, during which it cools to the ambient temperature of  $25^\circ\text{C}$ . Taking the heat transfer coefficient to be  $12 \text{ W/m}^2\cdot\text{K}$ , determine the temperature of the device at the end of the 5-min operating period. What would your answer be if the device were attached to an aluminum heat sink having a mass of  $200 \text{ g}$  and a surface area of  $80 \text{ cm}^2$ ? Assume the device and the heat sink to be nearly isothermal.

### Transient Heat Conduction in Large Plane Walls, Long Cylinders, and Spheres with Spatial Effects

**4-39C** An egg is to be cooked to a certain level of doneness by being dropped into boiling water. Can the cooking time be shortened by turning up the heat and bringing water to a more rapid boiling?

**4-40C** What is an infinitely long cylinder? When is it proper to treat an actual cylinder as being infinitely long, and when is it not? For example, is it proper to use this model when finding the temperatures near the bottom or top surfaces of a cylinder? Explain.

**4-41C** What is the physical significance of the Fourier number? Will the Fourier number for a specified heat transfer problem double when the time is doubled?

**4-42C** Why are the transient temperature charts prepared using nondimensionalized quantities such as the Biot and Fourier numbers instead of the actual variables such as thermal conductivity and time?

**4-43C** Can the transient temperature charts in Fig. 4-17 for a plane wall exposed to convection on both sides be used for a plane wall with one side exposed to convection while the other side is insulated? Explain.

**4-44C** How can we use the transient temperature charts when the surface temperature of the geometry is specified instead of the temperature of the surrounding medium and the convection heat transfer coefficient?

**4-45C** The Biot number during a heat transfer process between a sphere and its surroundings is determined to be 0.02. Would you use lumped system analysis or the transient temperature charts when determining the midpoint temperature of the sphere? Why?

**4-46C** A body at an initial temperature of  $T_i$  is brought into a medium at a constant temperature of  $T_\infty$ . How can you determine the maximum possible amount of heat transfer between the body and the surrounding medium?

**4-47** A hot brass plate is having its upper surface cooled by impinging jet of air at temperature of  $15^\circ\text{C}$  and convection

FIGURE P4-47

heat transfer coefficient of  $220 \text{ W/m}^2\cdot\text{K}$ . The 10-cm thick brass plate ( $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 380 \text{ J/kg}\cdot\text{K}$ ,  $k = 110 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$ ) has a uniform initial temperature of  $650^\circ\text{C}$ , and the bottom surface of the plate is insulated. Determine the temperature at the center plane of the brass plate after 3 minutes of cooling. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-48** In a meat processing plant, 2-cm-thick steaks ( $k = 0.45 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.91 \times 10^{-7} \text{ m}^2/\text{s}$ ) that are initially at  $25^\circ\text{C}$  are to be cooled by passing them through a refrigeration room at  $-11^\circ\text{C}$ . The heat transfer coefficient on both sides of the steaks is  $9 \text{ W/m}^2\cdot\text{K}$ . If both surfaces of the steaks are to be cooled to  $2^\circ\text{C}$ , determine how long the steaks should be kept in the refrigeration room. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-49** A 10-cm thick aluminum plate ( $\rho = 2702 \text{ kg/m}^3$ ,  $c_p = 903 \text{ J/kg}\cdot\text{K}$ ,  $k = 237 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 97.1 \times 10^{-6} \text{ m}^2/\text{s}$ ) is being heated in liquid with temperature of  $500^\circ\text{C}$ . The aluminum plate has a uniform initial temperature of  $25^\circ\text{C}$ . If the surface temperature of the aluminum plate is approximately the liquid temperature, determine the temperature at the center plane of the aluminum plate after 15 seconds of heating. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4-49

**4-50** In a production facility, 3-cm-thick large brass plates ( $k = 110 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 380 \text{ J/kg}\cdot\text{K}$ , and

FIGURE P4-50

$\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$ ) that are initially at a uniform temperature of 25°C are heated by passing them through an oven maintained at 700°C. The plates remain in the oven for a period of 10 min. Taking the convection heat transfer coefficient to be  $h = 80 \text{ W/m}^2\text{K}$ , determine the surface temperature of the plates when they come out of the oven. Solve this problem using analytical one-term approximation method (not the Heisler charts). Can this problem be solved using lumped system analysis? Justify your answer.

**4-51**  Reconsider Prob. 4-50. Using EES (or other) software, investigate the effects of the temperature of the oven and the heating time on the final surface temperature of the plates. Let the oven temperature vary from 500°C to 900°C and the time from 2 min to 30 min. Plot the surface temperature as the functions of the oven temperature and the time, and discuss the results.

**4-52** Layers of 23-cm-thick meat slabs ( $k = 0.47 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.13 \times 10^{-6} \text{ m}^2/\text{s}$ ) initially at a uniform temperature of 7°C are to be frozen by refrigerated air at -30°C flowing at a velocity of 1.4 m/s. The average heat transfer coefficient between the meat and the air is 20 W/m<sup>2</sup>K. Assuming the size of the meat slabs to be large relative to their thickness, determine how long it will take for the center temperature of the slabs to drop to -18°C. Also, determine the surface temperature of the meat slab at that time.

**4-53** In an annealing process, a 50-mm-thick stainless steel plate ( $\rho = 8238 \text{ kg/m}^3$ ,  $c_p = 468 \text{ J/kg}\cdot\text{K}$ ,  $k = 13.4 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 3.48 \times 10^{-6} \text{ m}^2/\text{s}$ ) was reheated in a furnace from an initial uniform temperature of 230°C. The ambient temperature inside the furnace is at a uniform temperature of 1000°C and has a convection heat transfer coefficient of 215 W/m<sup>2</sup>K. If the entire stainless steel plate is to be heated to at least 600°C, determine the time that the plate should be heated in the furnace using (a) Table 4-2 and (b) the Heisler chart (Figure 4-17).

**4-54** A heated 6-mm-thick Pyroceram plate ( $\rho = 2600 \text{ kg/m}^3$ ,  $c_p = 808 \text{ J/kg}\cdot\text{K}$ ,  $k = 3.98 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.89 \times 10^{-6} \text{ m}^2/\text{s}$ ) is being cooled in a room with air temperature of 25°C and convection heat transfer coefficient of 13.3 W/m<sup>2</sup>K. The heated Pyroceram plate had an initial temperature of 500°C, and is allowed to cool for 286 seconds. If the mass of the Pyroceram plate is 10 kg, determine the heat transfer from the Pyroceram plate during the cooling process using (a) Table 4-2 and (b) Figure 4-17.

**4-55E** Layers of 6-in-thick meat slabs ( $k = 0.26 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and  $\alpha = 1.4 \times 10^{-6} \text{ ft}^2/\text{s}$ ) initially at a uniform temperature of 50°F are cooled by refrigerated air at 23°F to a temperature of 36°F at their center in 12 h. Estimate the average heat transfer coefficient during this cooling process. Solve this problem using the Heisler charts. *Answer: 1.5 Btu/h·ft<sup>2</sup>·°F*

**4-56** A long cylindrical wood log ( $k = 0.17 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.28 \times 10^{-7} \text{ m}^2/\text{s}$ ) is 10 cm in diameter and is initially

at a uniform temperature of 15°C. It is exposed to hot gases at 550°C in a fireplace with a heat transfer coefficient of 13.6 W/m<sup>2</sup>K on the surface. If the ignition temperature of the wood is 420°C, determine how long it will be before the log ignites. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-57E** Long cylindrical AISI stainless steel rods ( $k = 7.74 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and  $\alpha = 0.135 \text{ ft}^2/\text{h}$ ) of 4-in-diameter are heat treated by drawing them at a velocity of 7 ft/min through a 21-ft-long oven maintained at 1700°F. The heat transfer coefficient in the oven is 20 Btu/h·ft<sup>2</sup>·°F. If the rods enter the oven at 70°F, determine their centerline temperature when they leave. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4-57E

**4-58** A long iron rod ( $\rho = 7870 \text{ kg/m}^3$ ,  $c_p = 447 \text{ J/kg}\cdot\text{K}$ ,  $k = 80.2 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 23.1 \times 10^{-6} \text{ m}^2/\text{s}$ ) with diameter of 25 mm is initially heated to a uniform temperature of 700°C. The iron rod is then quenched in a large water bath that is maintained at constant temperature of 50°C and convection heat transfer coefficient of 128 W/m<sup>2</sup>K. Determine the time required for the iron rod surface temperature to cool to 200°C. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4-58

**4-59** A 30-cm-diameter, 4-m-high cylindrical column of a house made of concrete ( $k = 0.79 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 5.94 \times 10^{-7} \text{ m}^2/\text{s}$ ,  $\rho = 1600 \text{ kg/m}^3$ , and  $c_p = 0.84 \text{ kJ/kg}\cdot\text{K}$ ) cooled to 14°C during a cold night is heated again during the day by being exposed

to ambient air at an average temperature of  $28^\circ\text{C}$  with an average heat transfer coefficient of  $14 \text{ W/m}^2\cdot\text{K}$ . Using analytical one-term approximation method (not the Heisler charts), determine (a) how long it will take for the column surface temperature to rise to  $27^\circ\text{C}$ , (b) the amount of heat transfer until the center temperature reaches to  $28^\circ\text{C}$ , and (c) the amount of heat transfer until the surface temperature reaches to  $27^\circ\text{C}$ .

**4–60** A long 35-cm-diameter cylindrical shaft made of stainless steel 304 ( $k = 14.9 \text{ W/m}\cdot\text{K}$ ,  $\rho = 7900 \text{ kg/m}^3$ ,  $c_p = 477 \text{ J/kg}\cdot\text{K}$ , and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$ ) comes out of an oven at a uniform temperature of  $400^\circ\text{C}$ . The shaft is then allowed to cool slowly in a chamber at  $150^\circ\text{C}$  with an average convection heat transfer coefficient of  $h = 60 \text{ W/m}^2\cdot\text{K}$ . Determine the temperature at the center of the shaft 20 min after the start of the cooling process. Also, determine the heat transfer per unit length of the shaft during this time period. Solve this problem using analytical one-term approximation method (not the Heisler charts). *Answers:  $390^\circ\text{C}$ , 15,900 kJ*

**4–61**  Reconsider Prob. 4–60. Using EES (or other) software, investigate the effect of the cooling time on the final center temperature of the shaft and the amount of heat transfer. Let the time vary from 5 min to 60 min. Plot the center temperature and the heat transfer as a function of the time, and discuss the results.

**4–62** A 2-cm-diameter plastic rod has a thermocouple inserted to measure temperature at the center of the rod. The plastic rod ( $\rho = 1190 \text{ kg/m}^3$ ,  $c_p = 1465 \text{ J/kg}\cdot\text{K}$ , and  $k = 0.19 \text{ W/m}\cdot\text{K}$ ) was initially heated to a uniform temperature of  $70^\circ\text{C}$ , and allowed to be cooled in ambient air temperature of  $25^\circ\text{C}$ . After 1388 s of cooling, the thermocouple measured the temperature at the center of the rod to be  $30^\circ\text{C}$ . Determine the convection heat transfer coefficient for this process. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4–62

**4–63** A 65-kg beef carcass ( $k = 0.47 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.13 \times 10^{-6} \text{ m}^2/\text{s}$ ) initially at a uniform temperature of  $37^\circ\text{C}$  is to be cooled by refrigerated air at  $-10^\circ\text{C}$  flowing at a velocity of  $1.2 \text{ m/s}$ . The average heat transfer coefficient between the carcass and the air is  $22 \text{ W/m}^2\cdot\text{K}$ . Treating the carcass as a cylinder of diameter 24 cm and height 1.4 m and disregarding heat transfer from the base and top surfaces, determine how long it will take for the center temperature of the carcass to drop to  $4^\circ\text{C}$ . Also, determine if any part of the carcass will freeze during this process. *Answer: 12.2 h*

FIGURE P4–63

**4–64** A long Pyroceram rod ( $\rho = 2600 \text{ kg/m}^3$ ,  $c_p = 808 \text{ J/kg}\cdot\text{K}$ ,  $k = 3.98 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.89 \times 10^{-6} \text{ m}^2/\text{s}$ ) with diameter of 10 mm has an initial uniform temperature of  $1000^\circ\text{C}$ . The Pyroceram rod is allowed to cool in ambient temperature of  $25^\circ\text{C}$  and convection heat transfer coefficient of  $80 \text{ W/m}^2\cdot\text{K}$ . If the Pyroceram rod is allowed to cool for 3 minutes, determine the temperature at the center of the rod using (a) Table 4–2 and (b) the Heisler chart (Figure 4–18).

**4–65** Steel rods, 2 m in length and 60 mm in diameter, are being drawn through an oven that maintains a temperature of  $800^\circ\text{C}$  and convection heat transfer coefficient of  $128 \text{ W/m}^2\cdot\text{K}$ . The steel rods ( $\rho = 7832 \text{ kg/m}^3$ ,  $c_p = 434 \text{ J/kg}\cdot\text{K}$ ,  $k = 63.9 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 18.8 \times 10^{-6} \text{ m}^2/\text{s}$ ) were initially in uniform temperature of  $30^\circ\text{C}$ . Using (a) Table 4–2 and (b) Figure 4–18, determine the amount of heat transferred to the steel rod after 133 s of heating.

**4–66** A father and son conducted the following simple experiment on a hot dog which measured 12.5 cm in length and 2.2 cm in diameter. They inserted one food thermometer into the midpoint of the hot dog and another one was placed just under the skin of the hot dog. The temperatures of the thermometers were monitored until both thermometers read  $20^\circ\text{C}$ , which is the ambient temperature. The hot dog was then placed in  $94^\circ\text{C}$  boiling water and after exactly 2 minutes they recorded the center temperature and the skin temperature of the hot dog to be  $59^\circ\text{C}$  and  $88^\circ\text{C}$ , respectively. Assuming the following properties for the hot dog:  $\rho = 980 \text{ kg/m}^3$  and  $c_p = 3900 \text{ J/kg}\cdot\text{K}$  and using transient temperature charts, determine (a) the thermal diffusivity of the hot dog, (b) the thermal conductivity of the hot dog, and (c) the convection heat transfer coefficient.

FIGURE P4–66

**4-67** An experiment is to be conducted to determine heat transfer coefficient on the surfaces of tomatoes that are placed in cold water at 7°C. The tomatoes ( $k = 0.59 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 0.141 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\rho = 999 \text{ kg/m}^3$ ,  $c_p = 3.99 \text{ kJ/kg}\cdot\text{K}$ ) with an initial uniform temperature of 30°C are spherical in shape with a diameter of 8 cm. After a period of 2 hours, the temperatures at the center and the surface of the tomatoes are measured to be 10.0°C and 7.1°C, respectively. Using analytical one-term approximation method (not the Heisler charts), determine the heat transfer coefficient and the amount of heat transfer during this period if there are eight such tomatoes in water.

**4-68** An ordinary egg can be approximated as a 5.5-cm-diameter sphere whose properties are roughly  $k = 0.6 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.14 \times 10^{-6} \text{ m}^2/\text{s}$ . The egg is initially at a uniform temperature of 8°C and is dropped into boiling water at 97°C. Taking the convection heat transfer coefficient to be  $h = 1400 \text{ W/m}^2\cdot\text{K}$ , determine how long it will take for the center of the egg to reach 70°C. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4-68

**4-69** Reconsider Prob. 4-68. Using EES (or other) software, investigate the effect of the final center temperature of the egg on the time it will take for the center to reach this temperature. Let the temperature vary from 50°C to 95°C. Plot the time versus the temperature, and discuss the results.

**4-70** For heat transfer purposes, an egg can be considered to be a 5.5-cm-diameter sphere having the properties of water. An egg that is initially at 8°C is dropped into the boiling water at 100°C. The heat transfer coefficient at the surface of the egg is estimated to be 800 W/m<sup>2</sup>·K. If the egg is considered cooked when its center temperature reaches 60°C, determine how long the egg should be kept in the boiling water. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-71** Citrus fruits are very susceptible to cold weather, and extended exposure to subfreezing temperatures can destroy them. Consider an 8-cm-diameter orange that is initially at 15°C. A cold front moves in one night, and the ambient temperature suddenly drops to -6°C, with a heat transfer coefficient of 15 W/m<sup>2</sup>·K. Using the properties of water for the orange and assuming the ambient conditions to remain constant for 4 h before the cold front moves out, determine if any part of the orange will freeze that night. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-72** A person puts a few apples into the freezer at -15°C to cool them quickly for guests who are about to arrive. Initially, the apples are at a uniform temperature of 20°C, and the heat transfer coefficient on the surfaces is 8 W/m<sup>2</sup>·K. Treating the apples as 9-cm-diameter spheres and taking their properties to be  $\rho = 840 \text{ kg/m}^3$ ,  $c_p = 3.81 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.418 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.3 \times 10^{-7} \text{ m}^2/\text{s}$ , determine the center and surface temperatures of the apples in 1 h. Also, determine the amount of heat transfer from each apple. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-73** Reconsider Prob. 4-72. Using EES (or other) software, investigate the effect of the initial temperature of the apples on the final center and surface temperatures and the amount of heat transfer. Let the initial temperature vary from 2°C to 30°C. Plot the center temperature, the surface temperature, and the amount of heat transfer as a function of the initial temperature, and discuss the results.

**4-74** A 9-cm-diameter potato ( $\rho = 1100 \text{ kg/m}^3$ ,  $c_p = 3900 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.6 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.4 \times 10^{-7} \text{ m}^2/\text{s}$ ) that is initially at a uniform temperature of 25°C is baked in an oven at 170°C until a temperature sensor inserted to the center of the potato indicates a reading of 70°C. The potato is then taken out of the oven and wrapped in thick towels so that almost no heat is lost from the baked potato. Assuming the heat transfer coefficient in the oven to be 40 W/m<sup>2</sup>·K, determine (a) how long the potato is baked in the oven and (b) the final equilibrium temperature of the potato after it is wrapped. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-75** Chickens with an average mass of 1.7 kg ( $k = 0.45 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.13 \times 10^{-6} \text{ m}^2/\text{s}$ ) initially at a uniform temperature of 15°C are to be chilled in agitated brine at -7°C. The average heat transfer coefficient between the chicken and the brine is determined experimentally to be 440 W/m<sup>2</sup>·K. Taking the average density of the chicken to be 0.95 g/cm<sup>3</sup> and treating the chicken as a spherical lump, determine the center and the surface temperatures of the chicken in 2 h and 45 min. Also, determine if any part of the chicken will freeze during this process. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-76** Hailstones are formed in high altitude clouds at 253 K. Consider a hailstone with diameter of 20 mm and is falling through air at 15°C with convection heat transfer coefficient of 163 W/m<sup>2</sup>·K. Assuming the hailstone can be modeled as a sphere and has properties of ice at 253 K, determine the duration it takes to reach melting point at the surface of the falling hailstone. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4-77** In *Betty Crocker's Cookbook*, it is stated that it takes 2 h 45 min to roast a 3.2-kg rib initially at 4.5°C "rare" in an oven maintained at 163°C. It is recommended that a meat thermometer be used to monitor the cooking, and the rib is considered rare done when the thermometer inserted into the center

of the thickest part of the meat registers 60°C. The rib can be treated as a homogeneous spherical object with the properties  $\rho = 1200 \text{ kg/m}^3$ ,  $c_p = 4.1 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.45 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 0.91 \times 10^{-7} \text{ m}^2/\text{s}$ . Determine (a) the heat transfer coefficient at the surface of the rib; (b) the temperature of the outer surface of the rib when it is done; and (c) the amount of heat transferred to the rib. (d) Using the values obtained, predict how long it will take to roast this rib to “medium” level, which occurs when the innermost temperature of the rib reaches 71°C. Compare your result to the listed value of 3 h 20 min.

If the roast rib is to be set on the counter for about 15 min before it is sliced, it is recommended that the rib be taken out of the oven when the thermometer registers about 4°C below the indicated value because the rib will continue cooking even after it is taken out of the oven. Do you agree with this recommendation? Solve this problem using analytical one-term approximation method (not the Heisler charts).

**Answers:** (a)  $156.9 \text{ W/m}^2\cdot\text{K}$ , (b)  $159.5^\circ\text{C}$ , (c)  $1629 \text{ kJ}$ , (d)  $3.0 \text{ h}$

**4-78** Repeat Prob. 4-77 for a roast rib that is to be “well-done” instead of “rare.” A rib is considered to be well-done when its center temperature reaches 77°C, and the roasting in this case takes about 4 h 15 min.

**4-79** White potatoes ( $k = 0.50 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.13 \times 10^{-6} \text{ m}^2/\text{s}$ ) that are initially at a uniform temperature of 25°C and have an average diameter of 6 cm are to be cooled by refrigerated air at 2°C flowing at a velocity of 4 m/s. The average heat transfer coefficient between the potatoes and the air is experimentally determined to be 19 W/m<sup>2</sup>·K. Determine how long it will take for the center temperature of the potatoes to drop to 6°C. Also, determine if any part of the potatoes will experience chilling injury during this process.

**FIGURE P4-79**

**4-80E** Oranges of 2.5-in-diameter ( $k = 0.26 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and  $\alpha = 1.4 \times 10^{-6} \text{ ft}^2/\text{s}$ ) initially at a uniform temperature of 78°F are to be cooled by refrigerated air at 25°F flowing at a velocity of 1 ft/s. The average heat transfer coefficient between the oranges and the air is experimentally determined to be 4.6 Btu/h·ft<sup>2</sup>·°F. Determine how long it will take for the center temperature of the oranges to drop to 40°F. Also, determine if any part of the oranges will freeze during this process.

**4-81E** In a chicken processing plant, whole chickens averaging 5 lbm each and initially at 65°F are to be cooled in the racks of a large refrigerator that is maintained at 5°F. The entire chicken is to be cooled below 45°F, but the temperature of the chicken is not to drop below 35°F at any point during refrigeration.

The convection heat transfer coefficient and thus the rate of heat transfer from the chicken can be controlled by varying the speed of a circulating fan inside. Determine the heat transfer coefficient that will enable us to meet both temperature constraints while keeping the refrigeration time to a minimum. The chicken can be treated as a homogeneous spherical object having the properties  $\rho = 74.9 \text{ lbm/ft}^3$ ,  $c_p = 0.98 \text{ Btu/lbm}\cdot^\circ\text{F}$ ,  $k = 0.26 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ , and  $\alpha = 0.0035 \text{ ft}^2/\text{h}$ . Solve this problem using the Heisler charts.

### Transient Heat Conduction in Semi-Infinite Solids

**4-82C** Under what conditions can a plane wall be treated as a semi-infinite medium?

**4-83C** What is a semi-infinite medium? Give examples of solid bodies that can be treated as semi-infinite mediums for heat transfer purposes.

**4-84C** Consider a hot semi-infinite solid at an initial temperature of  $T_i$  that is exposed to convection to a cooler medium at a constant temperature of  $T_\infty$ , with a heat transfer coefficient of  $h$ . Explain how you can determine the total amount of heat transfer from the solid up to a specified time  $t_o$ .

**4-85E** The walls of a furnace are made of 1.2-ft-thick concrete ( $k = 0.64 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and  $\alpha = 0.023 \text{ ft}^2/\text{h}$ ). Initially, the furnace and the surrounding air are in thermal equilibrium at 70°F. The furnace is then fired, and the inner surfaces of the furnace are subjected to hot gases at 1800°F with a very large heat transfer coefficient. Determine how long it will take for the temperature of the outer surface of the furnace walls to rise to 70.1°F. **Answer: 116 min**

**4-86** Consider a curing kiln whose walls are made of 30-cm-thick concrete with a thermal diffusivity of  $\alpha = 0.23 \times 10^{-5} \text{ m}^2/\text{s}$ . Initially, the kiln and its walls are in equilibrium with the surroundings at 6°C. Then all the doors are closed and the kiln is heated by steam so that the temperature of the inner surface of the walls is raised to 42°C and the temperature is maintained at that level for 2.5 h. The curing kiln is then opened and exposed to the atmospheric air after the steam flow is turned off. If the outer surfaces of the walls of the kiln were insulated, would it save any energy that day during the period the kiln was used for curing for 2.5 h only, or would it make no difference? Base your answer on calculations.

**FIGURE P4-86**

**4-87** In areas where the air temperature remains below 0°C for prolonged periods of time, the freezing of water in underground pipes is a major concern. Fortunately, the soil remains relatively warm during those periods, and it takes weeks for the subfreezing temperatures to reach the water mains in the ground. Thus, the soil effectively serves as an insulation to protect the water from the freezing atmospheric temperatures in winter.

The ground at a particular location is covered with snow pack at  $-8^{\circ}\text{C}$  for a continuous period of 60 days, and the average soil properties at that location are  $k = 0.35 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$ . Assuming an initial uniform temperature of  $8^{\circ}\text{C}$  for the ground, determine the minimum burial depth to prevent the water pipes from freezing.

**4-88** A large cast iron container ( $k = 52 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.70 \times 10^{-5} \text{ m}^2/\text{s}$ ) with 5-cm-thick walls is initially at a uniform temperature of  $0^{\circ}\text{C}$  and is filled with ice at  $0^{\circ}\text{C}$ . Now the outer surfaces of the container are exposed to hot water at  $60^{\circ}\text{C}$  with a very large heat transfer coefficient. Determine how long it will be before the ice inside the container starts melting. Also, taking the heat transfer coefficient on the inner surface of the container to be  $250 \text{ W/m}^2\cdot\text{K}$ , determine the rate of heat transfer to the ice through a 1.2-m-wide and 2-m-high section of the wall when steady operating conditions are reached. Assume the ice starts melting when its inner surface temperature rises to  $0.1^{\circ}\text{C}$ .

FIGURE P4–88

**4-89** A highway made of asphalt is initially at a uniform temperature of  $55^{\circ}\text{C}$ . Suddenly the highway surface temperature is reduced to  $25^{\circ}\text{C}$  by rain. Determine the temperature at the depth of 3 cm from the highway surface and the heat flux transferred from the highway after 60 minutes. Assume the highway surface temperature is maintained at  $25^{\circ}\text{C}$ . *Answers: 53.6°C, 98 W/m<sup>2</sup>*

**4-90** A thick aluminum block initially at  $20^{\circ}\text{C}$  is subjected to constant heat flux of  $4000 \text{ W/m}^2$  by an electric resistance heater whose top surface is insulated. Determine how much the surface temperature of the block will rise after 30 minutes.

**4-91** Refractory bricks are used as linings for furnaces, and they generally have low thermal conductivity to minimize heat loss through the furnace walls. Consider a thick furnace wall lining with refractory bricks ( $k = 1.0 \text{ W/m}\cdot\text{K}$  and  $\alpha = 5.08 \times 10^{-7} \text{ m}^2/\text{s}$ ),

where initially the wall has a uniform temperature of  $15^{\circ}\text{C}$ . If the wall surface is subjected to uniform heat flux of  $20 \text{ kW/m}^2$ , determine the temperature at the depth of 10 cm from the surface after an hour of heating time.

FIGURE P4–91

**4-92** A thick wall made of refractory bricks ( $k = 1.0 \text{ W/m}\cdot\text{K}$  and  $\alpha = 5.08 \times 10^{-7} \text{ m}^2/\text{s}$ ) has a uniform initial temperature of  $15^{\circ}\text{C}$ . The wall surface is subjected to uniform heat flux of  $20 \text{ kW/m}^2$ . Using EES (or other) software, investigate the effect of heating time on the temperature at the wall surface and at  $x = 1 \text{ cm}$  and  $x = 5 \text{ cm}$  from the surface. Let the heating time vary from 10 to 3600 s, and plot the temperatures at  $x = 0, 1$ , and  $5 \text{ cm}$  from the wall surface as a function of heating time.

**4-93** A stainless steel slab ( $k = 14.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$ ) and a copper slab ( $k = 401 \text{ W/m}\cdot\text{K}$  and  $\alpha = 117 \times 10^{-6} \text{ m}^2/\text{s}$ ) are subjected to uniform heat flux of  $10 \text{ kW/m}^2$  at the surface. Both slabs have a uniform initial temperature of  $20^{\circ}\text{C}$ . Using EES (or other) software, investigate the effect of time on the temperatures of both materials at the depth of 8 cm from the surface. By varying the time of exposure to the heat flux from 5 to 300 s, plot the temperatures at a depth of  $x = 8 \text{ cm}$  from the surface as a function of time.

**4-94** Thick slabs of stainless steel ( $k = 14.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$ ) and copper ( $k = 401 \text{ W/m}\cdot\text{K}$  and  $\alpha = 117 \times 10^{-6} \text{ m}^2/\text{s}$ ) are subjected to uniform heat flux of  $8 \text{ kW/m}^2$  at the surface. The two slabs have a uniform initial temperature of  $20^{\circ}\text{C}$ . Determine the temperatures of both slabs, at 1 cm from the surface, after 60 s of exposure to the heat flux.

FIGURE P4–94

**4–95** A thick wood slab ( $k = 0.17 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.28 \times 10^{-7} \text{ m}^2/\text{s}$ ) that is initially at a uniform temperature of  $25^\circ\text{C}$  is exposed to hot gases at  $550^\circ\text{C}$  for a period of 5 min. The heat transfer coefficient between the gases and the wood slab is  $35 \text{ W/m}^2\cdot\text{K}$ . If the ignition temperature of the wood is  $450^\circ\text{C}$ , determine if the wood will ignite.

**4–96** The soil temperature in the upper layers of the earth varies with the variations in the atmospheric conditions. Before a cold front moves in, the earth at a location is initially at a uniform temperature of  $10^\circ\text{C}$ . Then the area is subjected to a temperature of  $-10^\circ\text{C}$  and high winds that resulted in a convection heat transfer coefficient of  $40 \text{ W/m}^2\cdot\text{K}$  on the earth's surface for a period of 10 h. Taking the properties of the soil at that location to be  $k = 0.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.6 \times 10^{-5} \text{ m}^2/\text{s}$ , determine the soil temperature at distances 0, 10, 20, and 50 cm from the earth's surface at the end of this 10-h period.

FIGURE P4–96

**4–97** Reconsider Prob. 4–96. Using EES (or other) software, plot the soil temperature as a function of the distance from the earth's surface as the distance varies from 0 m to 1 m, and discuss the results.

**4–98** We often cut a watermelon in half and put it into the freezer to cool it quickly. But usually we forget to check on it and end up having a watermelon with a frozen layer on the top. To avoid this potential problem a person wants to set the timer such that it will go off when the temperature of the exposed surface of the watermelon drops to  $3^\circ\text{C}$ . Consider a 25-cm-diameter spherical watermelon that is cut into two equal parts and put into a freezer at  $-12^\circ\text{C}$ . Initially, the entire watermelon is at a uniform temperature of  $25^\circ\text{C}$ , and the heat transfer coefficient on the surfaces is  $22 \text{ W/m}^2\cdot\text{K}$ . Assuming the watermelon to have the properties of water, determine how long it will take for the center of the exposed cut surfaces of the watermelon to drop to  $3^\circ\text{C}$ .

**4–99** In a vacuum chamber, a thick slab is placed under an array of laser diodes with an output constant pulse. A thermocouple is inserted inside the slab at 25 mm from the surface and the slab has an initial uniform temperature of  $20^\circ\text{C}$ . The known properties of the slab are  $k = 63.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 18.8 \times 10^{-6} \text{ m}^2/\text{s}$ . If the thermocouple measured a temperature of  $130^\circ\text{C}$  after 30 s the slab surface has been exposed to the laser pulse, determine (a) the amount of energy per unit surface area directed on the slab surface and (b) the thermocouple reading after 60 s has elapsed.

FIGURE P4–99

**4–100** Thick slabs of stainless steel ( $k = 14.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$ ) and copper ( $k = 401 \text{ W/m}\cdot\text{K}$  and  $\alpha = 117 \times 10^{-6} \text{ m}^2/\text{s}$ ) are placed under an array of laser diodes, which supply an energy pulse of  $5 \times 10^7 \text{ J/m}^2$  instantaneously at  $t = 0$  to both materials. The two slabs have a uniform initial temperature of  $20^\circ\text{C}$ . Determine the temperatures of both slabs, at 5 cm from the surface and 60 s after receiving an energy pulse from the laser diodes.

FIGURE P4–100

**4–101** A stainless steel slab ( $k = 14.9 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.95 \times 10^{-6} \text{ m}^2/\text{s}$ ) and a copper slab ( $k = 401 \text{ W/m}\cdot\text{K}$  and  $\alpha = 117 \times 10^{-6} \text{ m}^2/\text{s}$ ) are placed under an array of laser diodes, which supply an energy pulse of  $5 \times 10^7 \text{ J/m}^2$  instantaneously at  $t = 0$  to both materials. The two slabs have a uniform initial temperature of  $20^\circ\text{C}$ . Using EES (or other) software, investigate the effect of time on the temperatures of both materials at the depth of 5 cm from the surface. By varying the time from 1 to 80 s after the slabs have received the energy pulse, plot the temperatures at 5 cm from the surface as a function of time.

**4–102** A bare-footed person whose feet are at  $32^\circ\text{C}$  steps on a large aluminum block at  $20^\circ\text{C}$ . Treating both the feet and the aluminum block as semi-infinite solids, determine the contact surface temperature. What would your answer be if the person stepped on a wood block instead? At room temperature, the  $\sqrt{kpc_p}$  value is  $24 \text{ kJ/m}^2\cdot^\circ\text{C}$  for aluminum,  $0.38 \text{ kJ/m}^2\cdot^\circ\text{C}$  for wood, and  $1.1 \text{ kJ/m}^2\cdot^\circ\text{C}$  for human flesh.

### Transient Heat Conduction in Multidimensional Systems

**4–103C** What is the product solution method? How is it used to determine the transient temperature distribution in a two-dimensional system?

**4–104C** How is the product solution used to determine the variation of temperature with time and position in three-dimensional systems?

**4–105C** A short cylinder initially at a uniform temperature  $T_i$  is subjected to convection from all of its surfaces to a medium at temperature  $T_\infty$ . Explain how you can determine the temperature of the midpoint of the cylinder at a specified time  $t$ .

**4-106C** Consider a short cylinder whose top and bottom surfaces are insulated. The cylinder is initially at a uniform temperature  $T_i$  and is subjected to convection from its side surface to a medium at temperature  $T_\infty$  with a heat transfer coefficient of  $h$ . Is the heat transfer in this short cylinder one- or two-dimensional? Explain.

**4-107** Consider a cubic block whose sides are 5 cm long and a cylindrical block whose height and diameter are also 5 cm. Both blocks are initially at  $20^\circ\text{C}$  and are made of granite ( $k = 2.5 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.15 \times 10^{-6} \text{ m}^2/\text{s}$ ). Now both blocks are exposed to hot gases at  $500^\circ\text{C}$  in a furnace on all of their surfaces with a heat transfer coefficient of  $40 \text{ W/m}^2\cdot\text{K}$ . Determine the center temperature of each geometry after 10, 20, and 60 min.

FIGURE P4-107

**4-108** Repeat Prob. 4-107 with the heat transfer coefficient at the top and the bottom surfaces of each block being doubled to  $80 \text{ W/m}^2\cdot\text{K}$ .

**4-109E** A hot dog can be considered to be a cylinder 5 in long and 0.8 in in diameter whose properties are  $\rho = 61.2 \text{ lbm/ft}^3$ ,  $c_p = 0.93 \text{ Btu/lbm}\cdot^\circ\text{F}$ ,  $k = 0.44 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ , and  $\alpha = 0.0077 \text{ ft}^2/\text{h}$ . A hot dog initially at  $40^\circ\text{F}$  is dropped into boiling water at  $212^\circ\text{F}$ . If the heat transfer coefficient at the surface of the hot dog is estimated to be  $120 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ , determine the center temperature of the hot dog after 5, 10, and 15 min by treating the hot dog as (a) a finite cylinder and (b) an infinitely long cylinder.

**4-110** A 5-cm-high rectangular ice block ( $k = 2.22 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.124 \times 10^{-7} \text{ m}^2/\text{s}$ ) initially at  $-20^\circ\text{C}$  is placed on a

FIGURE P4-110

table on its square base  $4 \text{ cm} \times 4 \text{ cm}$  in a room at  $18^\circ\text{C}$ . The heat transfer coefficient on the exposed surfaces of the ice block is  $12 \text{ W/m}^2\cdot\text{K}$ . Disregarding any heat transfer from the base to the table, determine how long it will be before the ice block starts melting. Where on the ice block will the first liquid droplets appear?

**4-111** Reconsider Prob. 4-110. Using EES (or other) software, investigate the effect of the initial temperature of the ice block on the time period before the ice block starts melting. Let the initial temperature vary from  $-26^\circ\text{C}$  to  $-4^\circ\text{C}$ . Plot the time versus the initial temperature, and discuss the results.

**4-112** A 2-cm-high cylindrical ice block ( $k = 2.22 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.124 \times 10^{-7} \text{ m}^2/\text{s}$ ) is placed on a table on its base of diameter 2 cm in a room at  $24^\circ\text{C}$ . The heat transfer coefficient on the exposed surfaces of the ice block is  $13 \text{ W/m}^2\cdot\text{K}$ , and heat transfer from the base of the ice block to the table is negligible. If the ice block is not to start melting at any point for at least 3 h, determine what the initial temperature of the ice block should be.

**4-113** A short brass cylinder ( $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 0.389 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 110 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 3.39 \times 10^{-5} \text{ m}^2/\text{s}$ ) of diameter 8 cm and height 15 cm is initially at a uniform temperature of  $150^\circ\text{C}$ . The cylinder is now placed in atmospheric air at  $20^\circ\text{C}$ , where heat transfer takes place by convection with a heat transfer coefficient of  $40 \text{ W/m}^2\cdot\text{K}$ . Calculate (a) the center temperature of the cylinder; (b) the center temperature of the top surface of the cylinder; and (c) the total heat transfer from the cylinder 15 min after the start of the cooling.

FIGURE P4-113

**4-114** Reconsider Prob. 4-113. Using EES (or other) software, investigate the effect of the cooling time on the center temperature of the cylinder, the center temperature of the top surface of the cylinder, and the total heat transfer. Let the time vary from 5 min to 60 min. Plot the center temperature of the cylinder, the center temperature of the top surface, and the total heat transfer as a function of the time, and discuss the results.

**4–115** A semi-infinite aluminum cylinder ( $k = 237 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 9.71 \times 10^{-5} \text{ m}^2/\text{s}$ ) of diameter  $D = 15 \text{ cm}$  is initially at a uniform temperature of  $T_i = 115^\circ\text{C}$ . The cylinder is now placed in water at  $10^\circ\text{C}$ , where heat transfer takes place by convection with a heat transfer coefficient of  $h = 140 \text{ W/m}^2\cdot\text{K}$ . Determine the temperature at the center of the cylinder 5 cm from the end surface 8 min after the start of cooling.

**4–116** A 20-cm-long cylindrical aluminum block ( $\rho = 2702 \text{ kg/m}^3$ ,  $c_p = 0.896 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 236 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 9.75 \times 10^{-5} \text{ m}^2/\text{s}$ ), 15 cm in diameter, is initially at a uniform temperature of  $20^\circ\text{C}$ . The block is to be heated in a furnace at  $1200^\circ\text{C}$  until its center temperature rises to  $300^\circ\text{C}$ . If the heat transfer coefficient on all surfaces of the block is  $80 \text{ W/m}^2\cdot\text{K}$ , determine how long the block should be kept in the furnace. Also, determine the amount of heat transfer from the aluminum block if it is allowed to cool in the room until its temperature drops to  $20^\circ\text{C}$  throughout.

**4–117** Repeat Prob. 4–116 for the case where the aluminum block is inserted into the furnace on a low-conductivity material so that the heat transfer to or from the bottom surface of the block is negligible.

**4–118**  Reconsider Prob. 4–116. Using EES (or other) software, investigate the effect of the final center temperature of the block on the heating time and the amount of heat transfer. Let the final center temperature vary from  $50^\circ\text{C}$  to  $1000^\circ\text{C}$ . Plot the time and the heat transfer as a function of the final center temperature, and discuss the results.

### Special Topic: Refrigeration and Freezing of Foods

**4–119C** What are the common kinds of microorganisms? What undesirable changes do microorganisms cause in foods?

**4–120C** How does refrigeration prevent or delay the spoilage of foods? Why does freezing extend the storage life of foods for months?

**4–121C** What are the environmental factors that affect the growth rate of microorganisms in foods?

**4–122C** What is the effect of cooking on the microorganisms in foods? Why is it important that the internal temperature of a roast in an oven be raised above  $70^\circ\text{C}$ ?

**4–123C** How can the contamination of foods with microorganisms be prevented or minimized? How can the growth of microorganisms in foods be retarded? How can the microorganisms in foods be destroyed?

**4–124C** How does (a) the air motion and (b) the relative humidity of the environment affect the growth of microorganisms in foods?

**4–125C** The cooling of a beef carcass from  $37^\circ\text{C}$  to  $5^\circ\text{C}$  with refrigerated air at  $0^\circ\text{C}$  in a chilling room takes about 48 h. To reduce the cooling time, it is proposed to cool the carcass with refrigerated air at  $-10^\circ\text{C}$ . How would you evaluate this proposal?

**4–126C** Consider the freezing of packaged meat in boxes with refrigerated air. How do (a) the temperature of air, (b) the velocity of air, (c) the capacity of the refrigeration system, and (d) the size of the meat boxes affect the freezing time?

**4–127C** How does the rate of freezing affect the tenderness, color, and the drip of meat during thawing?

**4–128C** It is claimed that beef can be stored for up to two years at  $-23^\circ\text{C}$  but no more than one year at  $-12^\circ\text{C}$ . Is this claim reasonable? Explain.

**4–129C** What is a refrigerated shipping dock? How does it reduce the refrigeration load of the cold storage rooms?

**4–130C** How does immersion chilling of poultry compare to forced-air chilling with respect to (a) cooling time, (b) moisture loss of poultry, and (c) microbial growth.

**4–131C** What is the proper storage temperature of frozen poultry? What are the primary methods of freezing for poultry?

**4–132C** What are the factors that affect the quality of frozen fish?

**4–133** The chilling room of a meat plant is  $15 \text{ m} \times 18 \text{ m} \times 5.5 \text{ m}$  in size and has a capacity of 350 beef carcasses. The power consumed by the fans and the lights in the chilling room are 22 and 2 kW, respectively, and the room gains heat through its envelope at a rate of 14 kW. The average mass of beef carcasses is 220 kg. The carcasses enter the chilling room at  $35^\circ\text{C}$ , after they are washed to facilitate evaporative cooling, and are cooled to  $16^\circ\text{C}$  in 12 h. The air enters the chilling room at  $-2.2^\circ\text{C}$  and leaves at  $0.5^\circ\text{C}$ . Determine (a) the refrigeration load of the chilling room and (b) the volume flow rate of air. The average specific heats of beef carcasses and air are 3.14 and  $1.0 \text{ kJ/kg}\cdot\text{C}$ , respectively, and the density of air can be taken to be  $1.28 \text{ kg/m}^3$ .

**4–134** In a meat processing plant, 10-cm-thick beef slabs ( $\rho = 1090 \text{ kg/m}^3$ ,  $c_p = 3.54 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.47 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 0.13 \times 10^{-6} \text{ m}^2/\text{s}$ ) initially at  $15^\circ\text{C}$  are to be cooled in the racks of a large freezer that is maintained at  $-12^\circ\text{C}$ . The meat slabs are placed close to each other so that heat transfer from the 10-cm-thick edges is negligible. The entire slab is to be cooled below  $5^\circ\text{C}$ , but the temperature of the steak is not

**FIGURE P4–134**

to drop below  $-1^\circ\text{C}$  anywhere during refrigeration to avoid “frost bite.” The convection heat transfer coefficient and thus the rate of heat transfer from the steak can be controlled by varying the speed of a circulating fan inside. Determine the

heat transfer coefficient  $h$  that will enable us to meet both temperature constraints while keeping the refrigeration time to a minimum. *Answer: 9.9 W/m<sup>2</sup>·K*

**4-135** Chickens with an average mass of 2.2 kg and average specific heat of 3.54 kJ/kg·°C are to be cooled by chilled water that enters a continuous-flow-type immersion chiller at 0.5°C. Chickens are dropped into the chiller at a uniform temperature of 15°C at a rate of 500 chickens per hour and are cooled to an average temperature of 3°C before they are taken out. The chiller gains heat from the surroundings at a rate of 210 kJ/min. Determine (a) the rate of heat removal from the chicken, in kW, and (b) the mass flow rate of water, in kg/s, if the temperature rise of water is not to exceed 2°C.

**4-136E** Chickens with a water content of 74 percent, an initial temperature of 32°F, and a mass of about 7.5 lbm are to be frozen by refrigerated air at -40°F. Using Figure 4-55, determine how long it will take to reduce the inner surface temperature of chickens to 25°F. What would your answer be if the air temperature were -80°F?

**4-137** Turkeys with a water content of 64 percent that are initially at 1°C and have a mass of about 7 kg are to be frozen by submerging them into brine at -29°C. Using Figure 4-56, determine how long it will take to reduce the temperature of the turkey breast at a depth of 3.8 cm to -18°C. If the temperature at a depth of 3.8 cm in the breast represents the average temperature of the turkey, determine the amount of heat transfer per turkey assuming (a) the entire water content of the turkey is frozen and (b) only 90 percent of the water content of the turkey is frozen at -18°C. Take the specific heats of turkey to be 2.98 and 1.65 kJ/kg·°C above and below the freezing point of -2.8°C, respectively, and the latent heat of fusion of turkey to be 214 kJ/kg. *Answers: (a) 1753 kJ, (b) 1617 kJ*

FIGURE P4-137

### Review Problems

**4-138** A long roll of 2-m-wide and 0.5-cm-thick 1-Mn manganese steel plate coming off a furnace at 820°C is to be quenched in an oil bath ( $c_p = 2.0 \text{ kJ/kg}\cdot\text{K}$ ) at 45°C. The metal sheet is moving at a steady velocity of 15 m/min, and the oil bath is 9 m long. Taking the convection heat transfer coefficient on both sides of the plate to be 860 W/m<sup>2</sup>·K, determine the temperature of the sheet metal when it leaves the oil bath.

Also, determine the required rate of heat removal from the oil to keep its temperature constant at 45°C.

FIGURE P4-138

**4-139** Large steel plates 1.0-cm in thickness are quenched from 600°C to 100°C by submerging them in an oil reservoir held at 30°C. The average heat transfer coefficient for both faces of steel plates is 400 W/m<sup>2</sup>·K. Average steel properties are  $k = 45 \text{ W/m}\cdot\text{K}$ ,  $\rho = 7800 \text{ kg/m}^3$ , and  $c_p = 470 \text{ J/kg}\cdot\text{K}$ . Calculate the quench time for steel plates.

**4-140** Long aluminum wires of diameter 3 mm ( $\rho = 2702 \text{ kg/m}^3$ ,  $c_p = 0.896 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 236 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 9.75 \times 10^{-5} \text{ m}^2/\text{s}$ ) are extruded at a temperature of 350°C and exposed to atmospheric air at 30°C with a heat transfer coefficient of 35 W/m<sup>2</sup>·K. (a) Determine how long it will take for the wire temperature to drop to 50°C. (b) If the wire is extruded at a velocity of 10 m/min, determine how far the wire travels after extrusion by the time its temperature drops to 50°C. What change in the cooling process would you propose to shorten this distance? (c) Assuming the aluminum wire leaves the extrusion room at 50°C, determine the rate of heat transfer from the wire to the extrusion room. *Answers: (a) 144 s, (b) 24 m, (c) 856 W*

FIGURE P4-140

**4-141** Repeat Prob. 4-140 for a copper wire ( $\rho = 8950 \text{ kg/m}^3$ ,  $c_p = 0.383 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 386 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.13 \times 10^{-4} \text{ m}^2/\text{s}$ ).

**4-142** Aluminum wires, 3 mm in diameter, are produced by extrusion. The wires leave the extruder at an average temperature of 350°C and at a linear rate of 10 m/min. Before leaving the extrusion room, the wires are cooled to an average temperature of 50°C by transferring heat to the surrounding air at 25°C with a heat transfer coefficient of 50 W/m<sup>2</sup>·K. Calculate the necessary length of the wire cooling section in the extrusion room.

**4-143E** During a picnic on a hot summer day, the only available drinks were those at the ambient temperature of 90°F.

In an effort to cool a 12-fluid-oz drink in a can, which is 5 in high and has a diameter of 2.5 in, a person grabs the can and starts shaking it in the iced water of the chest at 32°F. The temperature of the drink can be assumed to be uniform at all times, and the heat transfer coefficient between the iced water and the aluminum can is 30 Btu/h·ft<sup>2</sup>·°F. Using the properties of water for the drink, estimate how long it will take for the canned drink to cool to 40°F.

**4–144** Two metal rods are being heated in an oven with uniform ambient temperature of 1000°C and convection heat transfer coefficient of 25 W/m<sup>2</sup>·K. Rod A is made of aluminum ( $\rho = 2702 \text{ kg/m}^3$ ,  $c_p = 903 \text{ J/kg}\cdot\text{K}$ , and  $k = 237 \text{ W/m}\cdot\text{K}$ ) and rod B is made of stainless steel ( $\rho = 8238 \text{ kg/m}^3$ ,  $c_p = 468 \text{ J/kg}\cdot\text{K}$ , and  $k = 13.4 \text{ W/m}\cdot\text{K}$ ). Both rods have diameter of 25 mm and length of 1 m. If the initial temperature of both rods is 15°C, determine the average temperatures of both rods after 5 minutes elapsed time.

**4–145** Stainless steel ball bearings ( $\rho = 8085 \text{ kg/m}^3$ ,  $k = 15.1 \text{ W/m}\cdot\text{C}$ ,  $c_p = 0.480 \text{ kJ/kg}\cdot\text{C}$ , and  $\alpha = 3.91 \times 10^{-6} \text{ m}^2/\text{s}$ ) having a diameter of 1.2 cm are to be quenched in water. The balls leave the oven at a uniform temperature of 900°C and are exposed to air at 30°C for a while before they are dropped into the water. If the temperature of the balls is not to fall below 850°C prior to quenching and the heat transfer coefficient in the air is 125 W/m<sup>2</sup>·C, determine how long they can stand in the air before being dropped into the water.

**4–146** During a fire, the trunks of some dry oak trees ( $k = 0.17 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.28 \times 10^{-7} \text{ m}^2/\text{s}$ ) that are initially at a uniform temperature of 30°C are exposed to hot gases at 520°C for a period of 5 h, with a heat transfer coefficient of 65 W/m<sup>2</sup>·K on the surface. The ignition temperature of the trees is 410°C. Treating the trunks of the trees as long cylindrical rods of diameter 20 cm, determine if these dry trees will ignite as the fire sweeps through them. Solve this problem using analytical one-term approximation method (not the Heisler charts).

FIGURE P4–146

**4–147** The thermal conductivity of a solid whose density and specific heat are known can be determined from the relation  $k = \alpha/\rho c_p$  after evaluating the thermal diffusivity  $\alpha$ .

Consider a 2-cm-diameter cylindrical rod made of a sample material whose density and specific heat are 3700 kg/m<sup>3</sup> and 920 J/kg·K, respectively. The sample is initially at a uniform temperature of 25°C. In order to measure the temperatures of the sample at its surface and its center, a thermocouple is inserted to the center of the sample along the centerline, and another thermocouple is welded into a small hole drilled on the surface. The sample is dropped into boiling water at 100°C. After 3 min, the surface and the center temperatures are recorded to be 93°C and 75°C, respectively. Determine the thermal diffusivity and the thermal conductivity of the material.

FIGURE P4–147

**4–148E** In *Betty Crocker's Cookbook*, it is stated that it takes 5 h to roast a 14-lb stuffed turkey initially at 40°F in an oven maintained at 325°F. It is recommended that a meat thermometer be used to monitor the cooking, and the turkey is considered done when the thermometer inserted deep into the thickest part of the breast or thigh without touching the bone registers 185°F. The turkey can be treated as a homogeneous spherical object with the properties  $\rho = 75 \text{ lbm/ft}^3$ ,  $c_p = 0.98 \text{ Btu/lbm}\cdot\text{°F}$ ,  $k = 0.26 \text{ Btu/h}\cdot\text{ft}\cdot\text{°F}$ , and  $\alpha = 0.0035 \text{ ft}^2/\text{h}$ . Assuming the tip of the thermometer is at one-third radial distance from the center of the turkey, determine (a) the average heat transfer coefficient at the surface of the turkey, (b) the temperature of the skin of the turkey when it is done, and (c) the total amount of heat transferred to the turkey in the oven. Will the reading of the thermometer be more or less than 185°F 5 min after the turkey is taken out of the oven?

**4–149** A watermelon initially at 35°C is to be cooled by dropping it into a lake at 15°C. After 4 h and 40 min of cooling, the center temperature of watermelon is measured to be 20°C. Treating the watermelon as a 20-cm-diameter sphere and using the properties  $k = 0.618 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\rho = 995 \text{ kg/m}^3$ , and  $c_p = 4.18 \text{ kJ/kg}\cdot\text{K}$ , determine the average heat transfer coefficient and the surface temperature of watermelon at the end of the cooling period. Solve this problem using analytical one-term approximation method (not the Heisler charts).

**4–150** Spherical glass beads coming out of a kiln are allowed to cool in a room temperature of 30°C. A glass bead with a diameter of 10 mm and an initial temperature of 400°C is allowed to cool for 3 minutes. If the convection heat transfer coefficient is 28 W/m<sup>2</sup>·K, determine the temperature at the center of the glass bead using (a) Table 4–2 and (b) the Heisler chart (Figure 4–19). The glass bead has properties of  $\rho = 2800 \text{ kg/m}^3$ ,  $c_p = 750 \text{ J/kg}\cdot\text{K}$ , and  $k = 0.7 \text{ W/m}\cdot\text{K}$ .

**4–151** The water main in the cities must be placed at sufficient depth below the earth's surface to avoid freezing during extended periods of subfreezing temperatures. Determine the minimum depth at which the water main must be placed at a location where the soil is initially at  $15^{\circ}\text{C}$  and the earth's surface temperature under the worst conditions is expected to remain at  $-10^{\circ}\text{C}$  for a period of 75 days. Take the properties of soil at that location to be  $k = 0.7 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.4 \times 10^{-5} \text{ m}^2/\text{s}$ . *Answer: 7.05 m*

**4–152** A 40-cm-thick brick wall ( $k = 0.72 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.6 \times 10^{-6} \text{ m}^2/\text{s}$ ) is heated to an average temperature of  $18^{\circ}\text{C}$  by the heating system and the solar radiation incident on it during the day. During the night, the outer surface of the wall is exposed to cold air at  $-3^{\circ}\text{C}$  with an average heat transfer coefficient of  $20 \text{ W/m}^2\cdot\text{K}$ , determine the wall temperatures at distances 15, 30, and 40 cm from the outer surface for a period of 2 h.

**4–153** In an event of a volcano eruption, lava at  $1200^{\circ}\text{C}$  is found flowing on the ground. The ground was initially at  $15^{\circ}\text{C}$  and the lava flow has a convection heat transfer coefficient of  $3500 \text{ W/m}^2\cdot\text{K}$ . Determine the ground surface (a) temperature and (b) heat flux after 2 s of lava flow. Assume the ground has properties of dry soil.

**4–154** A large heated steel block ( $\rho = 7832 \text{ kg/m}^3$ ,  $c_p = 434 \text{ J/kg}\cdot\text{K}$ ,  $k = 63.9 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 18.8 \times 10^{-6} \text{ m}^2/\text{s}$ ) is allowed to cool in a room at  $25^{\circ}\text{C}$ . The steel block has an initial temperature of  $450^{\circ}\text{C}$  and the convection heat transfer coefficient is  $25 \text{ W/m}^2\cdot\text{K}$ . Assuming that the steel block can be treated as a quarter-infinite medium, determine the temperature at the edge of the steel block after 10 minutes of cooling.

**4–155** A large iron slab ( $\rho = 7870 \text{ kg/m}^3$ ,  $c_p = 447 \text{ J/kg}\cdot\text{K}$ , and  $k = 80.2 \text{ W/m}\cdot\text{K}$ ) was initially heated to a uniform temperature of  $150^{\circ}\text{C}$  and then placed on concrete floor ( $\rho = 1600 \text{ kg/m}^3$ ,  $c_p = 840 \text{ J/kg}\cdot\text{K}$ , and  $k = 0.79 \text{ W/m}\cdot\text{K}$ ). The concrete floor was initially at a uniform temperature of  $30^{\circ}\text{C}$ . Determine (a) The surface temperature between the iron slab and concrete floor and (b) The temperature of the concrete floor at the depth of 25 mm, if the surface temperature remains constant after 15 minutes.

FIGURE P4–155

**4–156** A hot dog can be considered to be a 12-cm-long cylinder whose diameter is 2 cm and whose properties are

$\rho = 980 \text{ kg/m}^3$ ,  $c_p = 3.9 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.76 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 2 \times 10^{-7} \text{ m}^2/\text{s}$ . A hot dog initially at  $5^{\circ}\text{C}$  is dropped into boiling water at  $100^{\circ}\text{C}$ . The heat transfer coefficient at the surface of the hot dog is estimated to be  $600 \text{ W/m}^2\cdot\text{K}$ . If the hot dog is considered cooked when its center temperature reaches  $80^{\circ}\text{C}$ , determine how long it will take to cook it in the boiling water.

FIGURE P4–156

**4–157** Consider the engine block of a car made of cast iron ( $k = 52 \text{ W/m}\cdot\text{K}$  and  $\alpha = 1.7 \times 10^{-5} \text{ m}^2/\text{s}$ ). The engine can be considered to be a rectangular block whose sides are 80 cm, 40 cm, and 40 cm. The engine is at a temperature of  $150^{\circ}\text{C}$  when it is turned off. The engine is then exposed to atmospheric air at  $17^{\circ}\text{C}$  with a heat transfer coefficient of  $6 \text{ W/m}^2\cdot\text{K}$ . Determine (a) the center temperature of the top surface whose sides are 80 cm and 40 cm and (b) the corner temperature after 45 min of cooling.

**4–158** A man is found dead in a room at  $16^{\circ}\text{C}$ . The surface temperature on his waist is measured to be  $23^{\circ}\text{C}$  and the heat transfer coefficient is estimated to be  $9 \text{ W/m}^2\cdot\text{K}$ . Modeling the body as 28-cm diameter, 1.80-m-long cylinder, estimate how long it has been since he died. Take the properties of the body to be  $k = 0.62 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$ , and assume the initial temperature of the body to be  $36^{\circ}\text{C}$ .

#### Fundamentals of Engineering (FE) Exam Problems

**4–159** The Biot number can be thought of as the ratio of

- The conduction thermal resistance to the convective thermal resistance.
- The convective thermal resistance to the conduction thermal resistance.
- The thermal energy storage capacity to the conduction thermal resistance.
- The thermal energy storage capacity to the convection thermal resistance.
- None of the above.

**4–160** Lumped system analysis of transient heat conduction situations is valid when the Biot number is

- very small
- approximately one
- very large
- any real number
- cannot say unless the Fourier number is also known.

**4–161** Polyvinylchloride automotive body panels ( $k = 0.092 \text{ W/m}\cdot\text{K}$ ,  $c_p = 1.05 \text{ kJ/kg}\cdot\text{K}$ ,  $\rho = 1714 \text{ kg/m}^3$ ), 3-mm thick, emerge from an injection molder at  $120^{\circ}\text{C}$ . They need to be cooled to  $40^{\circ}\text{C}$  by exposing both sides of the panels to  $20^{\circ}\text{C}$  air before they can be handled. If the convective heat transfer

coefficient is  $30 \text{ W/m}^2\text{-K}$  and radiation is not considered, the time that the panels must be exposed to air before they can be handled is

- (a) 1.6 min    (b) 2.4 min    (c) 2.8 min
- (d) 3.5 min    (e) 4.2 min

**4-162** A steel casting cools to 90 percent of the original temperature difference in 30 min in still air. The time it takes to cool this same casting to 90 percent of the original temperature difference in a moving air stream whose convective heat transfer coefficient is 5 times that of still air is

- (a) 3 min    (b) 6 min    (c) 9 min
- (d) 12 min    (e) 15 min

**4-163** An 18-cm-long, 16-cm-wide, and 12-cm-high hot iron block ( $\rho = 7870 \text{ kg/m}^3$ ,  $c_p = 447 \text{ J/kg}\cdot\text{K}$ ) initially at  $20^\circ\text{C}$  is placed in an oven for heat treatment. The heat transfer coefficient on the surface of the block is  $100 \text{ W/m}^2\text{-K}$ . If it is required that the temperature of the block rises to  $750^\circ\text{C}$  in a 25-min period, the oven must be maintained at

- (a)  $750^\circ\text{C}$     (b)  $830^\circ\text{C}$     (c)  $875^\circ\text{C}$
- (d)  $910^\circ\text{C}$     (e)  $1000^\circ\text{C}$

**4-164** A 10-cm-inner diameter, 30-cm-long can filled with water initially at  $25^\circ\text{C}$  is put into a household refrigerator at  $3^\circ\text{C}$ . The heat transfer coefficient on the surface of the can is  $14 \text{ W/m}^2\text{-K}$ . Assuming that the temperature of the water remains uniform during the cooling process, the time it takes for the water temperature to drop to  $5^\circ\text{C}$  is

- (a) 0.55 h    (b) 1.17 h    (c) 2.09 h
- (d) 3.60 h    (e) 4.97 h

**4-165** A 6-cm-diameter 13-cm-high canned drink ( $\rho = 977 \text{ kg/m}^3$ ,  $k = 0.607 \text{ W/m}\cdot\text{K}$ ,  $c_p = 4180 \text{ J/kg}\cdot\text{K}$ ) initially at  $25^\circ\text{C}$  is to be cooled to  $5^\circ\text{C}$  by dropping it into iced water at  $0^\circ\text{C}$ . Total surface area and volume of the drink are  $A_s = 301.6 \text{ cm}^2$  and  $V = 367.6 \text{ cm}^3$ . If the heat transfer coefficient is  $120 \text{ W/m}^2\text{-K}$ , determine how long it will take for the drink to cool to  $5^\circ\text{C}$ . Assume the can is agitated in water and thus the temperature of the drink changes uniformly with time.

- (a) 1.5 min    (b) 8.7 min    (c) 11.1 min
- (d) 26.6 min    (e) 6.7 min

**4-166** Copper balls ( $\rho = 8933 \text{ kg/m}^3$ ,  $k = 401 \text{ W/m}\cdot\text{K}$ ,  $c_p = 385 \text{ J/kg}\cdot\text{C}$ ,  $\alpha = 1.166 \times 10^{-4} \text{ m}^2/\text{s}$ ) initially at  $200^\circ\text{C}$  are allowed to cool in air at  $30^\circ\text{C}$  for a period of 2 minutes. If the balls have a diameter of 2 cm and the heat transfer coefficient is  $80 \text{ W/m}^2\text{-K}$ , the center temperature of the balls at the end of cooling is

- (a)  $104^\circ\text{C}$     (b)  $87^\circ\text{C}$     (c)  $198^\circ\text{C}$
- (d)  $126^\circ\text{C}$     (e)  $152^\circ\text{C}$

**4-167** Carbon steel balls ( $\rho = 7830 \text{ kg/m}^3$ ,  $k = 64 \text{ W/m}\cdot\text{K}$ ,  $c_p = 434 \text{ J/kg}\cdot\text{K}$ ) initially at  $150^\circ\text{C}$  are quenched in an oil bath at  $20^\circ\text{C}$  for a period of 3 minutes. If the balls have a diameter of 5 cm and the convection heat transfer coefficient is  $450 \text{ W/m}^2\text{-K}$ . The center temperature of the balls after quenching will be (Hint: Check the Biot number).

- (a)  $27.4^\circ\text{C}$     (b)  $143^\circ\text{C}$     (c)  $12.7^\circ\text{C}$
- (d)  $48.2^\circ\text{C}$     (e)  $76.9^\circ\text{C}$

**4-168** In a production facility, large plates made of stainless steel ( $k = 15 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 3.91 \times 10^{-6} \text{ m}^2/\text{s}$ ) of 40 cm thickness are taken out of an oven at a uniform temperature of  $750^\circ\text{C}$ . The plates are placed in a water bath that is kept at a constant temperature of  $20^\circ\text{C}$  with a heat transfer coefficient of  $600 \text{ W/m}^2\text{-K}$ . The time it takes for the surface temperature of the plates to drop to  $100^\circ\text{C}$  is

- (a) 0.28 h    (b) 0.99 h    (c) 2.05 h
- (d) 3.55 h    (e) 5.33 h

**4-169** A long 18-cm-diameter bar made of hardwood ( $k = 0.159 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 1.75 \times 10^{-7} \text{ m}^2/\text{s}$ ) is exposed to air at  $30^\circ\text{C}$  with a heat transfer coefficient of  $8.83 \text{ W/m}^2\text{-K}$ . If the center temperature of the bar is measured to be  $15^\circ\text{C}$  after a period of 3-hours, the initial temperature of the bar is

- (a)  $11.9^\circ\text{C}$     (b)  $4.9^\circ\text{C}$     (c)  $1.7^\circ\text{C}$
- (d)  $0^\circ\text{C}$     (e)  $-9.2^\circ\text{C}$

**4-170** Consider a 7.6-cm-long and 3-cm-diameter cylindrical lamb meat chunk ( $\rho = 1030 \text{ kg/m}^3$ ,  $c_p = 3.49 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.456 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 1.3 \times 10^{-7} \text{ m}^2/\text{s}$ ). Fifteen such meat chunks initially at  $2^\circ\text{C}$  are dropped into boiling water at  $95^\circ\text{C}$  with a heat transfer coefficient of  $1200 \text{ W/m}^2\text{-K}$ . The amount of heat transfer during the first 8 minutes of cooking is

- (a) 71 kJ    (b) 227 kJ    (c) 238 kJ
- (d) 269 kJ    (e) 307 kJ

**4-171** Consider a 7.6-cm-diameter cylindrical lamb meat chunk ( $\rho = 1030 \text{ kg/m}^3$ ,  $c_p = 3.49 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.456 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 1.3 \times 10^{-7} \text{ m}^2/\text{s}$ ). Such a meat chunk initially at  $2^\circ\text{C}$  is dropped into boiling water at  $95^\circ\text{C}$  with a heat transfer coefficient of  $1200 \text{ W/m}^2\text{-K}$ . The time it takes for the center temperature of the meat chunk to rise to  $75^\circ\text{C}$  is

- (a) 136 min    (b) 21.2 min    (c) 13.6 min
- (d) 11.0 min    (e) 8.5 min

**4-172** A potato that may be approximated as a 5.7-cm solid sphere with the properties  $\rho = 910 \text{ kg/m}^3$ ,  $c_p = 4.25 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.68 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.76 \times 10^{-7} \text{ m}^2/\text{s}$ . Twelve such potatoes initially at  $25^\circ\text{C}$  are to be cooked by placing them in an oven maintained at  $250^\circ\text{C}$  with a heat transfer coefficient of  $95 \text{ W/m}^2\text{-K}$ . The amount of heat transfer to the potatoes by the time the center temperature reaches  $100^\circ\text{C}$  is

- (a) 56 kJ    (b) 666 kJ    (c) 838 kJ
- (d) 940 kJ    (e) 1088 kJ

**4-173** A small chicken ( $k = 0.45 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$ ) can be approximated as an 11.25-cm-diameter solid sphere. The chicken is initially at a uniform temperature of  $8^\circ\text{C}$  and is to be cooked in an oven maintained at  $220^\circ\text{C}$  with a heat transfer coefficient of  $80 \text{ W/m}^2\text{-K}$ . With this idealization, the temperature at the center of the chicken after a 90-min period is

- (a)  $25^\circ\text{C}$     (b)  $61^\circ\text{C}$     (c)  $89^\circ\text{C}$
- (d)  $122^\circ\text{C}$     (e)  $168^\circ\text{C}$

**4-174** A potato may be approximated as a 5.7-cm-diameter solid sphere with the properties  $\rho = 910 \text{ kg/m}^3$ ,  $c_p = 4.25 \text{ kJ/kg}\cdot\text{K}$ ,  $k = 0.68 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 1.76 \times 10^{-7} \text{ m}^2/\text{s}$ . Twelve such potatoes initially at  $25^\circ\text{C}$  are to be cooked by placing them in an oven maintained at  $250^\circ\text{C}$  with a heat transfer coefficient of  $95 \text{ W/m}^2\cdot\text{K}$ . The amount of heat transfer to the potatoes during a 30-min period is

- (a) 77 kJ
- (b) 483 kJ
- (c) 927 kJ
- (d) 970 kJ
- (e) 1012 kJ

**4-175** When water, as in a pond or lake, is heated by warm air above it, it remains stable, does not move, and forms a warm layer of water on top of a cold layer. Consider a deep lake ( $k = 0.6 \text{ W/m}\cdot\text{K}$ ,  $c_p = 4.179 \text{ kJ/kg}\cdot\text{K}$ ) that is initially at a uniform temperature of  $2^\circ\text{C}$  and has its surface temperature suddenly increased to  $20^\circ\text{C}$  by a spring weather front. The temperature of the water 1 m below the surface 400 hours after this change is

- (a)  $2.1^\circ\text{C}$
- (b)  $4.2^\circ\text{C}$
- (c)  $6.3^\circ\text{C}$
- (d)  $8.4^\circ\text{C}$
- (e)  $10.2^\circ\text{C}$

**4-176** A large chunk of tissue at  $35^\circ\text{C}$  with a thermal diffusivity of  $1 \times 10^{-7} \text{ m}^2/\text{s}$  is dropped into iced water. The water is well-stirred so that the surface temperature of the tissue drops to  $0^\circ\text{C}$  at time zero and remains at  $0^\circ\text{C}$  at all times. The temperature of the tissue after 4 minutes at a depth of 1 cm is

- (a)  $5^\circ\text{C}$
- (b)  $30^\circ\text{C}$
- (c)  $25^\circ\text{C}$
- (d)  $20^\circ\text{C}$
- (e)  $10^\circ\text{C}$

**4-177** The 40-cm-thick roof of a large room made of concrete ( $k = 0.79 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 5.88 \times 10^{-7} \text{ m}^2/\text{s}$ ) is initially at a uniform temperature of  $15^\circ\text{C}$ . After a heavy snow storm, the outer surface of the roof remains covered with snow at  $-5^\circ\text{C}$ . The roof temperature at 18.2 cm distance from the outer surface after a period of 2 hours is

- (a)  $14^\circ\text{C}$
- (b)  $12.5^\circ\text{C}$
- (c)  $7.8^\circ\text{C}$
- (d)  $0^\circ\text{C}$
- (e)  $-5^\circ\text{C}$

### Design and Essay Problems

**4-178** Conduct the following experiment at home to determine the combined convection and radiation heat transfer

coefficient at the surface of an apple exposed to the room air. You will need two thermometers and a clock.

First, weigh the apple and measure its diameter. You can measure its volume by placing it in a large measuring cup halfway filled with water, and measuring the change in volume when it is completely immersed in the water. Refrigerate the apple overnight so that it is at a uniform temperature in the morning and measure the air temperature in the kitchen. Then take the apple out and stick one of the thermometers to its middle and the other just under the skin. Record both temperatures every 5 min for an hour. Using these two temperatures, calculate the heat transfer coefficient for each interval and take their average. The result is the combined convection and radiation heat transfer coefficient for this heat transfer process. Using your experimental data, also calculate the thermal conductivity and thermal diffusivity of the apple and compare them to the values given above.

**4-179** Repeat Prob. 4-178 using a banana instead of an apple. The thermal properties of bananas are practically the same as those of apples.

**4-180** Conduct the following experiment to determine the time constant for a can of soda and then predict the temperature of the soda at different times. Leave the soda in the refrigerator overnight. Measure the air temperature in the kitchen and the temperature of the soda while it is still in the refrigerator by taping the sensor of the thermometer to the outer surface of the can. Then take the soda out and measure its temperature again in 5 min. Using these values, calculate the exponent  $b$ . Using this  $b$ -value, predict the temperatures of the soda in 10, 15, 20, 30, and 60 min and compare the results with the actual temperature measurements. Do you think the lumped system analysis is valid in this case?

**4-181** Citrus trees are very susceptible to cold weather, and extended exposure to subfreezing temperatures can destroy the crop. In order to protect the trees from occasional cold fronts with subfreezing temperatures, tree growers in Florida usually install water sprinklers on the trees. When the temperature drops below a certain level, the sprinklers spray water on the trees and their fruits to protect them against the damage the subfreezing temperatures can cause. Explain the basic mechanism behind this protection measure and write an essay on how the system works in practice.

# NUMERICAL METHODS IN HEAT CONDUCTION

**S**o far we have mostly considered relatively simple heat conduction problems involving *simple geometries* with simple boundary conditions because only such simple problems can be solved *analytically*. But many problems encountered in practice involve *complicated geometries* with complex boundary conditions or variable properties, and cannot be solved analytically. In such cases, sufficiently accurate approximate solutions can be obtained by computers using a *numerical method*.

*Analytical solution methods* such as those presented in Chapter 2 are based on solving the governing differential equation together with the boundary conditions. They result in solution functions for the temperature at *every point* in the medium. Numerical methods, on the other hand, are based on replacing the differential equation by a set of  $n$  algebraic equations for the unknown temperatures at  $n$  selected points in the medium, and the simultaneous solution of these equations results in the temperature values at those *discrete points*.

There are several ways of obtaining the numerical formulation of a heat conduction problem, such as the *finite difference* method, the *finite element* method, the *boundary element* method, and the *energy balance* (or control volume) method. Each method has its own advantages and disadvantages, and each is used in practice. In this chapter, we use primarily the *energy balance* approach since it is based on the familiar energy balances on control volumes instead of heavy mathematical formulations, and thus it gives a better physical feel for the problem. Besides, it results in the same set of algebraic equations as the finite difference method. In this chapter, the numerical formulation and solution of heat conduction problems are demonstrated for both steady and transient cases in various geometries.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Understand the limitations of analytical solutions of conduction problems, and the need for computation-intensive numerical methods,
- Express derivatives as differences, and obtain finite difference formulations,
- Solve steady one- or two-dimensional conduction problems numerically using the finite difference method, and
- Solve transient one- or two-dimensional conduction problems using the finite difference method.

## 5–1 ▪ WHY NUMERICAL METHODS?

The ready availability of high-speed computers and easy-to-use powerful software packages has had a major impact on engineering education and practice in recent years. Engineers in the past had to rely on *analytical skills* to solve significant engineering problems, and thus they had to undergo a rigorous training in mathematics. Today's engineers, on the other hand, have access to a tremendous amount of *computation power* under their fingertips, and they mostly need to understand the physical nature of the problem and interpret the results. But they also need to understand how calculations are performed by the computers to develop an awareness of the processes involved and the limitations, while avoiding any possible pitfalls.

In Chapter 2, we solved various heat conduction problems in various geometries in a systematic but highly mathematical manner by (1) deriving the governing differential equation by performing an energy balance on a differential volume element, (2) expressing the boundary conditions in the proper mathematical form, and (3) solving the differential equation and applying the boundary conditions to determine the integration constants. This resulted in a solution function for the temperature distribution in the medium, and the solution obtained in this manner is called the analytical solution of the problem. For example, the mathematical formulation of one-dimensional steady heat conduction in a sphere of radius  $r_o$  whose outer surface is maintained at a uniform temperature of  $T_1$  with uniform heat generation at a rate of  $\dot{e}$  was expressed as (Fig. 5–1)

Solution:

$$T(r) = T_1 + \frac{\dot{e}}{6k} (r_o^2 - r^2)$$

$$\dot{Q}(r) = -kA \frac{dT}{dr} = \frac{4\pi r^3 \dot{e}}{3}$$

whose (analytical) solution is

$$T(r) = T_1 + \frac{\dot{e}}{6k} (r_o^2 - r^2) \quad (5-2)$$

This is certainly a very desirable form of solution since the temperature at any point within the sphere can be determined simply by substituting the  $r$ -coordinate of the point into the analytical solution function above. The analytical solution of a problem is also referred to as the exact solution since it satisfies the differential equation and the boundary conditions. This can be verified by substituting the solution function into the differential equation and the boundary conditions. Further, the *rate of heat transfer* at any location within the sphere or its surface can be determined by taking the derivative of the solution function  $T(r)$  and substituting it into Fourier's law as

$$\dot{Q}(r) = -kA \frac{dT}{dr} = -k(4\pi r^2) \left( -\frac{\dot{e}r}{3k} \right) = \frac{4\pi r^3 \dot{e}}{3} \quad (5-3)$$

The analysis above did not require any mathematical sophistication beyond the level of *simple integration*, and you are probably wondering why anyone

would ask for something else. After all, the solutions obtained are exact and easy to use. Besides, they are instructive since they show clearly the functional dependence of temperature and heat transfer on the independent variable  $r$ . Well, there are several reasons for searching for alternative solution methods.

## 1 Limitations

Analytical solution methods are limited to *highly simplified problems* in *simple geometries* (Fig. 5–2). The geometry must be such that its entire surface can be described mathematically in a coordinate system by setting the variables equal to constants. That is, it must fit into a coordinate system *perfectly* with nothing sticking out or in. In the case of one-dimensional heat conduction in a solid sphere of radius  $r_o$ , for example, the entire outer surface can be described by  $r = r_o$ . Likewise, the surfaces of a finite solid cylinder of radius  $r_o$  and height  $H$  can be described by  $r = r_o$  for the side surface and  $z = 0$  and  $z = H$  for the bottom and top surfaces, respectively. Even minor complications in geometry can make an analytical solution impossible. For example, a spherical object with an extrusion like a *handle* at some location is impossible to handle analytically since the boundary conditions in this case cannot be expressed in any familiar coordinate system.

Even in simple geometries, heat transfer problems cannot be solved analytically if the *thermal conditions* are not sufficiently simple. For example, the consideration of the variation of thermal conductivity with temperature, the variation of the heat transfer coefficient over the surface, or the radiation heat transfer on the surfaces can make it impossible to obtain an analytical solution. Therefore, analytical solutions are limited to problems that are simple or can be simplified with reasonable approximations.

## 2 Better Modeling

We mentioned earlier that analytical solutions are exact solutions since they do not involve any approximations. But this statement needs some clarification. Distinction should be made between an *actual real-world problem* and the *mathematical model* that is an idealized representation of it. The solutions we get are the solutions of mathematical models, and the degree of applicability of these solutions to the actual physical problems depends on the accuracy of the model. An “approximate” solution of a realistic model of a physical problem is usually more accurate than the “exact” solution of a crude mathematical model (Fig. 5–3).

When attempting to get an analytical solution to a physical problem, there is always the tendency to *oversimplify* the problem to make the mathematical model sufficiently simple to warrant an analytical solution. Therefore, it is common practice to ignore any effects that cause mathematical complications such as nonlinearities in the differential equation or the boundary conditions. So it comes as no surprise that *nonlinearities* such as temperature dependence of thermal conductivity and the radiation boundary conditions are seldom considered in analytical solutions. A mathematical model intended for a numerical solution is likely to represent the actual problem better. Therefore, the numerical solution of engineering problems has now become the norm rather than the exception even when analytical solutions are available.

**FIGURE 5–2**

Analytical solution methods are limited to simplified problems in simple geometries.

**FIGURE 5–3**

The approximate numerical solution of a real-world problem may be more accurate than the exact (analytical) solution of an oversimplified model of that problem.

Analytical solution:

$$\frac{T(r, z) - T_\infty}{T_0 - T_\infty} = \sum_{n=1}^{\infty} \frac{J_0(\lambda_n r)}{\lambda_n J_1(\lambda_n r_o)} \frac{\sinh \lambda_n (L - z)}{\sinh (\lambda_n L)}$$

where  $\lambda_n$ 's are roots of  $J_0(\lambda_n r_o) = 0$

**FIGURE 5–4**

Some analytical solutions are very complex and difficult to use.

### 3 Flexibility

Engineering problems often require extensive *parametric studies* to understand the influence of some variables on the solution in order to choose the right set of variables and to answer some “what-if” questions. This is an *iterative process* that is extremely tedious and time-consuming if done by hand. Computers and numerical methods are ideally suited for such calculations, and a wide range of related problems can be solved by minor modifications in the code or input variables. Today it is almost unthinkable to perform any significant optimization studies in engineering without the power and flexibility of computers and numerical methods.

### 4 Complications

Some problems can be solved analytically, but the solution procedure is so complex and the resulting solution expressions so complicated that it is not worth all that effort. With the exception of steady one-dimensional or transient lumped system problems, all heat conduction problems result in *partial* differential equations. Solving such equations usually requires mathematical sophistication beyond that acquired at the undergraduate level, such as orthogonality, eigenvalues, Fourier and Laplace transforms, Bessel and Legendre functions, and infinite series. In such cases, the evaluation of the solution, which often involves double or triple summations of infinite series at a specified point, is a challenge in itself (Fig. 5–4). Therefore, even when the solutions are available in some handbooks, they are intimidating enough to scare prospective users away.

### 5 Human Nature

As human beings, we like to sit back and make wishes, and we like our wishes to come true without much effort. The invention of TV remote controls made us feel like kings in our homes since the commands we give in our comfortable chairs by pressing buttons are immediately carried out by the obedient TV sets. After all, what good is cable TV without a remote control. We certainly would love to continue being the king in our little cubicle in the engineering office by solving problems at the press of a button on a computer (until they invent a remote control for the computers, of course). Well, this might have been a fantasy yesterday, but it is a reality today. Practically all engineering offices today are equipped with *high-powered computers* with *sophisticated software packages*, with impressive presentation-style colorful output in graphical and tabular form (Fig. 5–5). Besides, the results are as accurate as the analytical results for all practical purposes. The computers have certainly changed the way engineering is practiced.

The discussions above should not lead you to believe that analytical solutions are unnecessary and that they should be discarded from the engineering curriculum. On the contrary, insight to the *physical phenomena* and *engineering wisdom* is gained primarily through analysis. The “feel” that engineers develop during the analysis of simple but fundamental problems serves as an invaluable tool when interpreting a huge pile of results obtained from a computer when solving a complex problem. A simple analysis by hand for a limiting case can be used to check if the results are in the proper range.

**FIGURE 5–5**

The ready availability of high-powered computers with sophisticated software packages has made numerical solution the norm rather than the exception.

Also, nothing can take the place of getting “ball park” results on a piece of paper during preliminary discussions. The calculators made the basic arithmetic operations by hand a thing of the past, but they did not eliminate the need for instructing grade school children how to add or multiply.

In this chapter, you will learn how to *formulate* and *solve* heat transfer problems numerically using one or more approaches. In your professional life, you will probably solve the heat transfer problems you come across using a professional software package, and you are highly unlikely to write your own programs to solve such problems. (Besides, people will be highly skeptical of the results obtained using your own program instead of using a well-established commercial software package that has stood the test of time.) The insight you gain in this chapter by formulating and solving some heat transfer problems will help you better understand the available software packages and be an informed and responsible user.

## 5–2 • FINITE DIFFERENCE FORMULATION OF DIFFERENTIAL EQUATIONS

The numerical methods for solving differential equations are based on replacing the *differential equations* by *algebraic equations*. In the case of the popular **finite difference** method, this is done by replacing the *derivatives* by *differences*. Below we demonstrate this with both first- and second-order derivatives. But first we give a motivational example.

Consider a man who deposits his money in the amount of  $A_0 = \$100$  in a savings account at an annual interest rate of 18 percent, and let us try to determine the amount of money he will have after one year if interest is compounded continuously (or instantaneously). In the case of simple interest, the money will earn \$18 interest, and the man will have  $100 + 100 \times 0.18 = \$118.00$  in his account after one year. But in the case of compounding, the interest earned during a compounding period will also earn interest for the remaining part of the year, and the year-end balance will be greater than \$118. For example, if the money is compounded twice a year, the balance will be  $100 + 100 \times (0.18/2) = \$109$  after six months, and  $109 + 109 \times (0.18/2) = \$118.81$  at the end of the year. We could also determine the balance  $A$  directly from

$$A = A_0(1 + i)^n = (\$100)(1 + 0.09)^2 = \$118.81 \quad (5-4)$$

where  $i$  is the interest rate for the compounding period and  $n$  is the number of periods. Using the same formula, the year-end balance is determined for monthly, daily, hourly, minutely, and even secondly compounding, and the results are given in Table 5–1.

Note that in the case of daily compounding, the year-end balance will be \$119.72, which is \$1.72 more than the simple interest case. (So it is no wonder that the credit card companies usually charge interest compounded daily when determining the balance.) Also note that compounding at smaller time intervals, even at the end of each second, does not change the result, and we suspect that instantaneous compounding using “differential” time intervals  $dt$  will give the same result. This suspicion is confirmed by obtaining the differential

**TABLE 5–1**

Year-end balance of a \$100 account earning interest at an annual rate of 18 percent for various compounding periods

| Compounding Period | Number of Periods, $n$ | Year-End Balance |
|--------------------|------------------------|------------------|
| 1 year             | 1                      | \$118.00         |
| 6 months           | 2                      | 118.81           |
| 1 month            | 12                     | 119.56           |
| 1 week             | 52                     | 119.68           |
| 1 day              | 365                    | 119.72           |
| 1 hour             | 8760                   | 119.72           |
| 1 minute           | 525,600                | 119.72           |
| 1 second           | 31,536,000             | 119.72           |
| Instantaneous      | $\infty$               | 119.72           |

FIGURE 5-6

The derivative of a function at a point represents the slope of the function at that point.

equation  $dA/dt = iA$  for the balance  $A$ , whose solution is  $A = A_0 \exp(it)$ . Substitution yields

$$A = (\$100)\exp(0.18 \times 1) = \$119.72$$

which is identical to the result for daily compounding. Therefore, replacing a differential time interval  $dt$  by a finite time interval of  $\Delta t = 1$  day gave the same result when rounded to the second decimal place for cents, which leads us into believing that *reasonably accurate results can be obtained by replacing differential quantities by sufficiently small differences*.

Next, we develop the finite difference formulation of heat conduction problems by replacing the derivatives in the differential equations by differences. In the following section we do it using the energy balance method, which does not require any knowledge of differential equations.

Derivatives are the building blocks of differential equations, and thus we first give a brief review of derivatives. Consider a function  $f$  that depends on  $x$ , as shown in Figure 5-6. The **first derivative** of  $f(x)$  at a point is equivalent to the *slope* of a line tangent to the curve at that point and is defined as

$$\frac{df(x)}{dx} = \lim_{\Delta x \rightarrow 0} \frac{\Delta f}{\Delta x} = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{\Delta x} \quad (5-5)$$

which is the ratio of the increment  $\Delta f$  of the function to the increment  $\Delta x$  of the independent variable as  $\Delta x \rightarrow 0$ . If we don't take the indicated limit, we will have the following *approximate* relation for the derivative:

$$\frac{df(x)}{dx} \approx \frac{f(x + \Delta x) - f(x)}{\Delta x} \quad (5-6)$$

This approximate expression of the derivative in terms of differences is the **finite difference form** of the first derivative. The equation above can also be obtained by writing the *Taylor series expansion* of the function  $f$  about the point  $x$ ,

$$f(x + \Delta x) = f(x) + \Delta x \frac{df(x)}{dx} + \frac{1}{2} \Delta x^2 \frac{d^2 f(x)}{dx^2} + \dots \quad (5-7)$$

and neglecting all the terms in the expansion except the first two. The first term neglected is proportional to  $\Delta x^2$ , and thus the *error* involved in each step of this approximation is also proportional to  $\Delta x^2$ . However, the *commutative error* involved after  $M$  steps in the direction of length  $L$  is proportional to  $\Delta x$  since  $M\Delta x^2 = (L/\Delta x)\Delta x^2 = L\Delta x$ . Therefore, the smaller the  $\Delta x$ , the smaller the error, and thus the more accurate the approximation.

Now consider steady one-dimensional heat conduction in a plane wall of thickness  $L$  with heat generation. The wall is subdivided into  $M$  sections of equal thickness  $\Delta x = L/M$  in the  $x$ -direction, separated by planes passing through  $M + 1$  points  $0, 1, 2, \dots, m - 1, m, m + 1, \dots, M$  called **nodes** or **nodal points**, as shown in Figure 5-7. The  $x$ -coordinate of any point  $m$  is simply  $x_m = m\Delta x$ , and the temperature at that point is simply  $T(x_m) = T_m$ .

The heat conduction equation involves the second derivatives of temperature with respect to the space variables, such as  $d^2T/dx^2$ , and the finite difference formulation is based on replacing the second derivatives by appropriate

FIGURE 5-7

Schematic of the nodes and the nodal temperatures used in the development of the finite difference formulation of heat transfer in a plane wall.

differences. But we need to start the process with first derivatives. Using Eq. 5–6, the first derivative of temperature  $dT/dx$  at the midpoints  $m - \frac{1}{2}$  and  $m + \frac{1}{2}$  of the sections surrounding the node  $m$  can be expressed as

$$\left. \frac{dT}{dx} \right|_{m-\frac{1}{2}} \cong \frac{T_m - T_{m-1}}{\Delta x} \quad \text{and} \quad \left. \frac{dT}{dx} \right|_{m+\frac{1}{2}} \cong \frac{T_{m+1} - T_m}{\Delta x} \quad (5-8)$$

Noting that the second derivative is simply the derivative of the first derivative, the second derivative of temperature at node  $m$  can be expressed as

$$\left. \frac{d^2T}{dx^2} \right|_m \cong \frac{\left. \frac{dT}{dx} \right|_{m+\frac{1}{2}} - \left. \frac{dT}{dx} \right|_{m-\frac{1}{2}}}{\Delta x} = \frac{\frac{T_{m+1} - T_m}{\Delta x} - \frac{T_m - T_{m-1}}{\Delta x}}{\Delta x} = \frac{T_{m-1} - 2T_m + T_{m+1}}{\Delta x^2} \quad (5-9)$$

which is the *finite difference representation* of the *second derivative* at a general internal node  $m$ . Note that the second derivative of temperature at a node  $m$  is expressed in terms of the temperatures at node  $m$  and its two neighboring nodes. Then the differential equation

$$\frac{d^2T}{dx^2} + \frac{\dot{e}}{k} = 0 \quad (5-10)$$

which is the governing equation for *steady one-dimensional* heat transfer in a plane wall with heat generation and constant thermal conductivity, can be expressed in the *finite difference* form as (Fig. 5–8)

$$\frac{T_{m-1} - 2T_m + T_{m+1}}{\Delta x^2} + \frac{\dot{e}_m}{k} = 0, \quad m = 1, 2, 3, \dots, M-1 \quad (5-11)$$

where  $\dot{e}_m$  is the rate of heat generation per unit volume at node  $m$ . For the case of no heat generation ( $\dot{e}_m = 0$ ), Eq. 5–11 reduces to  $T_m = \frac{1}{2}(T_{m-1} + T_{m+1})$  which is the most simplified form of the one-dimensional finite difference formulation. The equation simply implies that the temperature of each interior node is the arithmetic average of the temperatures of the two neighboring nodes. If the surface temperatures  $T_0$  and  $T_M$  are specified, the application of this equation to each of the  $M - 1$  interior nodes results in  $M - 1$  equations for the determination of  $M - 1$  unknown temperatures at the interior nodes. Solving these equations simultaneously gives the temperature values at the nodes. If the temperatures at the outer surfaces are not known, then we need to obtain two more equations in a similar manner using the specified boundary conditions. Then the unknown temperatures at  $M + 1$  nodes are determined by solving the resulting system of  $M + 1$  equations in  $M + 1$  unknowns simultaneously.

Note that the *boundary conditions* have no effect on the finite difference formulation of interior nodes of the medium. This is not surprising since the control volume used in the development of the formulation does not involve any part of the boundary. You may recall that the boundary conditions had no effect on the differential equation of heat conduction in the medium either.

The finite difference formulation above can easily be extended to two- or three-dimensional heat transfer problems by replacing each second derivative by a difference equation in that direction. For example, the *finite difference*

**FIGURE 5–8**

The differential equation is valid at every point of a medium, whereas the finite difference equation is valid at discrete points (the nodes) only.

**FIGURE 5-9**

Finite difference mesh for two-dimensional conduction in rectangular coordinates.

*formulation for steady two-dimensional heat conduction* in a region with heat generation and constant thermal conductivity can be expressed in rectangular coordinates as (Fig. 5-9)

$$\frac{T_{m+1,n} - 2T_{m,n} + T_{m-1,n}}{\Delta x^2} + \frac{T_{m,n+1} - 2T_{m,n} + T_{m,n-1}}{\Delta y^2} + \frac{\dot{e}_{m,n}}{k} = 0 \quad (5-12)$$

for  $m = 1, 2, 3, \dots, M - 1$  and  $n = 1, 2, 3, \dots, N - 1$  at any interior node  $(m, n)$ . Note that a rectangular region that is divided into  $M$  equal subregions in the  $x$ -direction and  $N$  equal subregions in the  $y$ -direction has a total of  $(M + 1)(N + 1)$  nodes, and Eq. 5-12 can be used to obtain the finite difference equations at  $(M - 1)(N - 1)$  of these nodes (i.e., all nodes except those at the boundaries).

The finite difference formulation is given above to demonstrate how difference equations are obtained from differential equations. However, we use the *energy balance approach* in the following sections to obtain the numerical formulation because it is more *intuitive* and can handle *boundary conditions* more easily. Besides, the energy balance approach does not require having the differential equation before the analysis.

### 5-3 • ONE-DIMENSIONAL STEADY HEAT CONDUCTION

In this section we develop the finite difference formulation of heat conduction in a plane wall using the energy balance approach and discuss how to solve the resulting equations. The **energy balance method** is based on *subdividing* the medium into a sufficient number of volume elements and then applying an *energy balance* on each element. This is done by first *selecting* the nodal points (or nodes) at which the temperatures are to be determined and then *forming elements* (or control volumes) over the nodes by drawing lines through the midpoints between the nodes. This way, the interior nodes remain at the middle of the elements, and the properties *at the node* such as the temperature and the rate of heat generation represent the *average* properties of the element. Sometimes it is convenient to think of temperature as varying *linearly* between the nodes, especially when expressing heat conduction between the elements using Fourier's law.

To demonstrate the approach, again consider steady one-dimensional heat transfer in a plane wall of thickness  $L$  with heat generation  $\dot{e}(x)$  and constant conductivity  $k$ . The wall is now subdivided into  $M$  equal regions of thickness  $\Delta x = L/M$  in the  $x$ -direction, and the divisions between the regions are selected as the nodes. Therefore, we have  $M + 1$  nodes labeled  $0, 1, 2, \dots, m - 1, m, m + 1, \dots, M$ , as shown in Figure 5-10. The  $x$ -coordinate of any node  $m$  is simply  $x_m = m\Delta x$ , and the temperature at that point is  $T(x_m) = T_m$ . Elements are formed by drawing vertical lines through the midpoints between the nodes. Note that all interior elements represented by interior nodes are full-size elements (they have a thickness of  $\Delta x$ ), whereas the two elements at the boundaries are half-sized.

To obtain a general difference equation for the interior nodes, consider the element represented by node  $m$  and the two neighboring nodes  $m - 1$  and

**FIGURE 5-10**

The nodal points and volume elements for the finite difference formulation of one-dimensional conduction in a plane wall.

$m + 1$ . Assuming the heat conduction to be *into* the element on all surfaces, an energy balance on the element can be expressed as

$$\left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction} \\ \text{at the left} \\ \text{surface} \end{array} \right) + \left( \begin{array}{c} \text{Rate of heat} \\ \text{conduction} \\ \text{at the right} \\ \text{surface} \end{array} \right) + \left( \begin{array}{c} \text{Rate of heat} \\ \text{generation} \\ \text{inside the} \\ \text{element} \end{array} \right) = \left( \begin{array}{c} \text{Rate of change} \\ \text{of the energy} \\ \text{content of} \\ \text{the element} \end{array} \right)$$

or

$$\dot{Q}_{\text{cond, left}} + \dot{Q}_{\text{cond, right}} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} = 0 \quad (5-13)$$

since the energy content of a medium (or any part of it) does not change under *steady* conditions and thus  $\Delta E_{\text{element}} = 0$ . The rate of *heat generation* within the element can be expressed as

$$\dot{E}_{\text{gen, element}} = \dot{e}_m V_{\text{element}} = \dot{e}_m A \Delta x \quad (5-14)$$

where  $\dot{e}_m$  is the rate of heat generation per unit volume in  $\text{W/m}^3$  evaluated at node  $m$  and treated as a constant for the entire element, and  $A$  is heat transfer area, which is simply the inner (or outer) surface area of the wall.

Recall that when temperature varies *linearly*, the steady rate of heat conduction across a plane wall of thickness  $L$  can be expressed as

$$\dot{Q}_{\text{cond}} = kA \frac{\Delta T}{L} \quad (5-15)$$

where  $\Delta T$  is the temperature change across the wall and the direction of heat transfer is from the high temperature side to the low temperature. In the case of a plane wall with heat generation, the variation of temperature is not linear and thus the relation above is not applicable. However, the variation of temperature between the nodes can be *approximated* as being linear in the determination of heat conduction across a thin layer of thickness  $\Delta x$  between two nodes (Fig. 5-11). Obviously the smaller the distance  $\Delta x$  between two nodes, the more accurate is this approximation. (In fact, such approximations are the reason for classifying the numerical methods as approximate solution methods. In the limiting case of  $\Delta x$  approaching zero, the formulation becomes exact and we obtain a differential equation.) Noting that the direction of heat transfer on both surfaces of the element is assumed to be *toward* the node  $m$ , the rate of heat conduction at the left and right surfaces can be expressed as

$$\dot{Q}_{\text{cond, left}} = kA \frac{T_{m-1} - T_m}{\Delta x} \quad \text{and} \quad \dot{Q}_{\text{cond, right}} = kA \frac{T_{m+1} - T_m}{\Delta x} \quad (5-16)$$

Substituting Eqs. 5-14 and 5-16 into Eq. 5-13 gives

$$kA \frac{T_{m-1} - T_m}{\Delta x} + kA \frac{T_{m+1} - T_m}{\Delta x} + \dot{e}_m A \Delta x = 0 \quad (5-17)$$

which simplifies to

$$\frac{T_{m-1} - 2T_m + T_{m+1}}{\Delta x^2} + \frac{\dot{e}_m}{k} = 0, \quad m = 1, 2, 3, \dots, M - 1 \quad (5-18)$$

FIGURE 5-11

In finite difference formulation, the temperature is assumed to vary linearly between the nodes.

or

$$T_1 - 2T_2 + T_3 + \dot{e}_2 A \Delta x^2 / k = 0$$

(a) Assuming heat transfer to be out of the volume element at the right surface.

or

$$T_1 - 2T_2 + T_3 + \dot{e}_2 A \Delta x^2 / k = 0$$

(b) Assuming heat transfer to be into the volume element at all surfaces.

### FIGURE 5–12

The assumed direction of heat transfer at surfaces of a volume element has no effect on the finite difference formulation.

which is *identical* to the difference equation (Eq. 5–11) obtained earlier. Again, this equation is applicable to each of the  $M - 1$  interior nodes, and its application gives  $M - 1$  equations for the determination of temperatures at  $M + 1$  nodes. The two additional equations needed to solve for the  $M + 1$  unknown nodal temperatures are obtained by applying the energy balance on the two elements at the boundaries (unless, of course, the boundary temperatures are specified).

You are probably thinking that if heat is conducted into the element from both sides, as assumed in the formulation, the temperature of the medium will have to rise and thus heat conduction cannot be steady. Perhaps a more realistic approach would be to assume the heat conduction to be *into* the element on the left side and *out of* the element on the right side. If you repeat the formulation using this assumption, you will again obtain the same result since the heat conduction term on the right side in this case involves  $T_m - T_{m+1}$  instead of  $T_{m+1} - T_m$ , which is subtracted instead of being added. Therefore, the assumed direction of heat conduction at the surfaces of the volume elements has no effect on the formulation, as shown in Figure 5–12. (Besides, the actual direction of heat transfer is usually not known.) However, it is convenient to assume heat conduction to be into the element at all surfaces and not worry about the sign of the conduction terms. Then all temperature differences in conduction relations are expressed as the temperature of the neighboring node minus the temperature of the node under consideration, and all conduction terms are added.

### Boundary Conditions

Above we have developed a general relation for obtaining the finite difference equation for each interior node of a plane wall. This relation is not applicable to the nodes on the boundaries, however, since it requires the presence of nodes on both sides of the node under consideration, and a boundary node does not have a neighboring node on at least one side. Therefore, we need to obtain the finite difference equations of boundary nodes separately. This is best done by applying an *energy balance* on the volume elements of boundary nodes.

Boundary conditions most commonly encountered in practice are the *specified temperature*, *specified heat flux*, *convection*, and *radiation* boundary conditions, and here we develop the finite difference formulations for them for the case of steady one-dimensional heat conduction in a plane wall of thickness  $L$  as an example. The node number at the left surface at  $x = 0$  is 0, and at the right surface at  $x = L$  it is  $M$ . Note that the width of the volume element for either boundary node is  $\Delta x/2$ .

The **specified temperature** boundary condition is the simplest boundary condition to deal with. For one-dimensional heat transfer through a plane wall of thickness  $L$ , the *specified temperature boundary conditions* on both the left and right surfaces can be expressed as (Fig. 5–13)

$$T(0) = T_0 = \text{Specified value}$$

$$T(L) = T_M = \text{Specified value}$$

(5–19)

where  $T_0$  and  $T_M$  are the specified temperatures at surfaces at  $x = 0$  and  $x = L$ , respectively. Therefore, the specified temperature boundary conditions are

incorporated by simply assigning the given surface temperatures to the boundary nodes. We do not need to write an energy balance in this case unless we decide to determine the rate of heat transfer into or out of the medium after the temperatures at the interior nodes are determined.

When other boundary conditions such as the *specified heat flux, convection, radiation, or combined convection and radiation* conditions are specified at a boundary, the finite difference equation for the node at that boundary is obtained by writing an *energy balance* on the volume element at that boundary. The energy balance is again expressed as

$$\sum_{\text{All sides}} \dot{Q} + \dot{E}_{\text{gen, element}} = 0 \quad (5-20)$$

for heat transfer under *steady* conditions. Again we assume all heat transfer to be *into* the volume element from all surfaces for convenience in formulation, except for specified heat flux since its direction is already specified. Specified heat flux is taken to be a *positive* quantity if into the medium and a *negative* quantity if out of the medium. Then the finite difference formulation at the node  $m = 0$  (at the left boundary where  $x = 0$ ) of a plane wall of thickness  $L$  during steady one-dimensional heat conduction can be expressed as (Fig. 5-14)

$$\dot{Q}_{\text{left surface}} + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-21)$$

where  $A\Delta x/2$  is the *volume* of the volume element (note that the boundary element has half thickness),  $\dot{e}_0$  is the rate of heat generation per unit volume (in  $\text{W}/\text{m}^3$ ) at  $x = 0$ , and  $A$  is the heat transfer area, which is constant for a plane wall. Note that we have  $\Delta x$  in the denominator of the second term instead of  $\Delta x/2$ . This is because the ratio in that term involves the temperature difference between nodes 0 and 1, and thus we must use the distance between those two nodes, which is  $\Delta x$ .

The finite difference form of various boundary conditions can be obtained from Eq. 5-21 by replacing  $\dot{Q}_{\text{left surface}}$  by a suitable expression. Next this is done for various boundary conditions at the left boundary.

### 1. Specified Heat Flux Boundary Condition

$$\dot{q}_0 A + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-22)$$

*Special case: Insulated Boundary ( $\dot{q}_0 = 0$ )*

$$kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-23)$$

### 2. Convection Boundary Condition

$$hA(T_\infty - T_0) + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-24)$$

FIGURE 5-13

Finite difference formulation of specified temperature boundary conditions on both surfaces of a plane wall.

FIGURE 5-14

Schematic for the finite difference formulation of the left boundary node of a plane wall.

### 3. Radiation Boundary Condition

$$\varepsilon\sigma A(T_{\text{surr}}^4 - T_0^4) + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-25)$$

### 4. Combined Convection and Radiation Boundary Condition (Fig. 5-15)

$$hA(T_{\infty} - T_0) + \varepsilon\sigma A(T_{\text{surr}}^4 - T_0^4) + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-26)$$

or

$$h_{\text{combined}} A(T_{\infty} - T_0) + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-27)$$

### 5. Combined Convection, Radiation, and Heat Flux Boundary Condition

$$\dot{q}_0 A + hA(T_{\infty} - T_0) + \varepsilon\sigma A(T_{\text{surr}}^4 - T_0^4) + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0 \quad (5-28)$$

### 6. Interface Boundary Condition

Two different solid media  $A$  and  $B$  are assumed to be in perfect contact, and thus at the same temperature at the interface at node  $m$  (Fig. 5-16). Subscripts  $A$  and  $B$  indicate properties of media  $A$  and  $B$ , respectively.

$$k_A A \frac{T_{m-1} - T_m}{\Delta x} + k_B A \frac{T_{m+1} - T_m}{\Delta x} + \dot{e}_{A,m}(A\Delta x/2) + \dot{e}_{B,m}(A\Delta x/2) = 0 \quad (5-29)$$

In these relations,  $\dot{q}_0$  is the specified heat flux in  $\text{W}/\text{m}^2$ ,  $h$  is the convection coefficient,  $h_{\text{combined}}$  is the combined convection and radiation coefficient,  $T_{\infty}$  is the temperature of the surrounding medium,  $T_{\text{surr}}$  is the temperature of the surrounding surfaces,  $\varepsilon$  is the emissivity of the surface, and  $\sigma$  is the Stefan-Boltzmann constant. The relations above can also be used for node  $M$  on the right boundary by replacing the subscript "0" by " $M$ " and the subscript "1" by " $M - 1$ ".

Note that *thermodynamic temperatures* must be used in radiation heat transfer calculations, and all temperatures should be expressed in K or R when a boundary condition involves radiation to avoid mistakes. We usually try to avoid the *radiation boundary condition* even in numerical solutions since it causes the finite difference equations to be *nonlinear*, which are more difficult to solve.

### Treating Insulated Boundary Nodes as Interior Nodes: The Mirror Image Concept

One way of obtaining the finite difference formulation of a node on an insulated boundary is to treat insulation as "zero" heat flux and to write an energy balance, as done in Eq. 5-23. Another and more practical way is to treat the node on an insulated boundary as an interior node. Conceptually this is done

**FIGURE 5-15**

Schematic for the finite difference formulation of combined convection and radiation on the left boundary of a plane wall.

**FIGURE 5-16**

Schematic for the finite difference formulation of the interface boundary condition for two media  $A$  and  $B$  that are in perfect thermal contact.

by replacing the insulation on the boundary by a *mirror* and considering the reflection of the medium as its extension (Fig. 5–17). This way the node next to the boundary node appears on both sides of the boundary node because of symmetry, converting it into an interior node. Then using the general formula (Eq. 5–18) for an interior node, which involves the sum of the temperatures of the adjoining nodes minus twice the node temperature, the finite difference formulation of a node  $m = 0$  on an insulated boundary of a plane wall can be expressed as

$$\frac{T_{m+1} - 2T_m + T_{m-1}}{\Delta x^2} + \frac{\dot{e}_m}{k} = 0 \rightarrow \frac{T_1 - 2T_0 + T_1}{\Delta x^2} + \frac{\dot{e}_0}{k} = 0 \quad (5-30)$$

which is equivalent to Eq. 5–23 obtained by the energy balance approach.

The mirror image approach can also be used for problems that possess thermal symmetry by replacing the plane of symmetry by a mirror. Alternately, we can replace the plane of symmetry by insulation and consider only half of the medium in the solution. The solution in the other half of the medium is simply the mirror image of the solution obtained.

### EXAMPLE 5–1 Steady Heat Conduction in a Large Uranium Plate

Consider a large uranium plate of thickness  $L = 4$  cm and thermal conductivity  $k = 28$  W/m·K in which heat is generated uniformly at a constant rate of  $\dot{e} = 5 \times 10^6$  W/m<sup>3</sup>. One side of the plate is maintained at 0°C by iced water while the other side is subjected to convection to an environment at  $T_\infty = 30$ °C with a heat transfer coefficient of  $h = 45$  W/m<sup>2</sup>·K, as shown in Figure 5–18. Considering a total of three equally spaced nodes in the medium, two at the boundaries and one at the middle, estimate the exposed surface temperature of the plate under steady conditions using the finite difference approach.

**SOLUTION** A uranium plate is subjected to specified temperature on one side and convection on the other. The unknown surface temperature of the plate is to be determined numerically using three equally spaced nodes.

**Assumptions** 1 Heat transfer through the wall is steady since there is no indication of any change with time. 2 Heat transfer is one-dimensional since the plate is large relative to its thickness. 3 Thermal conductivity is constant. 4 Radiation heat transfer is negligible.

**Properties** The thermal conductivity is given to be  $k = 28$  W/m·K.

**Analysis** The number of nodes is specified to be  $M = 3$ , and they are chosen to be at the two surfaces of the plate and the midpoint, as shown in the figure. Then the nodal spacing  $\Delta x$  becomes

$$\Delta x = \frac{L}{M - 1} = \frac{0.04 \text{ m}}{3 - 1} = 0.02 \text{ m}$$

We number the nodes 0, 1, and 2. The temperature at node 0 is given to be  $T_0 = 0$ °C, and the temperatures at nodes 1 and 2 are to be determined. This problem involves only two unknown nodal temperatures, and thus we need to have only two equations to determine them uniquely. These equations are obtained by applying the finite difference method to nodes 1 and 2.

FIGURE 5–17

A node on an insulated boundary can be treated as an interior node by replacing the insulation by a mirror.

FIGURE 5–18

Schematic for Example 5–1.

Node 1 is an interior node, and the finite difference formulation at that node is obtained directly from Eq. 5–18 by setting  $m = 1$ :

$$\frac{T_0 - 2T_1 + T_2}{\Delta x^2} + \frac{\dot{e}_1}{k} = 0 \rightarrow \frac{0 - 2T_1 + T_2}{\Delta x^2} + \frac{\dot{e}_1}{k} = 0 \rightarrow 2T_1 - T_2 = \frac{\dot{e}_1 \Delta x^2}{k}$$
(1)

Node 2 is a boundary node subjected to convection, and the finite difference formulation at that node is obtained by writing an energy balance on the volume element of thickness  $\Delta x/2$  at that boundary by assuming heat transfer to be into the medium at all sides:

$$hA(T_\infty - T_2) + kA \frac{T_1 - T_2}{\Delta x} + \dot{e}_2(A\Delta x/2) = 0$$

Canceling the heat transfer area  $A$  and rearranging give

$$T_1 - \left(1 + \frac{h\Delta x}{k}\right)T_2 = -\frac{h\Delta x}{k}T_\infty - \frac{\dot{e}_2 \Delta x^2}{2k}$$
(2)

Equations (1) and (2) form a system of two equations in two unknowns  $T_1$  and  $T_2$ . Substituting the given quantities and simplifying gives

$$\begin{aligned} 2T_1 - T_2 &= 71.43 && (\text{in } ^\circ\text{C}) \\ T_1 - 1.032T_2 &= -36.68 && (\text{in } ^\circ\text{C}) \end{aligned}$$

This is a system of two algebraic equations in two unknowns and can be solved easily by the elimination method. Solving the first equation for  $T_1$  and substituting into the second equation result in an equation in  $T_2$  whose solution is

$$T_2 = 136.1^\circ\text{C}$$

This is the temperature of the surface exposed to convection, which is the desired result. Substitution of this result into the first equation gives  $T_1 = 103.8^\circ\text{C}$ , which is the temperature at the middle of the plate.

**Discussion** The purpose of this example is to demonstrate the use of the finite difference method with minimal calculations, and the accuracy of the result was not a major concern. But you might still be wondering how accurate the result obtained above is. After all, we used a mesh of only three nodes for the entire plate, which seems to be rather crude. This problem can be solved analytically as described in Chapter 2, and the analytical (exact) solution can be shown to be

$$T(x) = \frac{0.5\dot{e}hL^2/k + \dot{e}L + T_\infty h}{hL + k}x - \frac{\dot{e}x^2}{2k}$$

Substituting the given quantities, the temperature of the exposed surface of the plate at  $x = L = 0.04$  m is determined to be  $136.0^\circ\text{C}$ , which is almost identical to the result obtained here with the approximate finite difference method (Fig. 5–19). Therefore, highly accurate results can be obtained with numerical methods by using a limited number of nodes.

Finite difference solution:

$$T_2 = 136.1^\circ\text{C}$$

Exact solution:

$$T_2 = 136.0^\circ\text{C}$$

**FIGURE 5–19**

Despite being approximate in nature, highly accurate results can be obtained by numerical methods.

**EXAMPLE 5–2 Heat Transfer from Triangular Fins**

Consider an aluminum alloy fin ( $k = 180 \text{ W/m}\cdot\text{K}$ ) of triangular cross section with length  $L = 5 \text{ cm}$ , base thickness  $b = 1 \text{ cm}$ , and very large width  $w$ , as shown in Figure 5–20. The base of the fin is maintained at a temperature of  $T_0 = 200^\circ\text{C}$ . The fin is losing heat to the surrounding medium at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 15 \text{ W/m}^2\cdot\text{K}$ . Using the finite difference method with six equally spaced nodes along the fin in the  $x$ -direction, determine (a) the temperatures at the nodes, (b) the rate of heat transfer from the fin for  $w = 1 \text{ m}$ , and (c) the fin efficiency.

**SOLUTION** A long triangular fin attached to a surface is considered. The nodal temperatures, the rate of heat transfer, and the fin efficiency are to be determined numerically using six equally spaced nodes.

**Assumptions** 1 Heat transfer is steady since there is no indication of any change with time. 2 The temperature along the fin varies in the  $x$  direction only. 3 Thermal conductivity is constant. 4 Radiation heat transfer is negligible.

**Properties** The thermal conductivity is given to be  $k = 180 \text{ W/m}\cdot\text{K}$ .

**Analysis** (a) The number of nodes in the fin is specified to be  $M = 6$ , and their location is as shown in the figure. Then the nodal spacing  $\Delta x$  becomes

$$\Delta x = \frac{L}{M - 1} = \frac{0.05 \text{ m}}{6 - 1} = 0.01 \text{ m}$$

The temperature at node 0 is given to be  $T_0 = 200^\circ\text{C}$ , and the temperatures at the remaining five nodes are to be determined. Therefore, we need to have five equations to determine them uniquely. Nodes 1, 2, 3, and 4 are interior nodes, and the finite difference formulation for a general interior node  $m$  is obtained by applying an energy balance on the volume element of this node. Noting that heat transfer is steady and there is no heat generation in the fin and assuming heat transfer to be into the medium at all sides, the energy balance can be expressed as

$$\sum_{\text{All sides}} \dot{Q} = 0 \rightarrow kA_{\text{left}} \frac{T_{m-1} - T_m}{\Delta x} + kA_{\text{right}} \frac{T_{m+1} - T_m}{\Delta x} + hA_{\text{conv}}(T_\infty - T_m) = 0$$

Note that heat transfer areas are different for each node in this case, and using geometrical relations, they can be expressed as

$$A_{\text{left}} = (\text{Height} \times \text{Width})_{@m - \frac{1}{2}} = 2w[L - (m - 1/2)\Delta x]\tan \theta$$

$$A_{\text{right}} = (\text{Height} \times \text{Width})_{@m + \frac{1}{2}} = 2w[L - (m + 1/2)\Delta x]\tan \theta$$

$$A_{\text{conv}} = 2 \times \text{Length} \times \text{Width} = 2w(\Delta x/\cos \theta)$$

Substituting,

$$2kw[L - (m - \frac{1}{2})\Delta x]\tan \theta \frac{T_{m-1} - T_m}{\Delta x} + 2kw[L - (m + \frac{1}{2})\Delta x]\tan \theta \frac{T_{m+1} - T_m}{\Delta x} + h \frac{2w\Delta x}{\cos \theta}(T_\infty - T_m) = 0$$

**FIGURE 5–20**

Schematic for Example 5–2 and the volume element of a general interior node of the fin.

Dividing each term by  $2kwL \tan \theta / \Delta x$  gives

$$\left[ 1 - (m - \frac{1}{2}) \frac{\Delta x}{L} \right] (T_{m-1} - T_m) + \left[ 1 - (m + \frac{1}{2}) \frac{\Delta x}{L} \right] (T_{m+1} - T_m) + \frac{h(\Delta x)^2}{kL \sin \theta} (T_\infty - T_m) = 0$$

Note that

$$\tan \theta = \frac{b/2}{L} = \frac{0.5 \text{ cm}}{5 \text{ cm}} = 0.1 \rightarrow \theta = \tan^{-1} 0.1 = 5.71^\circ$$

Also,  $\sin 5.71^\circ = 0.0995$ . Then the substitution of known quantities gives

$$(5.5 - m)T_{m-1} - (10.008 - 2m)T_m + (4.5 - m)T_{m+1} = -0.209$$

Now substituting 1, 2, 3, and 4 for  $m$  results in these finite difference equations for the interior nodes:

$$m = 1: -8.008T_1 + 3.5T_2 = -900.209 \quad (1)$$

$$m = 2: 3.5T_1 - 6.008T_2 + 2.5T_3 = -0.209 \quad (2)$$

$$m = 3: 2.5T_2 - 4.008T_3 + 1.5T_4 = -0.209 \quad (3)$$

$$m = 4: 1.5T_3 - 2.008T_4 + 0.5T_5 = -0.209 \quad (4)$$

The finite difference equation for the boundary node 5 is obtained by writing an energy balance on the volume element of length  $\Delta x/2$  at that boundary, again by assuming heat transfer to be into the medium at all sides (Fig. 5–21):

$$kA_{\text{left}} \frac{T_4 - T_5}{\Delta x} + hA_{\text{conv}} (T_\infty - T_5) = 0$$

where

$$A_{\text{left}} = 2w \frac{\Delta x}{2} \tan \theta \quad \text{and} \quad A_{\text{conv}} = 2w \frac{\Delta x/2}{\cos \theta}$$

Canceling  $w$  in all terms and substituting the known quantities gives

$$T_4 - 1.008T_5 = -0.209 \quad (5)$$

Equations (1) through (5) form a linear system of five algebraic equations in five unknowns. Solving them simultaneously using an equation solver gives

$$\begin{aligned} T_1 &= 198.6^\circ\text{C} & T_2 &= 197.1^\circ\text{C} & T_3 &= 195.7^\circ\text{C} \\ T_4 &= 194.3^\circ\text{C} & T_5 &= 192.9^\circ\text{C} \end{aligned}$$

which is the desired solution for the nodal temperatures.

(b) The total rate of heat transfer from the fin is simply the sum of the heat transfer from each volume element to the ambient, and for  $w = 1 \text{ m}$  it is determined from

**FIGURE 5–21**

Schematic of the volume element of node 5 at the tip of a triangular fin.

$$\dot{Q}_{\text{fin}} = \sum_{m=0}^5 \dot{Q}_{\text{element}, m} = \sum_{m=0}^5 hA_{\text{conv}, m}(T_m - T_{\infty})$$

Noting that the heat transfer surface area is  $w\Delta x/\cos \theta$  for the boundary nodes 0 and 5, and twice as large for the interior nodes 1, 2, 3, and 4, we have

$$\begin{aligned}\dot{Q}_{\text{fin}} &= h \frac{w\Delta x}{\cos \theta} [(T_0 - T_{\infty}) + 2(T_1 - T_{\infty}) + 2(T_2 - T_{\infty}) + 2(T_3 - T_{\infty}) \\ &\quad + 2(T_4 - T_{\infty}) + (T_5 - T_{\infty})] \\ &= h \frac{w\Delta x}{\cos \theta} [T_0 + 2(T_1 + T_2 + T_3 + T_4) + T_5 - 10T_{\infty}]^{\circ}\text{C} \\ &= (15 \text{ W/m}^2\cdot\text{K}) \frac{(1 \text{ m})(0.01 \text{ m})}{\cos 5.71^\circ} [200 + 2 \times 785.7 \\ &\quad + 192.9 - 10 \times 25]^{\circ}\text{C} \\ &= \mathbf{258.4 \text{ W}}\end{aligned}$$

(c) If the entire fin were at the base temperature of  $T_0 = 200^\circ\text{C}$ , the total rate of heat transfer from the fin for  $w = 1 \text{ m}$  would be

$$\begin{aligned}\dot{Q}_{\text{max}} &= hA_{\text{fin, total}}(T_0 - T_{\infty}) = h(2wL/\cos \theta)(T_0 - T_{\infty}) \\ &= (15 \text{ W/m}^2\cdot\text{K})[2(1 \text{ m})(0.05 \text{ m})/\cos 5.71^\circ](200 - 25)^{\circ}\text{C} \\ &= 263.8 \text{ W}\end{aligned}$$

Then the fin efficiency is determined from

$$\eta_{\text{fin}} = \frac{\dot{Q}_{\text{fin}}}{\dot{Q}_{\text{max}}} = \frac{258.4 \text{ W}}{263.8 \text{ W}} = \mathbf{0.98}$$

which is less than 1, as expected. We could also determine the fin efficiency in this case from the proper fin efficiency curve in Chapter 3, which is based on the analytical solution. We would read 0.98 for the fin efficiency, which is identical to the value determined above numerically.

The finite difference formulation of steady heat conduction problems usually results in a system of  $N$  algebraic equations in  $N$  unknown nodal temperatures that need to be solved simultaneously. When  $N$  is small (such as 2 or 3), we can use the elementary *elimination method* to eliminate all unknowns except one and then solve for that unknown (see Example 5–1). The other unknowns are then determined by back substitution. When  $N$  is large, which is usually the case, the elimination method is not practical and we need to use a more systematic approach that can be adapted to computers.

There are numerous systematic approaches available in the literature, and they are broadly classified as **direct** and **iterative** methods. The direct methods are based on a fixed number of well-defined steps that result in the solution in a systematic manner. The iterative methods, on the other hand, are based on an initial guess for the solution that is refined by iteration until

**FIGURE 5–22**

Two general categories of solution methods for solving systems of algebraic equations.

a specified convergence criterion is satisfied (Fig. 5–22). The direct methods usually require a large amount of computer memory and computation time, and they are more suitable for systems with a relatively small number of equations. The computer memory requirements for iterative methods are minimal, and thus they are usually preferred for large systems. The convergence of iterative methods to the desired solution, however, may pose a problem.

One of the simplest iterative methods is the *Gauss-Seidel* iteration. The method applied to a system of  $N$  algebraic equations in  $N$  unknown nodal temperatures proceeds as follows: (1) write the finite difference equations explicitly for each node (the nodal temperature on the left-hand side and all other terms on the right-hand side of the equation), (2) make a reasonable initial guess for each unknown nodal temperature, (3) use the explicit equations to calculate new values for each nodal temperature, *always use the most recent values of the temperature for each node on the right-hand side of the explicit finite difference equation*, and (4) repeat the process until convergence within some tolerable error (specified convergence criterion) is achieved. The method is illustrated in Table 5–2 by solving the five finite difference equations given in Example 5–2 for the five nodal temperatures. As shown in Table 5–2 the first row is the initial guess for the nodal temperatures. Substituting into the explicit equations yields the results displayed in the second row, and so on. The nodal temperatures are considered converged by the fifth iteration, since the successive sixth and seventh iterations do not bring any changes to the temperatures. Comparing with the temperatures calculated in Example 5–2(a), the temperatures obtained using the Gauss-Seidel iterative method are within 0.3°C agreement. The small discrepancy between the two methods is due to *round-off error* (retaining a limited number of digits during the calculations).

**TABLE 5–2**

Application of the *Gauss-Seidel* iterative method to the finite difference equations of Example 5–2.

Finite difference equations in explicit form

$$T_1 = 0.4371T_2 + 112.4137$$

$$T_2 = 0.5826T_1 + 0.4161T_3 + 0.0348$$

$$T_3 = 0.6238T_2 + 0.3743T_4 + 0.0521$$

$$T_4 = 0.7470T_3 + 0.2490T_5 + 0.1041$$

$$T_5 = 0.9921T_4 + 0.2073$$

| Iteration     | Nodal Temperature, °C |       |       |       |       |
|---------------|-----------------------|-------|-------|-------|-------|
|               | $T_1$                 | $T_2$ | $T_3$ | $T_4$ | $T_5$ |

## 5-4 ▪ TWO-DIMENSIONAL STEADY HEAT CONDUCTION

In Section 5–3 we considered one-dimensional heat conduction and assumed heat conduction in other directions to be negligible. Many heat transfer problems encountered in practice can be approximated as being one-dimensional, but this is not always the case. Sometimes we need to consider heat transfer in other directions as well when the variation of temperature in other directions is significant. In this section we consider the numerical formulation and solution of two-dimensional steady heat conduction in rectangular coordinates using the finite difference method. The approach presented below can be extended to three-dimensional cases.

Consider a *rectangular region* in which heat conduction is significant in the  $x$ - and  $y$ -directions. Now divide the  $x$ - $y$  plane of the region into a rectangular mesh of nodal points spaced  $\Delta x$  and  $\Delta y$  apart in the  $x$ - and  $y$ -directions, respectively, as shown in Figure 5–23, and consider a unit depth of  $\Delta z = 1$  in the  $z$ -direction. Our goal is to determine the temperatures at the nodes, and it is convenient to number the nodes and describe their position by the numbers instead of actual coordinates. A logical numbering scheme for two-dimensional problems is the *double subscript notation*  $(m, n)$  where  $m = 0, 1, 2, \dots, M$  is the node count in the  $x$ -direction and  $n = 0, 1, 2, \dots, N$  is the node count in the  $y$ -direction. The coordinates of the node  $(m, n)$  are simply  $x = m\Delta x$  and  $y = n\Delta y$ , and the temperature at the node  $(m, n)$  is denoted by  $T_{m,n}$ .

Now consider a *volume element* of size  $\Delta x \times \Delta y \times 1$  centered about a general interior node  $(m, n)$  in a region in which heat is generated at a rate of  $\dot{e}$  and the thermal conductivity  $k$  is constant, as shown in Figure 5–24. Again assuming the direction of heat conduction to be *toward* the node under consideration at all surfaces, the energy balance on the volume element can be expressed as

$$\left( \begin{array}{l} \text{Rate of heat conduction} \\ \text{at the left, top, right,} \\ \text{and bottom surfaces} \end{array} \right) + \left( \begin{array}{l} \text{Rate of heat} \\ \text{generation inside} \\ \text{the element} \end{array} \right) = \left( \begin{array}{l} \text{Rate of change of} \\ \text{the energy content} \\ \text{of the element} \end{array} \right)$$

or

$$\dot{Q}_{\text{cond, left}} + \dot{Q}_{\text{cond, top}} + \dot{Q}_{\text{cond, right}} + \dot{Q}_{\text{cond, bottom}} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} = 0 \quad (5-31)$$

for the *steady* case. Again assuming the temperatures between the adjacent nodes to vary linearly and noting that the heat transfer area is  $A_x = \Delta y \times 1 = \Delta y$  in the  $x$ -direction and  $A_y = \Delta x \times 1 = \Delta x$  in the  $y$ -direction, the energy balance relation above becomes

$$\begin{aligned} k\Delta y \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k\Delta x \frac{T_{m,n+1} - T_{m,n}}{\Delta y} + k\Delta y \frac{T_{m+1,n} - T_{m,n}}{\Delta x} \\ + k\Delta x \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + \dot{e}_{m,n} \Delta x \Delta y = 0 \end{aligned} \quad (5-32)$$

Dividing each term by  $\Delta x \times \Delta y$  and simplifying gives

$$\frac{T_{m-1,n} - 2T_{m,n} + T_{m+1,n}}{\Delta x^2} + \frac{T_{m,n-1} - 2T_{m,n} + T_{m,n+1}}{\Delta y^2} + \frac{\dot{e}_{m,n}}{k} = 0 \quad (5-33)$$

FIGURE 5-23

The nodal network for the finite difference formulation of two-dimensional conduction in rectangular coordinates.

FIGURE 5-24

The volume element of a general interior node  $(m, n)$  for two-dimensional conduction in rectangular coordinates.

for  $m = 1, 2, 3, \dots, M - 1$  and  $n = 1, 2, 3, \dots, N - 1$ . This equation is identical to Eq. 5–12 obtained earlier by replacing the derivatives in the differential equation by differences for an interior node ( $m, n$ ). Again a rectangular region  $M$  equally spaced nodes in the  $x$ -direction and  $N$  equally spaced nodes in the  $y$ -direction has a total of  $(M + 1)(N + 1)$  nodes, and Eq. 5–33 can be used to obtain the finite difference equations at all interior nodes.

In finite difference analysis, usually a **square mesh** is used for simplicity (except when the magnitudes of temperature gradients in the  $x$ - and  $y$ -directions are very different), and thus  $\Delta x$  and  $\Delta y$  are taken to be the same. Then  $\Delta x = \Delta y = l$ , and the relation above simplifies to

$$T_{m-1,n} + T_{m+1,n} + T_{m,n+1} + T_{m,n-1} - 4T_{m,n} + \frac{\dot{e}_{m,n}l^2}{k} = 0 \quad (5-34)$$

That is, the finite difference formulation of an interior node is obtained by *adding the temperatures of the four nearest neighbors of the node, subtracting four times the temperature of the node itself, and adding the heat generation term*. It can also be expressed in this form, which is easy to remember:

$$T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}} - 4T_{\text{node}} + \frac{\dot{e}_{\text{node}}l^2}{k} = 0 \quad (5-35)$$

When there is no heat generation in the medium, the finite difference equation for an interior node further simplifies to  $T_{\text{node}} = (T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}})/4$ , which has the interesting interpretation that the temperature of each interior node is the arithmetic average of the temperatures of the four neighboring nodes. This statement is also true for the three-dimensional problems except that the interior nodes in that case will have six neighboring nodes instead of four.

## Boundary Nodes

The development of finite difference formulation of *boundary nodes* in two- (or three-) dimensional problems is similar to the development in the one-dimensional case discussed earlier. Again, the region is partitioned between the nodes by forming *volume elements* around the nodes, and an *energy balance* is written for each boundary node. Various boundary conditions can be handled as discussed for a plane wall, except that the volume elements in the two-dimensional case involve heat transfer in the  $y$ -direction as well as the  $x$ -direction. Insulated surfaces can still be viewed as “mirrors,” and the mirror image concept can be used to treat nodes on insulated boundaries as interior nodes.

For heat transfer under *steady* conditions, the basic equation to keep in mind when writing an *energy balance* on a volume element is (Fig. 5–25)

$$\sum_{\text{All sides}} \dot{Q} + \dot{e}V_{\text{element}} = 0 \quad (5-36)$$

**FIGURE 5–25**

The finite difference formulation of a boundary node is obtained by writing an energy balance on its volume element.

whether the problem is one-, two-, or three-dimensional. Again we assume, for convenience in formulation, all heat transfer to be *into* the volume element from all surfaces except for specified heat flux, whose direction is already specified. This is demonstrated in Example 5–3 for various boundary conditions.

**EXAMPLE 5-3** Steady Two-Dimensional Heat Conduction in L-Bars

Consider steady heat transfer in an L-shaped solid body whose cross section is given in Figure 5-26. Heat transfer in the direction normal to the plane of the paper is negligible, and thus heat transfer in the body is two-dimensional. The thermal conductivity of the body is  $k = 15 \text{ W/m}\cdot\text{K}$ , and heat is generated in the body at a rate of  $\dot{e} = 2 \times 10^6 \text{ W/m}^3$ . The left surface of the body is insulated, and the bottom surface is maintained at a uniform temperature of  $90^\circ\text{C}$ . The entire top surface is subjected to convection to ambient air at  $T_\infty = 25^\circ\text{C}$  with a convection coefficient of  $h = 80 \text{ W/m}^2\cdot\text{K}$ , and the right surface is subjected to heat flux at a uniform rate of  $\dot{q}_R = 5000 \text{ W/m}^2$ . The nodal network of the problem consists of 15 equally spaced nodes with  $\Delta x = \Delta y = 1.2 \text{ cm}$ , as shown in the figure. Five of the nodes are at the bottom surface, and thus their temperatures are known. Obtain the finite difference equations at the remaining nine nodes and determine the nodal temperatures by solving them.

**SOLUTION** Heat transfer in a long L-shaped solid bar with specified boundary conditions is considered. The nine unknown nodal temperatures are to be determined with the finite difference method.

**Assumptions** 1 Heat transfer is steady and two-dimensional, as stated. 2 Thermal conductivity is constant. 3 Heat generation is uniform. 4 Radiation heat transfer is negligible.

**Properties** The thermal conductivity is given to be  $k = 15 \text{ W/m}\cdot\text{K}$ .

**Analysis** We observe that all nodes are boundary nodes except node 5, which is an interior node. Therefore, we have to rely on energy balances to obtain the finite difference equations. But first we form the volume elements by partitioning the region among the nodes equitably by drawing dashed lines between the nodes. If we consider the volume element represented by an interior node to be *full size* (i.e.,  $\Delta x \times \Delta y \times 1$ ), then the element represented by a regular boundary node such as node 2 becomes *half size* (i.e.,  $\Delta x \times \Delta y/2 \times 1$ ), and a corner node such as node 1 is *quarter size* (i.e.,  $\Delta x/2 \times \Delta y/2 \times 1$ ). Keeping Eq. 5-36 in mind for the energy balance, the finite difference equations for each of the nine nodes are obtained as follows:

(a) Node 1. The volume element of this corner node is insulated on the left and subjected to convection at the top and to conduction at the right and bottom surfaces. An energy balance on this element gives (Fig. 5-27a)

$$0 + h \frac{\Delta x}{2} (T_\infty - T_1) + k \frac{\Delta y}{2} \frac{T_2 - T_1}{\Delta x} + k \frac{\Delta x}{2} \frac{T_4 - T_1}{\Delta y} + \dot{e}_1 \frac{\Delta x}{2} \frac{\Delta y}{2} = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$-\left(2 + \frac{hl}{k}\right) T_1 + T_2 + T_4 = -\frac{hl}{k} T_\infty - \frac{\dot{e}_1 l^2}{2k}$$

(b) Node 2. The volume element of this boundary node is subjected to convection at the top and to conduction at the right, bottom, and left surfaces. An energy balance on this element gives (Fig. 5-27b)

$$h \Delta x (T_\infty - T_2) + k \frac{\Delta y}{2} \frac{T_3 - T_2}{\Delta x} + k \Delta x \frac{T_5 - T_2}{\Delta y} + k \frac{\Delta y}{2} \frac{T_1 - T_2}{\Delta x} + \dot{e}_2 \Delta x \frac{\Delta y}{2} = 0$$

**FIGURE 5-26**

Schematic for Example 5-3 and the nodal network (the boundaries of volume elements of the nodes are indicated by dashed lines).

**FIGURE 5-27**

Schematics for energy balances on the volume elements of nodes 1 and 2.

**FIGURE 5–28**

Schematics for energy balances on the volume elements of nodes 3 and 4.

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$T_1 - \left(4 + \frac{2hl}{k}\right)T_2 + T_3 + 2T_5 = -\frac{2hl}{k}T_\infty - \frac{\dot{e}_2 l^2}{k}$$

(c) Node 3. The volume element of this corner node is subjected to convection at the top and right surfaces and to conduction at the bottom and left surfaces. An energy balance on this element gives (Fig. 5–28a)

$$h\left(\frac{\Delta x}{2} + \frac{\Delta y}{2}\right)(T_\infty - T_3) + k \frac{\Delta x}{2} \frac{T_6 - T_3}{\Delta y} + k \frac{\Delta y}{2} \frac{T_2 - T_3}{\Delta x} + \dot{e}_3 \frac{\Delta x}{2} \frac{\Delta y}{2} = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$T_2 - \left(2 + \frac{2hl}{k}\right)T_3 + T_6 = -\frac{2hl}{k}T_\infty - \frac{\dot{e}_3 l^2}{2k}$$

(d) Node 4. This node is on the insulated boundary and can be treated as an interior node by replacing the insulation by a mirror. This puts a reflected image of node 5 to the left of node 4. Noting that  $\Delta x = \Delta y = l$ , the general interior node relation for the steady two-dimensional case (Eq. 5–35) gives (Fig. 5–28b)

$$T_5 + T_1 + T_5 + T_{10} - 4T_4 + \frac{\dot{e}_4 l^2}{k} = 0$$

or, noting that  $T_{10} = 90^\circ\text{C}$ ,

$$T_1 - 4T_4 + 2T_5 = -90 - \frac{\dot{e}_4 l^2}{k}$$

(e) Node 5. This is an interior node, and noting that  $\Delta x = \Delta y = l$ , the finite difference formulation of this node is obtained directly from Eq. 5–35 to be (Fig. 5–29a)

$$T_4 + T_2 + T_6 + T_{11} - 4T_5 + \frac{\dot{e}_5 l^2}{k} = 0$$

or, noting that  $T_{11} = 90^\circ\text{C}$ ,

$$T_2 + T_4 - 4T_5 + T_6 = -90 - \frac{\dot{e}_5 l^2}{k}$$

(f) Node 6. The volume element of this inner corner node is subjected to convection at the L-shaped exposed surface and to conduction at other surfaces. An energy balance on this element gives (Fig. 5–29b)

$$\begin{aligned} h\left(\frac{\Delta x}{2} + \frac{\Delta y}{2}\right)(T_\infty - T_6) + k \frac{\Delta y}{2} \frac{T_7 - T_6}{\Delta x} + k \Delta x \frac{T_{12} - T_6}{\Delta y} \\ + k \Delta y \frac{T_5 - T_6}{\Delta x} + k \frac{\Delta x}{2} \frac{T_3 - T_6}{\Delta y} + \dot{e}_6 \frac{3\Delta x\Delta y}{4} = 0 \end{aligned}$$

**FIGURE 5–29**

Schematics for energy balances on the volume elements of nodes 5 and 6.

Taking  $\Delta x = \Delta y = l$  and noting that  $T_{12} = 90^\circ\text{C}$ , it simplifies to

$$T_3 + 2T_5 - \left(6 + \frac{2hl}{k}\right)T_6 + T_7 = -180 - \frac{2hl}{k}T_\infty - \frac{3\dot{e}_6l^2}{2k}$$

(g) Node 7. The volume element of this boundary node is subjected to convection at the top and to conduction at the right, bottom, and left surfaces. An energy balance on this element gives (Fig. 5–30a)

$$\begin{aligned} h\Delta x(T_\infty - T_7) + k \frac{\Delta y}{2} \frac{T_8 - T_7}{\Delta x} + k\Delta x \frac{T_{13} - T_7}{\Delta y} \\ + k \frac{\Delta y}{2} \frac{T_6 - T_7}{\Delta x} + \dot{e}_7\Delta x \frac{\Delta y}{2} = 0 \end{aligned}$$

Taking  $\Delta x = \Delta y = l$  and noting that  $T_{13} = 90^\circ\text{C}$ , it simplifies to

$$T_6 - \left(4 + \frac{2hl}{k}\right)T_7 + T_8 = -180 - \frac{2hl}{k}T_\infty - \frac{\dot{e}_7l^2}{k}$$

(h) Node 8. This node is identical to node 7, and the finite difference formulation of this node can be obtained from that of node 7 by shifting the node numbers by 1 (i.e., replacing subscript  $m$  by  $m + 1$ ). It gives

$$T_7 - \left(4 + \frac{2hl}{k}\right)T_8 + T_9 = -180 - \frac{2hl}{k}T_\infty - \frac{\dot{e}_8l^2}{k}$$

(i) Node 9. The volume element of this corner node is subjected to convection at the top surface, to heat flux at the right surface, and to conduction at the bottom and left surfaces. An energy balance on this element gives (Fig. 5–30b)

$$h \frac{\Delta x}{2} (T_\infty - T_9) + \dot{q}_R \frac{\Delta y}{2} + k \frac{\Delta x}{2} \frac{T_{15} - T_9}{\Delta y} + k \frac{\Delta y}{2} \frac{T_8 - T_9}{\Delta x} + \dot{e}_9 \frac{\Delta x}{2} \frac{\Delta y}{2} = 0$$

Taking  $\Delta x = \Delta y = l$  and noting that  $T_{15} = 90^\circ\text{C}$ , it simplifies to

$$T_8 - \left(2 + \frac{hl}{k}\right)T_9 = -90 - \frac{\dot{q}_R l}{k} - \frac{hl}{k}T_\infty - \frac{\dot{e}_9 l^2}{2k}$$

This completes the development of finite difference formulation for this problem. Substituting the given quantities, the system of nine equations for the determination of nine unknown nodal temperatures becomes

$$\begin{aligned} -2.064T_1 + T_2 + T_4 &= -11.2 \\ T_1 - 4.128T_2 + T_3 + 2T_5 &= -22.4 \\ T_2 - 2.128T_3 + T_6 &= -12.8 \\ T_1 - 4T_4 + 2T_5 &= -109.2 \\ T_2 + T_4 - 4T_5 + T_6 &= -109.2 \\ T_3 + 2T_5 - 6.128T_6 + T_7 &= -212.0 \end{aligned}$$

**FIGURE 5–30**

Schematics for energy balances on the volume elements of nodes 7 and 9.

$$T_6 - 4.128T_7 + T_8 = -202.4$$

$$T_7 - 4.128T_8 + T_9 = -202.4$$

$$T_8 - 2.064T_9 = -105.2$$

which is a system of nine algebraic equations with nine unknowns. Using an equation solver, its solution is determined to be

$$T_1 = 112.1^\circ\text{C} \quad T_2 = 110.8^\circ\text{C} \quad T_3 = 106.6^\circ\text{C}$$

$$T_4 = 109.4^\circ\text{C} \quad T_5 = 108.1^\circ\text{C} \quad T_6 = 103.2^\circ\text{C}$$

$$T_7 = 97.3^\circ\text{C} \quad T_8 = 96.3^\circ\text{C} \quad T_9 = 97.6^\circ\text{C}$$

Note that the temperature is the highest at node 1 and the lowest at node 8. This is consistent with our expectations since node 1 is the farthest away from the bottom surface, which is maintained at  $90^\circ\text{C}$  and has one side insulated, and node 8 has the largest exposed area relative to its volume while being close to the surface at  $90^\circ\text{C}$ .

**FIGURE 5-31**

Approximating an irregular boundary with a rectangular mesh.

## Irregular Boundaries

In problems with simple geometries, we can fill the entire region using simple volume elements such as strips for a plane wall and rectangular elements for two-dimensional conduction in a rectangular region. We can also use cylindrical or spherical shell elements to cover the cylindrical and spherical bodies entirely. However, many geometries encountered in practice such as turbine blades or engine blocks do not have simple shapes, and it is difficult to fill such geometries having irregular boundaries with simple volume elements. A practical way of dealing with such geometries is to replace the irregular geometry by a series of simple volume elements, as shown in Figure 5-31. This simple approach is often satisfactory for practical purposes, especially when the nodes are closely spaced near the boundary. More sophisticated approaches are available for handling irregular boundaries, and they are commonly incorporated into the commercial software packages.

### EXAMPLE 5-4

### Heat Loss through Chimneys

Hot combustion gases of a furnace are flowing through a square chimney made of concrete ( $k = 1.4 \text{ W/m}\cdot\text{K}$ ). The flow section of the chimney is  $20 \text{ cm} \times 20 \text{ cm}$ , and the thickness of the wall is  $20 \text{ cm}$ . The average temperature of the hot gases in the chimney is  $T_i = 300^\circ\text{C}$ , and the average convection heat transfer coefficient inside the chimney is  $h_i = 70 \text{ W/m}^2\cdot\text{K}$ . The chimney is losing heat from its outer surface to the ambient air at  $T_o = 20^\circ\text{C}$  by convection with a heat transfer coefficient of  $h_o = 21 \text{ W/m}^2\cdot\text{K}$  and to the sky by radiation. The emissivity of the outer surface of the wall is  $\varepsilon = 0.9$ , and the effective sky temperature is estimated to be  $260 \text{ K}$ . Using the finite difference method with  $\Delta x = \Delta y = 10 \text{ cm}$  and taking full advantage of symmetry, determine the temperatures at the nodal points of a cross section and the rate of heat loss for a 1-m-long section of the chimney.

**SOLUTION** Heat transfer through a square chimney is considered. The nodal temperatures and the rate of heat loss per unit length are to be determined with the finite difference method.

**Assumptions** 1 Heat transfer is steady since there is no indication of change with time. 2 Heat transfer through the chimney is two-dimensional since the height of the chimney is large relative to its cross section, and thus heat conduction through the chimney in the axial direction is negligible. It is tempting to simplify the problem further by considering heat transfer in each wall to be one-dimensional, which would be the case if the walls were thin and thus the corner effects were negligible. This assumption cannot be justified in this case since the walls are very thick and the corner sections constitute a considerable portion of the chimney structure. 3 Thermal conductivity is constant.

**Properties** The properties of chimney are given to be  $k = 1.4 \text{ W/m}\cdot\text{K}$  and  $\epsilon = 0.9$ .

**Analysis** The cross section of the chimney is given in Figure 5–32. The most striking aspect of this problem is the apparent symmetry about the horizontal and vertical lines passing through the midpoint of the chimney as well as the diagonal axes, as indicated on the figure. Therefore, we need to consider only one-eighth of the geometry in the solution whose nodal network consists of nine equally spaced nodes.

No heat can cross a symmetry line, and thus symmetry lines can be treated as insulated surfaces and thus “mirrors” in the finite difference formulation. Then the nodes in the middle of the symmetry lines can be treated as interior nodes by using mirror images. Six of the nodes are boundary nodes, so we have to write energy balances to obtain their finite difference formulations. First we partition the region among the nodes equitably by drawing dashed lines between the nodes through the middle. Then the region around a node surrounded by the boundary or the dashed lines represents the volume element of the node. Considering a unit depth and using the energy balance approach for the boundary nodes (again assuming all heat transfer into the volume element for convenience) and the formula for the interior nodes, the finite difference equations for the nine nodes are determined as follows:

(a) Node 1. On the inner boundary, subjected to convection, Figure 5–33a

$$0 + h_i \frac{\Delta x}{2} (T_i - T_1) + k \frac{\Delta y}{2} \frac{T_2 - T_1}{\Delta x} + k \frac{\Delta x}{2} \frac{T_3 - T_1}{\Delta y} + 0 = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$-\left(2 + \frac{h_i l}{k}\right) T_1 + T_2 + T_3 = -\frac{h_i l}{k} T_i$$

(b) Node 2. On the inner boundary, subjected to convection, Figure 5–33b

$$k \frac{\Delta y}{2} \frac{T_1 - T_2}{\Delta x} + h_i \frac{\Delta x}{2} (T_i - T_2) + 0 + k \Delta x \frac{T_4 - T_2}{\Delta y} = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$T_1 - \left(3 + \frac{h_i l}{k}\right) T_2 + 2T_4 = -\frac{h_i l}{k} T_i$$

FIGURE 5-32

Schematic of the chimney discussed in Example 5–4 and the nodal network for a representative section.

FIGURE 5-33

**FIGURE 5-34**

Converting the boundary nodes 3 and 5 on symmetry lines to interior nodes by using mirror images.

**FIGURE 5-35**

Schematics for energy balances on the volume elements of nodes 7 and 9.

(c) Nodes 3, 4, and 5. (Interior nodes, Fig. 5-34)

$$\text{Node 3: } T_4 + T_1 + T_4 + T_6 - 4T_3 = 0$$

$$\text{Node 4: } T_3 + T_2 + T_5 + T_7 - 4T_4 = 0$$

$$\text{Node 5: } T_4 + T_4 + T_8 + T_8 - 4T_5 = 0$$

(d) Node 6. (On the outer boundary, subjected to convection and radiation)

$$0 + k \frac{\Delta x}{2} \frac{T_3 - T_6}{\Delta y} + k \frac{\Delta y}{2} \frac{T_7 - T_6}{\Delta x} \\ + h_o \frac{\Delta x}{2} (T_o - T_6) + \varepsilon \sigma \frac{\Delta x}{2} (T_{\text{sky}}^4 - T_6^4) = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$T_2 + T_3 - \left( 2 + \frac{h_o l}{k} \right) T_6 = -\frac{h_o l}{k} T_o - \frac{\varepsilon \sigma l}{k} (T_{\text{sky}}^4 - T_6^4)$$

(e) Node 7. (On the outer boundary, subjected to convection and radiation, Fig. 5-35)

$$k \frac{\Delta y}{2} \frac{T_6 - T_7}{\Delta x} + k \Delta x \frac{T_4 - T_7}{\Delta y} + k \frac{\Delta y}{2} \frac{T_8 - T_7}{\Delta x} \\ + h_o \Delta x (T_o - T_7) + \varepsilon \sigma \Delta x (T_{\text{sky}}^4 - T_7^4) = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$2T_4 + T_6 - \left( 4 + \frac{2h_o l}{k} \right) T_7 + T_8 = -\frac{2h_o l}{k} T_o - \frac{2\varepsilon \sigma l}{k} (T_{\text{sky}}^4 - T_7^4)$$

(f) Node 8. Same as node 7, except shift the node numbers up by 1 (replace 4 by 5, 6 by 7, 7 by 8, and 8 by 9 in the last relation)

$$2T_5 + T_7 - \left( 4 + \frac{2h_o l}{k} \right) T_8 + T_9 = -\frac{2h_o l}{k} T_o - \frac{2\varepsilon \sigma l}{k} (T_{\text{sky}}^4 - T_8^4)$$

(g) Node 9. (On the outer boundary, subjected to convection and radiation, Fig. 5-35)

$$k \frac{\Delta y}{2} \frac{T_8 - T_9}{\Delta x} + 0 + h_o \frac{\Delta x}{2} (T_o - T_9) + \varepsilon \sigma \frac{\Delta x}{2} (T_{\text{sky}}^4 - T_9^4) = 0$$

Taking  $\Delta x = \Delta y = l$ , it simplifies to

$$T_8 - \left( 1 + \frac{h_o l}{k} \right) T_9 = -\frac{h_o l}{k} T_o - \frac{\varepsilon \sigma l}{k} (T_{\text{sky}}^4 - T_9^4)$$

This problem involves radiation, which requires the use of absolute temperature, and thus all temperatures should be expressed in Kelvin. Alternately, we could use °C for all temperatures provided that the four temperatures in the radiation

terms are expressed in the form  $(T + 273)^4$ . Substituting the given quantities, the system of nine equations for the determination of nine unknown nodal temperatures in a form suitable for use with an iteration method becomes

$$\begin{aligned} T_1 &= (T_2 + T_3 + 2865)/7 \\ T_2 &= (T_1 + 2T_4 + 2865)/8 \\ T_3 &= (T_1 + 2T_4 + T_6)/4 \\ T_4 &= (T_2 + T_3 + T_5 + T_7)/4 \\ T_5 &= (2T_4 + 2T_8)/4 \\ T_6 &= (T_2 + T_3 + 456.2 - 0.3645 \times 10^{-9} T_6^4)/3.5 \\ T_7 &= (2T_4 + T_6 + T_8 + 912.4 - 0.729 \times 10^{-9} T_7^4)/7 \\ T_8 &= (2T_5 + T_7 + T_9 + 912.4 - 0.729 \times 10^{-9} T_8^4)/7 \\ T_9 &= (T_8 + 456.2 - 0.3645 \times 10^{-9} T_9^4)/2.5 \end{aligned}$$

which is a system of *nonlinear* equations. Using the Gauss-Seidel iteration method or an equation solver, its solution is determined to be

$$\begin{aligned} T_1 &= 545.7 \text{ K} = 272.6^\circ\text{C} & T_2 &= 529.2 \text{ K} = 256.1^\circ\text{C} & T_3 &= 425.2 \text{ K} = 152.1^\circ\text{C} \\ T_4 &= 411.2 \text{ K} = 138.0^\circ\text{C} & T_5 &= 362.1 \text{ K} = 89.0^\circ\text{C} & T_6 &= 332.9 \text{ K} = 59.7^\circ\text{C} \\ T_7 &= 328.1 \text{ K} = 54.9^\circ\text{C} & T_8 &= 313.1 \text{ K} = 39.9^\circ\text{C} & T_9 &= 296.5 \text{ K} = 23.4^\circ\text{C} \end{aligned}$$

The variation of temperature in the chimney is shown in Figure 5–36.

Note that the temperatures are highest at the inner wall (but less than 300°C) and lowest at the outer wall (but more than 260 K), as expected.

The average temperature at the outer surface of the chimney weighed by the surface area is

$$\begin{aligned} T_{\text{wall, out}} &= \frac{(0.5T_6 + T_7 + T_8 + 0.5T_9)}{(0.5 + 1 + 1 + 0.5)} \\ &= \frac{0.5 \times 332.9 + 328.1 + 313.1 + 0.5 \times 296.5}{3} = 318.6 \text{ K} \end{aligned}$$

Then the rate of heat loss through the 1-m-long section of the chimney can be determined approximately from

$$\begin{aligned} \dot{Q}_{\text{chimney}} &= h_o A_o (T_{\text{wall, out}} - T_o) + \epsilon \sigma A_o (T_{\text{wall, out}}^4 - T_{\text{sky}}^4) \\ &= (21 \text{ W/m}^2 \cdot \text{K})[4 \times (0.6 \text{ m})(1 \text{ m})](318.6 - 293)\text{K} \\ &\quad + 0.9(5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4) [4 \times (0.6 \text{ m})(1 \text{ m})](318.6 \text{ K})^4 - (260 \text{ K})^4] \\ &= 1291 + 702 = 1993 \text{ W} \end{aligned}$$

We could also determine the heat transfer by finding the average temperature of the inner wall, which is  $(272.6 + 256.1)/2 = 264.4^\circ\text{C}$ , and applying Newton's law of cooling at that surface:

$$\begin{aligned} \dot{Q}_{\text{chimney}} &= h_i A_i (T_i - T_{\text{wall, in}}) \\ &= (70 \text{ W/m}^2 \cdot \text{K})[4 \times (0.2 \text{ m})(1 \text{ m})](300 - 264.4)^\circ\text{C} = 1994 \text{ W} \end{aligned}$$

**FIGURE 5–36**

The variation of temperature in the chimney.

The difference between the two results is due to the approximate nature of the numerical analysis.

**Discussion** We used a relatively crude numerical model to solve this problem to keep the complexities at a manageable level. The accuracy of the solution obtained can be improved by using a finer mesh and thus a greater number of nodes. Also, when radiation is involved, it is more accurate (but more laborious) to determine the heat losses for each node and add them up instead of using the average temperature.

## 5–5 ▪ TRANSIENT HEAT CONDUCTION

So far in this chapter we have applied the finite difference method to *steady* heat transfer problems. In this section we extend the method to solve *transient* problems.

We applied the finite difference method to steady problems by *discretizing* the problem in the space variables and solving for temperatures at *discrete* points called the nodes. The solution obtained is valid for any time since under steady conditions the temperatures do not change with time. In transient problems, however, the temperatures change with time as well as position, and thus the finite difference solution of transient problems requires *discretization in time* in addition to discretization in space, as shown in Figure 5–37. This is done by selecting a suitable time step  $\Delta t$  and solving for the unknown nodal temperatures repeatedly for each  $\Delta t$  until the solution at the desired time is obtained. For example, consider a hot metal object that is taken out of the oven at an initial temperature of  $T_i$  at time  $t = 0$  and is allowed to cool in ambient air. If a time step of  $\Delta t = 5$  min is chosen, the determination of the temperature distribution in the metal piece after 3 h requires the determination of the temperatures  $3 \times 60/5 = 36$  times, or in 36 time steps. Therefore, the computation time of this problem is 36 times that of a steady problem. Choosing a smaller  $\Delta t$  increases the accuracy of the solution, but it also increases the computation time.

In transient problems, the *superscript i* is used as the *index* or *counter* of time steps, with  $i = 0$  corresponding to the specified initial condition. In the case of the hot metal piece discussed above,  $i = 1$  corresponds to  $t = 1 \times \Delta t = 5$  min,  $i = 2$  corresponds to  $t = 2 \times \Delta t = 10$  min, and a general time step  $i$  corresponds to  $t_i = i\Delta t$ . The notation  $T_m^i$  is used to represent the temperature at the node  $m$  at time step  $i$ .

The formulation of transient heat conduction problems differs from that of steady ones in that the transient problems involve an *additional term* representing the *change in the energy content* of the medium with time. This additional term appears as a first derivative of temperature with respect to time in the differential equation, and as a change in the internal energy content during  $\Delta t$  in the energy balance formulation. The nodes and the volume elements in transient problems are selected as they are in the steady case, and, again assuming all heat transfer is *into* the element for convenience, the energy balance on a volume element during a time interval  $\Delta t$  can be expressed as

$$\left( \begin{array}{l} \text{Heat transferred into} \\ \text{the volume element} \\ \text{from all of its surfaces} \\ \text{during } \Delta t \end{array} \right) + \left( \begin{array}{l} \text{Heat generated} \\ \text{within the} \\ \text{volume element} \\ \text{during } \Delta t \end{array} \right) = \left( \begin{array}{l} \text{The change in the} \\ \text{energy content of} \\ \text{the volume element} \\ \text{during } \Delta t \end{array} \right)$$

FIGURE 5–37

Finite difference formulation of time-dependent problems involves discrete points in time as well as space.

or

$$\Delta t \times \sum_{\text{All sides}} \dot{Q} + \Delta t \times \dot{E}_{\text{gen, element}} = \Delta E_{\text{element}} \quad (5-37)$$

where the rate of heat transfer  $\dot{Q}$  normally consists of conduction terms for interior nodes, but may involve convection, heat flux, and radiation for boundary nodes.

Noting that  $\Delta E_{\text{element}} = mc_p \Delta T = \rho V_{\text{element}} c_p \Delta T$ , where  $\rho$  is density and  $c_p$  is the specific heat of the element, dividing the earlier relation by  $\Delta t$  gives

$$\sum_{\text{All sides}} \dot{Q} + \dot{E}_{\text{gen, element}} = \frac{\Delta E_{\text{element}}}{\Delta t} = \rho V_{\text{element}} c_p \frac{\Delta T}{\Delta t} \quad (5-38)$$

or, for any node  $m$  in the medium and its volume element,

$$\sum_{\text{All sides}} \dot{Q} + \dot{E}_{\text{gen, element}} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad (5-39)$$

where  $T_m^i$  and  $T_m^{i+1}$  are the temperatures of node  $m$  at times  $t_i = i\Delta t$  and  $t_{i+1} = (i+1)\Delta t$ , respectively, and  $T_m^{i+1} - T_m^i$  represents the temperature change of the node during the time interval  $\Delta t$  between the time steps  $i$  and  $i+1$  (Fig. 5-38).

Note that the ratio  $(T_m^{i+1} - T_m^i)/\Delta t$  is simply the finite difference approximation of the partial derivative  $\partial T/\partial t$  that appears in the differential equations of transient problems. Therefore, we would obtain the same result for the finite difference formulation if we followed a strict mathematical approach instead of the energy balance approach used above. Also note that the finite difference formulations of steady and transient problems differ by the single term on the right side of the equal sign, and the format of that term remains the same in all coordinate systems regardless of whether heat transfer is one-, two-, or three-dimensional. For the special case of  $T_m^{i+1} = T_m^i$  (i.e., no change in temperature with time), the formulation reduces to that of steady case, as expected.

The nodal temperatures in transient problems normally change during each time step, and you may be wondering whether to use temperatures at the *previous* time step  $i$  or the *new* time step  $i+1$  for the terms on the left side of Eq. 5-39. Well, both are reasonable approaches and both are used in practice. The finite difference approach is called the **explicit method** in the first case and the **implicit method** in the second case, and they are expressed in the general form as (Fig. 5-39)

*Explicit method:* 
$$\sum_{\text{All sides}} \dot{Q}^i + \dot{E}_{\text{gen, element}}^i = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad (5-40)$$

*Implicit method:* 
$$\sum_{\text{All sides}} \dot{Q}^{i+1} + \dot{E}_{\text{gen, element}}^{i+1} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad (5-41)$$

It appears that the time derivative is expressed in *forward difference* form in the explicit case and *backward difference* form in the implicit case. Of course, it is also possible to mix the two fundamental formulations of Eqs. 5-40

FIGURE 5-38

The change in the energy content of the volume element of a node during a time interval  $\Delta t$ .

If expressed at  $i+1$ : Implicit method

$$\sum_{\text{All sides}} \dot{Q}^{i+1} + \dot{E}_{\text{gen, element}}^{i+1} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

If expressed at  $i$ : Explicit method

FIGURE 5-39

The formulation of explicit and implicit methods differs at the time step (previous or new) at which the heat transfer and heat generation terms are expressed.

and 5–41 and come up with more elaborate formulations, but such formulations offer little insight and are beyond the scope of this text. Note that both formulations are simply expressions between the nodal temperatures before and after a time interval and are based on determining the new temperatures  $T_m^{i+1}$  using the previous temperatures  $T_m^i$ . The explicit and implicit formulations given here are quite general and can be used in any coordinate system regardless of the dimension of heat transfer. The volume elements in multi-dimensional cases simply have more surfaces and thus involve more terms in the summation.

The explicit and implicit methods have their advantages and disadvantages, and one method is not necessarily better than the other one. Next you will see that the *explicit method* is easy to implement but imposes a limit on the allowable time step to avoid instabilities in the solution, and the *implicit method* requires the nodal temperatures to be solved simultaneously for each time step but imposes no limit on the magnitude of the time step. We limit the discussion to one- and two-dimensional cases to keep the complexities at a manageable level, but the analysis can readily be extended to three-dimensional cases and other coordinate systems.

**FIGURE 5-40**

The nodal points and volume elements for the transient finite difference formulation of one-dimensional conduction in a plane wall.

## Transient Heat Conduction in a Plane Wall

Consider transient one-dimensional heat conduction in a plane wall of thickness  $L$  with heat generation  $\dot{e}(x, t)$  that may vary with time and position and constant conductivity  $k$  with a mesh size of  $\Delta x = L/M$  and nodes  $0, 1, 2, \dots, M$  in the  $x$ -direction, as shown in Figure 5–40. Noting that the volume element of a general interior node  $m$  involves heat conduction from two sides and the volume of the element is  $V_{\text{element}} = A\Delta x$ , the transient finite difference formulation for an interior node can be expressed on the basis of Eq. 5–39 as

$$kA \frac{T_{m-1}^i - T_m^i}{\Delta x} + kA \frac{T_{m+1}^i - T_m^i}{\Delta x} + \dot{e}_m A \Delta x = \rho A \Delta x c_p \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad (5-42)$$

Canceling the surface area  $A$  and multiplying by  $\Delta x/k$ , it simplifies to

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{e}_m \Delta x^2}{k} = \frac{\Delta x^2}{\alpha \Delta t} (T_m^{i+1} - T_m^i) \quad (5-43)$$

where  $\alpha = k/\rho c_p$  is the *thermal diffusivity* of the wall material. We now define a dimensionless **mesh Fourier number** as

$$\tau = \frac{\alpha \Delta t}{\Delta x^2} \quad (5-44)$$

Then Eq. 5–43 reduces to

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{e}_m \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad (5-45)$$

Note that the left side of this equation is simply the finite difference formulation of the problem for the steady case. This is not surprising since the formulation must reduce to the steady case for  $T_m^{i+1} = T_m^i$ . Also, we are still not

committed to explicit or implicit formulation since we did not indicate the time step on the left side of the equation. We now obtain the *explicit* finite difference formulation by expressing the left side at time step  $i$  as

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{e}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad (\text{explicit}) \quad (5-46)$$

This equation can be solved *explicitly* for the new temperature  $T_m^{i+1}$  (and thus the name *explicit* method) to give

$$T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1 - 2\tau) T_m^i + \tau \frac{\dot{e}_m^i \Delta x^2}{k} \quad (5-47)$$

for all interior nodes  $m = 1, 2, 3, \dots, M - 1$  in a plane wall. Expressing the left side of Eq. 5-45 at time step  $i + 1$  instead of  $i$  would give the *implicit* finite difference formulation as

$$T_{m-1}^{i+1} - 2T_m^{i+1} + T_{m+1}^{i+1} + \frac{\dot{e}_m^{i+1} \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad (\text{implicit}) \quad (5-48)$$

which can be rearranged as

$$\tau T_{m-1}^{i+1} - (1 + 2\tau) T_m^{i+1} + \tau T_{m+1}^{i+1} + \tau \frac{\dot{e}_m^{i+1} \Delta x^2}{k} + T_m^i = 0 \quad (5-49)$$

The application of either the explicit or the implicit formulation to each of the  $M - 1$  interior nodes gives  $M - 1$  equations. The remaining two equations are obtained by applying the same method to the two boundary nodes unless, of course, the boundary temperatures are specified as constants (invariant with time). For example, the formulation of the convection boundary condition at the left boundary (node 0) for the explicit case can be expressed as (Fig. 5-41)

$$hA(T_\infty - T_0^i) + kA \frac{T_1^i - T_0^i}{\Delta x} + \dot{e}_0^i A \frac{\Delta x}{2} = \rho A \frac{\Delta x}{2} c_p \frac{T_0^{i+1} - T_0^i}{\Delta t} \quad (5-50)$$

which simplifies to

$$T_0^{i+1} = \left( 1 - 2\tau - 2\tau \frac{h\Delta x}{k} \right) T_0^i + 2\tau T_1^i + 2\tau \frac{h\Delta x}{k} T_\infty + \tau \frac{\dot{e}_0^i \Delta x^2}{k} \quad (5-51)$$

Note that in the case of no heat generation and  $\tau = 0.5$ , which is the upper limit of the stability criterion for the one-dimensional explicit method (discussed in the next subsection), the explicit finite difference formulation for a general interior node reduces to  $(T_m^{i+1} = (T_{m-1}^i + T_{m+1}^i)/2$ , which has the interesting interpretation that *the temperature of an interior node at the new time step is simply the average of the temperatures of its neighboring nodes at the previous time step.*

Once the formulation (explicit or implicit) is complete and the initial condition is specified, the solution of a transient problem is obtained by *marching* in time using a step size of  $\Delta t$  as follows: select a suitable time step  $\Delta t$  and determine the nodal temperatures from the initial condition. Taking the initial temperatures as the *previous* solution  $T_m^i$  at  $t = 0$ , obtain the new solution  $T_m^{i+1}$  at all nodes at time

**FIGURE 5-41**

Schematic for the explicit finite difference formulation of the convection condition at the left boundary of a plane wall.

**FIGURE 5-42**

The stability criterion of the explicit method requires all primary coefficients to be positive or zero.

$t = \Delta t$  using the transient finite difference relations. Now using the solution just obtained at  $t = \Delta t$  as the *previous* solution  $T_m^i$ , obtain the new solution  $T_m^{i+1}$  at  $t = 2\Delta t$  using the same relations. Repeat the process until the solution at the desired time is obtained.

### Stability Criterion for Explicit Method: Limitation on $\Delta t$

The explicit method is easy to use, but it suffers from an undesirable feature that severely restricts its utility: the explicit method is not unconditionally stable, and the largest permissible value of the time step  $\Delta t$  is limited by the stability criterion. If the time step  $\Delta t$  is not sufficiently small, the solutions obtained by the explicit method may oscillate wildly and diverge from the actual solution. To avoid such divergent oscillations in nodal temperatures, the value of  $\Delta t$  must be maintained below a certain upper limit established by the **stability criterion**. It can be shown mathematically or by a physical argument based on the second law of thermodynamics that *the stability criterion is satisfied if the coefficients of all  $T_m^i$  in the  $T_m^{i+1}$  expressions (called the primary coefficients) are greater than or equal to zero for all nodes  $m$*  (Fig. 5-42). Of course, all the terms involving  $T_m^i$  for a particular node must be grouped together before this criterion is applied.

Different equations for different nodes may result in different restrictions on the size of the time step  $\Delta t$ , and the criterion that is most restrictive should be used in the solution of the problem. A practical approach is to identify the equation with the *smallest primary coefficient* since it is the most restrictive and to determine the allowable values of  $\Delta t$  by applying the stability criterion to that equation only. A  $\Delta t$  value obtained this way also satisfies the stability criterion for all other equations in the system.

For example, in the case of transient one-dimensional heat conduction in a plane wall with specified surface temperatures, the explicit finite difference equations for all the nodes (which are *interior nodes*) are obtained from Eq. 5-47. The coefficient of  $T_m^i$  in the  $T_m^{i+1}$  expression is  $1 - 2\tau$ , which is independent of the node number  $m$ , and thus the stability criterion for all nodes in this case is  $1 - 2\tau \geq 0$  or

$$\tau = \frac{\alpha \Delta t}{\Delta x^2} \leq \frac{1}{2} \quad \left( \begin{array}{l} \text{interior nodes, one-dimensional heat} \\ \text{transfer in rectangular coordinates} \end{array} \right) \quad (5-52)$$

When the material of the medium and thus its thermal diffusivity  $\alpha$  is known and the value of the mesh size  $\Delta x$  is specified, the largest allowable value of the time step  $\Delta t$  can be determined from this relation. For example, in the case of a brick wall ( $\alpha = 0.45 \times 10^{-6} \text{ m}^2/\text{s}$ ) with a mesh size of  $\Delta x = 0.01 \text{ m}$ , the upper limit of the time step is

$$\Delta t \leq \frac{1}{2} \frac{\Delta x^2}{\alpha} = \frac{(0.01 \text{ m})^2}{2(0.45 \times 10^{-6} \text{ m}^2/\text{s})} = 111 \text{ s} = 1.85 \text{ min}$$

The boundary nodes involving convection and/or radiation are more restrictive than the interior nodes and thus require smaller time steps. Therefore, the most restrictive boundary node should be used in the determination of the maximum allowable time step  $\Delta t$  when a transient problem is solved with the explicit method. For example, the explicit finite difference formulation

for the convection boundary condition at the left boundary (node 0) of the plane wall shown in Fig. 5–41 expressed by Eq. 5–51 is more restrictive than the explicit finite difference formulation for the interior nodes presented by Eq. 5–47. Therefore, in this case the stability criterion for all nodes becomes

$$1 - 2\tau - 2\tau \frac{h\Delta x}{k} \geq 0 \quad \text{or} \quad \tau \leq \frac{1}{2(1 + h\Delta x/k)}$$

To gain a better understanding of the stability criterion, consider the explicit finite difference formulation for an interior node of a plane wall (Eq. 5–47) for the case of no heat generation,

$$T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1 - 2\tau)T_m^i$$

Assume that at some time step  $i$  the temperatures  $T_{m-1}^i$  and  $T_{m+1}^i$  are equal but less than  $T_m^i$  (say,  $T_{m-1}^i = T_{m+1}^i = 50^\circ\text{C}$  and  $T_m^i = 80^\circ\text{C}$ ). At the next time step, we expect the temperature of node  $m$  to be between the two values (say,  $70^\circ\text{C}$ ). However, if the value of  $\tau$  exceeds 0.5 (say,  $\tau = 1$ ), the temperature of node  $m$  at the next time step will be less than the temperature of the neighboring nodes (it will be  $20^\circ\text{C}$ ), which is physically impossible and violates the second law of thermodynamics (Fig. 5–43). Requiring the new temperature of node  $m$  to remain above the temperature of the neighboring nodes is equivalent to requiring the value of  $\tau$  to remain below 0.5.

The implicit method is *unconditionally stable*, and thus we can use any time step we please with that method (of course, the smaller the time step, the better the accuracy of the solution). The disadvantage of the implicit method is that it results in a set of equations that must be solved *simultaneously* for each time step. Both methods are used in practice.

### EXAMPLE 5–5 Transient Heat Conduction in a Large Uranium Plate

Consider a large uranium plate of thickness  $L = 4\text{ cm}$ , thermal conductivity  $k = 28\text{ W/m}\cdot\text{K}$ , and thermal diffusivity  $\alpha = 12.5 \times 10^{-6}\text{ m}^2/\text{s}$  that is initially at a uniform temperature of  $200^\circ\text{C}$ . Heat is generated uniformly in the plate at a constant rate of  $\dot{e} = 5 \times 10^6\text{ W/m}^3$ . At time  $t = 0$ , one side of the plate is brought into contact with iced water and is maintained at  $0^\circ\text{C}$  at all times, while the other side is subjected to convection to an environment at  $T_\infty = 30^\circ\text{C}$  with a heat transfer coefficient of  $h = 45\text{ W/m}^2\cdot\text{K}$ , as shown in Fig. 5–44. Considering a total of three equally spaced nodes in the medium, two at the boundaries and one at the middle, estimate the exposed surface temperature of the plate 2.5 min after the start of cooling using (a) the explicit method and (b) the implicit method.

**SOLUTION** We have solved this problem in Example 5–1 for the steady case, and here we repeat it for the transient case to demonstrate the application of the transient finite difference methods. Again we assume one-dimensional heat transfer in rectangular coordinates and constant thermal conductivity.

**FIGURE 5–43**  
The violation of the stability criterion in the explicit method may result in the violation of the second law of thermodynamics and thus divergence of solution.

**FIGURE 5–44**  
Schematic for Example 5–5.

FIGURE 5-45

Schematic for the explicit finite difference formulation of the convection condition at the right boundary of a plane wall.

The number of nodes is specified to be  $M = 3$ , and they are chosen to be at the two surfaces of the plate and at the middle, as shown in the figure. Then the nodal spacing  $\Delta x$  becomes

$$\Delta x = \frac{L}{M - 1} = \frac{0.04 \text{ m}}{3 - 1} = 0.02 \text{ m}$$

We number the nodes as 0, 1, and 2. The temperature at node 0 is given to be  $T_0 = 0^\circ\text{C}$  at all times, and the temperatures at nodes 1 and 2 are to be determined. This problem involves only two unknown nodal temperatures, and thus we need to have only two equations to determine them uniquely. These equations are obtained by applying the finite difference method to nodes 1 and 2.

(a) Node 1 is an interior node, and the *explicit* finite difference formulation at that node is obtained directly from Eq. 5-47 by setting  $m = 1$ :

$$T_1^{i+1} = \tau(T_0 + T_2^i) + (1 - 2\tau)T_1^i + \tau \frac{\dot{e}_1 \Delta x^2}{k} \quad (a)$$

Node 2 is a boundary node subjected to convection, and the finite difference formulation at that node is obtained by writing an energy balance on the volume element of thickness  $\Delta x/2$  at that boundary by assuming heat transfer to be into the medium at all sides (Fig. 5-45):

$$hA(T_\infty - T_2^i) + kA \frac{T_1^i - T_2^i}{\Delta x} + \dot{e}_2 A \frac{\Delta x}{2} = \rho A \frac{\Delta x}{2} c_p \frac{T_2^{i+1} - T_2^i}{\Delta t}$$

Dividing by  $kA/2\Delta x$  and using the definitions of thermal diffusivity  $\alpha = k/\rho c_p$  and the dimensionless mesh Fourier number  $\tau = \alpha \Delta t / \Delta x^2$  gives

$$\frac{2h\Delta x}{k}(T_\infty - T_2^i) + 2(T_1^i - T_2^i) + \frac{\dot{e}_2 \Delta x^2}{k} = \frac{T_2^{i+1} - T_2^i}{\tau}$$

which can be solved for  $T_2^{i+1}$  to give

$$T_2^{i+1} = \left(1 - 2\tau - 2\tau \frac{h\Delta x}{k}\right) T_2^i + \tau \left(2T_1^i + 2 \frac{h\Delta x}{k} T_\infty + \frac{\dot{e}_2 \Delta x^2}{k}\right) \quad (b)$$

Note that we did not use the superscript  $i$  for quantities that do not change with time. Next we need to determine the upper limit of the time step  $\Delta t$  from the stability criterion, which requires the coefficient of  $T_1^i$  in Equation (a) and the coefficient of  $T_2^i$  in the second equation to be greater than or equal to zero. The coefficient of  $T_2^i$  is smaller in this case, and thus the stability criterion for this problem can be expressed as

$$1 - 2\tau - 2\tau \frac{h\Delta x}{k} \geq 0 \rightarrow \tau \leq \frac{1}{2(1 + h\Delta x/k)} \rightarrow \Delta t \leq \frac{\Delta x^2}{2\alpha(1 + h\Delta x/k)}$$

since  $\tau = \alpha \Delta t / \Delta x^2$ . Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\Delta t \leq \frac{(0.02 \text{ m})^2}{2(12.5 \times 10^{-6} \text{ m}^2/\text{s})[1 + (45 \text{ W/m}^2 \cdot \text{K})(0.02 \text{ m})/28 \text{ W/m} \cdot \text{K}]} = 15.5 \text{ s}$$

Therefore, any time step less than 15.5 s can be used to solve this problem. For convenience, let us choose the time step to be  $\Delta t = 15$  s. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha \Delta t}{\Delta x^2} = \frac{(12.5 \times 10^{-6} \text{ m}^2/\text{s})(15 \text{ s})}{(0.02 \text{ m})^2} = 0.46875 \quad (\text{for } \Delta t = 15 \text{ s})$$

Substituting this value of  $\tau$  and other quantities, the explicit finite difference Equations (a) and (b) reduce to

$$\begin{aligned} T_1^{i+1} &= 0.0625T_1^i + 0.46875T_2^i + 33.482 \\ T_2^{i+1} &= 0.9375T_1^i + 0.032366T_2^i + 34.386 \end{aligned}$$

The initial temperature of the medium at  $t = 0$  and  $i = 0$  is given to be 200°C throughout, and thus  $T_1^0 = T_2^0 = 200^\circ\text{C}$ . Then the nodal temperatures at  $T_1^1$  and  $T_2^1$  at  $t = \Delta t = 15$  s are determined from these equations to be

$$\begin{aligned} T_1^1 &= 0.0625T_1^0 + 0.46875T_2^0 + 33.482 \\ &= 0.0625 \times 200 + 0.46875 \times 200 + 33.482 = 139.7^\circ\text{C} \\ T_2^1 &= 0.9375T_1^0 + 0.032366T_2^0 + 34.386 \\ &= 0.9375 \times 200 + 0.032366 \times 200 + 34.386 = 228.4^\circ\text{C} \end{aligned}$$

Similarly, the nodal temperatures  $T_1^2$  and  $T_2^2$  at  $t = 2\Delta t = 2 \times 15 = 30$  s are

$$\begin{aligned} T_1^2 &= 0.0625T_1^1 + 0.46875T_2^1 + 33.482 \\ &= 0.0625 \times 139.7 + 0.46875 \times 228.4 + 33.482 = 149.3^\circ\text{C} \\ T_2^2 &= 0.9375T_1^1 + 0.032366T_2^1 + 34.386 \\ &= 0.9375 \times 139.7 + 0.032366 \times 228.4 + 34.386 = 172.8^\circ\text{C} \end{aligned}$$

Continuing in the same manner, the temperatures at nodes 1 and 2 are determined for  $i = 1, 2, 3, 4, 5, \dots, 40$  and are given in Table 5–3. Therefore, the temperature at the exposed boundary surface 2.5 min after the start of cooling is

$$T_L^{2.5 \text{ min}} = T_2^{10} = 139.0^\circ\text{C}$$

(b) Node 1 is an interior node, and the *implicit* finite difference formulation at that node is obtained directly from Eq. 5–49 by setting  $m = 1$ :

$$\tau T_0 - (1 + 2\tau) T_1^{i+1} + \tau T_2^{i+1} + \tau \frac{\dot{e}_0 \Delta x^2}{k} + T_1^i = 0 \quad (c)$$

Node 2 is a boundary node subjected to convection, and the implicit finite difference formulation at that node can be obtained from this formulation by expressing the left side of the equation at time step  $i + 1$  instead of  $i$  as

$$\frac{2h\Delta x}{k} (T_\infty - T_2^{i+1}) + 2(T_1^{i+1} - T_2^{i+1}) + \frac{\dot{e}_2 \Delta x^2}{k} = \frac{T_2^{i+1} - T_2^i}{\tau}$$

TABLE 5–3

The variation of the nodal temperatures in Example 5–5 with time obtained by the *explicit* method

| Time Step, $i$ | Time, s | Node Temperature, °C |         |
|----------------|---------|----------------------|---------|
|                |         | $T_1^i$              | $T_2^i$ |
| 0              | 0       | 200.0                | 200.0   |
| 1              | 15      | 139.7                | 228.4   |
| 2              | 30      | 149.3                | 172.8   |
| 3              | 45      | 123.8                | 179.9   |
| 4              | 60      | 125.6                | 156.3   |
| 5              | 75      | 114.6                | 157.1   |
| 6              | 90      | 114.3                | 146.9   |
| 7              | 105     | 109.5                | 146.3   |
| 8              | 120     | 108.9                | 141.8   |
| 9              | 135     | 106.7                | 141.1   |
| 10             | 150     | 106.3                | 139.0   |
| 20             | 300     | 103.8                | 136.1   |
| 30             | 450     | 103.7                | 136.0   |
| 40             | 600     | 103.7                | 136.0   |

which can be rearranged as

$$2\tau T_1^{i+1} - \left(1 + 2\tau + 2\tau \frac{h\Delta x}{k}\right) T_2^{i+1} + 2\tau \frac{h\Delta x}{k} T_\infty + \tau \frac{\dot{e}_2 \Delta x^2}{k} + T_2^i = 0 \quad (d)$$

Again we did not use the superscript  $i$  or  $i + 1$  for quantities that do not change with time. The implicit method imposes no limit on the time step, and thus we can choose any value we want. However, we again choose  $\Delta t = 15$  s, and thus  $\tau = 0.46875$ , to make a comparison with part (a) possible. Substituting this value of  $\tau$  and other given quantities, the two implicit finite difference equations developed here reduce to

$$\begin{aligned} -1.9375T_1^{i+1} + 0.46875T_2^{i+1} + T_1^i + 33.482 &= 0 \\ 0.9375T_1^{i+1} - 1.9676T_2^{i+1} + T_2^i + 34.386 &= 0 \end{aligned}$$

Again  $T_1^0 = T_2^0 = 200^\circ\text{C}$  at  $t = 0$  and  $i = 0$  because of the initial condition, and for  $i = 0$ , these two equations reduce to

$$\begin{aligned} -1.9375T_1^1 + 0.46875T_2^1 + 200 + 33.482 &= 0 \\ 0.9375T_1^1 - 1.9676T_2^1 + 200 + 34.386 &= 0 \end{aligned}$$

The unknown nodal temperatures  $T_1^1$  and  $T_2^1$  at  $t = \Delta t = 15$  s are determined by solving these two equations simultaneously to be

$$T_1^1 = 168.8^\circ\text{C} \quad \text{and} \quad T_2^1 = 199.6^\circ\text{C}$$

Similarly, for  $i = 1$ , these equations reduce to

$$\begin{aligned} -1.9375T_2^1 + 0.46875T_2^2 + 168.8 + 33.482 &= 0 \\ 0.9375T_1^2 - 1.9676T_2^2 + 199.6 + 34.386 &= 0 \end{aligned}$$

The unknown nodal temperatures  $T_1^2$  and  $T_2^2$  at  $t = \Delta t = 2 \times 15 = 30$  s are determined by solving these two equations simultaneously to be

$$T_1^2 = 150.5^\circ\text{C} \quad \text{and} \quad T_2^2 = 190.6^\circ\text{C}$$

Continuing in this manner, the temperatures at nodes 1 and 2 are determined for  $i = 2, 3, 4, 5, \dots, 40$  and are listed in Table 5–4, and the temperature at the exposed boundary surface (node 2) 2.5 min after the start of cooling is obtained to be

$$T_L^{2.5 \text{ min}} = T_2^{10} = 143.9^\circ\text{C}$$

which is close to the result obtained by the explicit method. Note that either method could be used to obtain satisfactory results to transient problems, except, perhaps, for the first few time steps. The implicit method is preferred when it is desirable to use large time steps, and the explicit method is preferred when one wishes to avoid the simultaneous solution of a system of algebraic equations.

**TABLE 5–4**

The variation of the nodal temperatures in Example 5–5 with time obtained by the *implicit* method

| Time Step, $i$ | Time, s | Node Temperature, $^\circ\text{C}$ |         |
|----------------|---------|------------------------------------|---------|
|                |         | $T_1^i$                            | $T_2^i$ |
| 0              | 0       | 200.0                              | 200.0   |
| 1              | 15      | 168.8                              | 199.6   |
| 2              | 30      | 150.5                              | 190.6   |
| 3              | 45      | 138.6                              | 180.4   |
| 4              | 60      | 130.3                              | 171.2   |
| 5              | 75      | 124.1                              | 163.6   |
| 6              | 90      | 119.5                              | 157.6   |

| 8              | 120     | 113.2                              | 149.0   |
| 9              | 135     | 111.0                              | 146.1   |
| 10             | 150     | 109.4                              | 143.9   |
| 20             | 300     | 104.2                              | 136.7   |
| 30             | 450     | 103.8                              | 136.1   |
| 40             | 600     | 103.8                              | 136.1   |

**EXAMPLE 5–6** Solar Energy Storage in Trombe Walls

Dark painted thick masonry walls called Trombe walls are commonly used on south sides of passive solar homes to absorb solar energy, store it during the day, and release it to the house during the night (Fig. 5–46). The idea was proposed by E. L. Morse of Massachusetts in 1881 and is named after Professor Felix Trombe of France, who used it extensively in his designs in the 1970s. Usually a single or double layer of glazing is placed outside the wall and transmits most of the solar energy while blocking heat losses from the exposed surface of the wall to the outside. Also, air vents are commonly installed at the bottom and top of the Trombe walls so that the house air enters the parallel flow channel between the Trombe wall and the glazing, rises as it is heated, and enters the room through the top vent.

Consider a house in Reno, Nevada, whose south wall consists of a 1-ft-thick Trombe wall whose thermal conductivity is  $k = 0.40 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and whose thermal diffusivity is  $\alpha = 4.78 \times 10^{-6} \text{ ft}^2/\text{s}$ . The variation of the ambient temperature  $T_{\text{out}}$  and the solar heat flux  $\dot{q}_{\text{solar}}$  incident on a south-facing vertical surface throughout the day for a typical day in January is given in Table 5–5 in 3-h intervals. The Trombe wall has single glazing with an absorptivity-transmissivity product of  $\kappa = 0.77$  (that is, 77 percent of the solar energy incident is absorbed by the exposed surface of the Trombe wall), and the average combined heat transfer coefficient for heat loss from the Trombe wall to the ambient is determined to be  $h_{\text{out}} = 0.7 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ . The interior of the house is maintained at  $T_{\text{in}} = 70^\circ\text{F}$  at all times, and the heat transfer coefficient at the interior surface of the Trombe wall is  $h_{\text{in}} = 1.8 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ . Also, the vents on the Trombe wall are kept closed, and thus the only heat transfer between the air in the house and the Trombe wall is through the interior surface of the wall. Assuming the temperature of the Trombe wall to vary linearly between  $70^\circ\text{F}$  at the interior surface and  $30^\circ\text{F}$  at the exterior surface at 7 AM and using the explicit finite difference method with a uniform nodal spacing of  $\Delta x = 0.2 \text{ ft}$ , determine the temperature distribution along the thickness of the Trombe wall after 12, 24, 36, and 48 h. Also, determine the net amount of heat transferred to the house from the Trombe wall during the first day and the second day. Assume the wall is 10 ft high and 25 ft long.

**SOLUTION** The passive solar heating of a house through a Trombe wall is considered. The temperature distribution in the wall in 12-h intervals and the amount of heat transfer during the first and second days are to be determined.

**Assumptions** 1 Heat transfer is one-dimensional since the exposed surface of the wall is large relative to its thickness. 2 Thermal conductivity is constant. 3 The heat transfer coefficients are constant.

**Properties** The wall properties are given to be  $k = 0.40 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ,  $\alpha = 4.78 \times 10^{-6} \text{ ft}^2/\text{s}$ , and  $\kappa = 0.77$ .

**Analysis** The nodal spacing is given to be  $\Delta x = 0.2 \text{ ft}$ , and thus the total number of nodes along the Trombe wall is

$$M = \frac{L}{\Delta x} + 1 = \frac{1 \text{ ft}}{0.2 \text{ ft}} + 1 = 6$$

We number the nodes as 0, 1, 2, 3, 4, and 5, with node 0 on the interior surface of the Trombe wall and node 5 on the exterior surface, as shown in Figure 5–47. Nodes 1 through 4 are interior nodes, and the explicit finite difference formulations of these nodes are obtained directly from Eq. 5–47 to be

**FIGURE 5–46**

Schematic of a Trombe wall (Example 5–6).

**TABLE 5–5**

The hourly variation of monthly average ambient temperature and solar heat flux incident on a vertical surface for January in Reno, Nevada

| Time of Day | Ambient Temperature, °F | Solar Radiation, Btu/h·ft² |
|-------------|-------------------------|----------------------------|
| 7 AM–10 AM  | 33                      | 114                        |
| 10 AM–1 PM  | 43                      | 242                        |
| 1 PM–4 PM   | 45                      | 178                        |
| 4 PM–7 PM   | 37                      | 0                          |
| 7 PM–10 PM  | 32                      | 0                          |
| 10 PM–1 AM  | 27                      | 0                          |
| 1 AM–4 AM   | 26                      | 0                          |
| 4 AM–7 AM   | 25                      | 0                          |

FIGURE 5-47

The nodal network for the Trombe wall discussed in Example 5–6.

$$\text{Node 1 } (m = 1): \quad T_1^{i+1} = \tau(T_0^i + T_2^i) + (1 - 2\tau)T_1^i \quad (1)$$

$$\text{Node 2 } (m = 2): \quad T_2^{i+1} = \tau(T_1^i + T_3^i) + (1 - 2\tau)T_2^i \quad (2)$$

$$\text{Node 3 } (m = 3): \quad T_3^{i+1} = \tau(T_2^i + T_4^i) + (1 - 2\tau)T_3^i \quad (3)$$

$$\text{Node 4 } (m = 4): \quad T_4^{i+1} = \tau(T_3^i + T_5^i) + (1 - 2\tau)T_4^i \quad (4)$$

The interior surface is subjected to convection, and thus the explicit formulation of node 0 can be obtained directly from Eq. 5–51 to be

$$T_0^{i+1} = \left(1 - 2\tau - 2\tau \frac{h_{in} \Delta x}{k}\right) T_0^i + 2\tau T_1^i + 2\tau \frac{h_{in} \Delta x}{k} T_{in}$$

Substituting the quantities  $h_{in}$ ,  $\Delta x$ ,  $k$ , and  $T_{in}$ , which do not change with time, into this equation gives

$$T_0^{i+1} = (1 - 3.80\tau) T_0^i + \tau(2T_1^i + 126.0) \quad (5)$$

The exterior surface of the Trombe wall is subjected to convection as well as to heat flux. The explicit finite difference formulation at that boundary is obtained by writing an energy balance on the volume element represented by node 5,

$$h_{out} A(T_{out}^i - T_5^i) + \kappa A \dot{q}_{solar}^i + kA \frac{T_4^i - T_5^i}{\Delta x} = \rho A \frac{\Delta x}{2} c_p \frac{T_5^{i+1} - T_5^i}{\Delta t} \quad (5-53)$$

which simplifies to

$$T_5^{i+1} = \left(1 - 2\tau - 2\tau \frac{h_{out} \Delta x}{k}\right) T_5^i + 2\tau T_4^i + 2\tau \frac{h_{out} \Delta x}{k} T_{out}^i + 2\tau \frac{\kappa \dot{q}_{solar}^i \Delta x}{k} \quad (5-54)$$

where  $\tau = \alpha \Delta t / \Delta x^2$  is the dimensionless mesh Fourier number. Note that we kept the superscript  $i$  for quantities that vary with time. Substituting the quantities  $h_{out}$ ,  $\Delta x$ ,  $k$ , and  $\kappa$ , which do not change with time, into this equation gives

$$T_5^{i+1} = (1 - 2.70\tau) T_5^i + \tau(2T_4^i + 0.70T_{out}^i + 0.770\dot{q}_{solar}^i) \quad (6)$$

where the unit of  $\dot{q}_{solar}^i$  is Btu/h·ft².

Next we need to determine the upper limit of the time step  $\Delta t$  from the stability criterion since we are using the explicit method. This requires the identification of the smallest primary coefficient in the system. We know that the boundary nodes are more restrictive than the interior nodes, and thus we examine the formulations of the boundary nodes 0 and 5 only. The smallest and thus the most restrictive primary coefficient in this case is the coefficient of  $T_0^i$  in the formulation of node 0 since  $1 - 3.80\tau < 1 - 2.70\tau$ , and thus the stability criterion for this problem can be expressed as

$$1 - 3.80\tau \geq 0 \rightarrow \tau = \frac{\alpha \Delta x}{\Delta x^2} \leq \frac{1}{3.80}$$

Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\Delta t \leq \frac{\Delta x^2}{3.80\alpha} = \frac{(0.2 \text{ ft})^2}{3.80 \times (4.78 \times 10^{-6} \text{ ft}^2/\text{s})} = 2202 \text{ s}$$

Therefore, any time step less than 2202 s can be used to solve this problem. For convenience, let us choose the time step to be  $\Delta t = 900$  s = 15 min. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha \Delta t}{\Delta x^2} = \frac{(4.78 \times 10^{-6} \text{ ft}^2/\text{s})(900 \text{ s})}{(0.2 \text{ ft})^2} = 0.10755 \quad (\text{for } \Delta t = 15 \text{ min})$$

Initially (at 7 AM or  $t = 0$ ), the temperature of the wall is said to vary linearly between 70°F at node 0 and 30°F at node 5. Noting that there are five nodal spacings of equal length, the temperature change between two neighboring nodes is  $(70 - 30)/5 = 8^\circ\text{F}$ . Therefore, the initial nodal temperatures are

$$\begin{aligned} T_0^0 &= 70^\circ\text{F}, & T_1^0 &= 62^\circ\text{F}, & T_2^0 &= 54^\circ\text{F}, \\ T_3^0 &= 46^\circ\text{F}, & T_4^0 &= 38^\circ\text{F}, & T_5^0 &= 30^\circ\text{F} \end{aligned}$$

Then the nodal temperatures at  $t = \Delta t = 15$  min (at 7:15 AM) are determined from these equations to be

$$\begin{aligned} T_0^1 &= (1 - 3.80\tau) T_0^0 + \tau(2T_1^0 + 126.0) \\ &= (1 - 3.80 \times 0.10755) 70 + 0.10755(2 \times 62 + 126.0) = 68.3^\circ\text{F} \\ T_1^1 &= \tau(T_0^0 + T_2^0) + (1 - 2\tau) T_1^0 \\ &= 0.10755(70 + 54) + (1 - 2 \times 0.10755)62 = 62^\circ\text{F} \\ T_2^1 &= \tau(T_1^0 + T_3^0) + (1 - 2\tau) T_2^0 \\ &= 0.10755(62 + 46) + (1 - 2 \times 0.10755)54 = 54^\circ\text{F} \\ T_3^1 &= \tau(T_2^0 + T_4^0) + (1 - 2\tau) T_3^0 \\ &= 0.10755(54 + 38) + (1 - 2 \times 0.10755)46 = 46^\circ\text{F} \\ T_4^1 &= \tau(T_3^0 + T_5^0) + (1 - 2\tau) T_4^0 \\ &= 0.10755(46 + 30) + (1 - 2 \times 0.10755)38 = 38^\circ\text{F} \\ T_5^1 &= (1 - 2.70\tau) T_5^0 + \tau(2T_4^0 + 0.70T_{\text{out}}^0 + 0.770\dot{q}_{\text{solar}}^0) \\ &= (1 - 2.70 \times 0.10755)30 + 0.10755(2 \times 38 + 0.70 \times 33 + 0.770 \times 114) \\ &= 41.4^\circ\text{F} \end{aligned}$$

Note that the inner surface temperature of the Trombe wall dropped by  $1.7^\circ\text{F}$  and the outer surface temperature rose by  $11.4^\circ\text{F}$  during the first time step while the temperatures at the interior nodes remained the same. This is typical of transient problems in mediums that involve no heat generation. The nodal temperatures at the following time steps are determined similarly with the help of a computer. Note that the data for ambient temperature and the incident solar radiation change every 3 hours, which corresponds to 12 time steps, and this must be reflected in the computer program. For example, the value of  $\dot{q}_{\text{solar}}^i$  must be taken to be  $\dot{q}_{\text{solar}}^i = 114$  for  $i = 1-12$ ,  $\dot{q}_{\text{solar}}^i = 242$  for  $i = 13-24$ ,  $\dot{q}_{\text{solar}}^i = 178$  for  $i = 25-36$ , and  $\dot{q}_{\text{solar}}^i = 0$  for  $i = 37-96$ .

The results after 6, 12, 18, 24, 30, 36, 42, and 48 h are given in Table 5–6 and are plotted in Figure 5–48 for the first day. Note that the interior temperature of the Trombe wall drops in early morning hours, but then rises as the solar energy absorbed by the exterior surface diffuses through the wall. The exterior surface temperature of the Trombe wall rises from 30 to  $142^\circ\text{F}$  in just 6 h because of the solar energy absorbed, but then drops to  $53^\circ\text{F}$  by next morning as a result of heat loss at night. Therefore, it may be worthwhile to cover the outer surface at night to minimize the heat losses.

**FIGURE 5-48**  
The variation of temperatures in the Trombe wall discussed in Example 5–6.

TABLE 5-6

The temperatures at the nodes of a Trombe wall at various times

| Time        | Time Step, $i$ | Nodal Temperatures, °F |       |       |       |       |       |
|-------------|----------------|------------------------|-------|-------|-------|-------|-------|
|             |                | $T_0$                  | $T_1$ | $T_2$ | $T_3$ | $T_4$ | $T_5$ |
| 0 h (7 AM)  | 0              | 70.0                   | 62.0  | 54.0  | 46.0  | 38.0  | 30.0  |

The rate of heat transfer from the Trombe wall to the interior of the house during each time step is determined from Newton's law using the average temperature at the inner surface of the wall (node 0) as

$$Q_{\text{Trombe wall}}^i = \dot{Q}_{\text{Trombe wall}}^i \Delta t = h_{\text{in}} A (T_0^i - T_{\text{in}}) \Delta t = h_{\text{in}} A [(T_0^i + T_0^{i-1})/2 - T_{\text{in}}] \Delta t$$

Therefore, the amount of heat transfer during the first time step ( $i = 1$ ) or during the first 15-min period is

$$\begin{aligned} Q_{\text{Trombe wall}}^1 &= h_{\text{in}} A [(T_0^1 + T_0^0)/2 - T_{\text{in}}] \Delta t \\ &= (1.8 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^{\circ}\text{F})(10 \times 25 \text{ ft}^2)[(68.3 + 70)/2 - 70^{\circ}\text{F}](0.25 \text{ h}) \\ &= -95.6 \text{ Btu} \end{aligned}$$

The negative sign indicates that heat is transferred to the Trombe wall from the air in the house, which represents a heat loss. Then the total heat transfer during a specified time period is determined by adding the heat transfer amounts for each time step as

$$Q_{\text{Trombe wall}} = \sum_{i=1}^I Q_{\text{Trombe wall}}^i = \sum_{i=1}^I h_{\text{in}} A [(T_0^i + T_0^{i-1})/2 - T_{\text{in}}] \Delta t \quad (5-55)$$

where  $I$  is the total number of time intervals in the specified time period. In this case  $I = 48$  for 12 h, 96 for 24 h, and so on. Following the approach described here using a computer, the amount of heat transfer between the Trombe wall and the interior of the house is determined to be

$$Q_{\text{Trombe wall}} = -17,048 \text{ Btu after 12 h} \quad (17,048 \text{ Btu loss during the first 12 h})$$

$$Q_{\text{Trombe wall}} = -2483 \text{ Btu after 24 h} \quad (14,565 \text{ Btu gain during the second 12 h})$$

$$Q_{\text{Trombe wall}} = 5610 \text{ Btu after 36 h} \quad (8093 \text{ Btu gain during the third 12 h})$$

$$Q_{\text{Trombe wall}} = 34,400 \text{ Btu after 48 h} \quad (28,790 \text{ Btu gain during the fourth 12 h})$$

Therefore, the house loses 2483 Btu through the Trombe wall the first day as a result of the low start-up temperature but delivers a total of 36,883 Btu of heat to the house the second day. It can be shown that the Trombe wall will deliver even more heat to the house during the third day since it will start the day at a higher average temperature.

## Two-Dimensional Transient Heat Conduction

Consider a rectangular region in which heat conduction is significant in the  $x$ - and  $y$ -directions, and consider a unit depth of  $\Delta z = 1$  in the  $z$ -direction. Heat may be generated in the medium at a rate of  $\dot{e}(x, y, t)$ , which may vary with time and position, with the thermal conductivity  $k$  of the medium assumed to be constant. Now divide the  $x$ - $y$ -plane of the region into a *rectangular mesh* of nodal points spaced  $\Delta x$  and  $\Delta y$  apart in the  $x$ - and  $y$ -directions, respectively, and consider a general interior node  $(m, n)$  whose coordinates are  $x = m\Delta x$  and  $y = n\Delta y$ , as shown in Figure 5–49. Noting that the volume element centered about the general interior node  $(m, n)$  involves heat conduction from four sides (right, left, top, and bottom) and the volume of the element is  $V_{\text{element}} = \Delta x \times \Delta y \times 1 = \Delta x \Delta y$ , the transient finite difference formulation for a general interior node can be expressed on the basis of Eq. 5–39 as

$$\begin{aligned} k\Delta y \frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k\Delta x \frac{T_{m,n+1} - T_{m,n}}{\Delta y} + k\Delta y \frac{T_{m+1,n} - T_{m,n}}{\Delta x} \\ + k\Delta x \frac{T_{m,n-1} - T_{m,n}}{\Delta y} + \dot{e}_{m,n} \Delta x \Delta y = \rho \Delta x \Delta y c_p \frac{T_m^{i+1} - T_m^i}{\Delta t} \end{aligned} \quad (5-56)$$

Taking a square mesh ( $\Delta x = \Delta y = l$ ) and dividing each term by  $k$  gives after simplifying,

$$T_{m-1,n} + T_{m+1,n} + T_{m,n+1} + T_{m,n-1} - 4T_{m,n} + \frac{\dot{e}_{m,n} l^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau} \quad (5-57)$$

where again  $\alpha = k/\rho c_p$  is the thermal diffusivity of the material and  $\tau = \alpha \Delta t / l^2$  is the dimensionless mesh Fourier number. It can also be expressed in terms of the temperatures at the neighboring nodes in the following easy-to-remember form:

$$T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}} - 4T_{\text{node}} + \frac{\dot{e}_{\text{node}} l^2}{k} = \frac{T_{\text{node}}^{i+1} - T_{\text{node}}^i}{\tau} \quad (5-58)$$

Again the left side of this equation is simply the finite difference formulation of the problem for the *steady case*, as expected. Also, we are still not committed to explicit or implicit formulation since we did not indicate the time step on the left side of the equation. We now obtain the *explicit* finite difference formulation by expressing the left side at time step  $i$  as

$$T_{\text{left}}^i + T_{\text{top}}^i + T_{\text{right}}^i + T_{\text{bottom}}^i - 4T_{\text{node}}^i + \frac{\dot{e}_{\text{node}}^i l^2}{k} = \frac{T_{\text{node}}^{i+1} - T_{\text{node}}^i}{\tau} \quad (5-59)$$

Expressing the left side at time step  $i + 1$  instead of  $i$  would give the implicit formulation. Equation 5–59 can be solved *explicitly* for the new temperature  $T_{\text{node}}^{i+1}$  to give

$$T_{\text{node}}^{i+1} = \tau(T_{\text{left}}^i + T_{\text{top}}^i + T_{\text{right}}^i + T_{\text{bottom}}^i) + (1 - 4\tau) T_{\text{node}}^i + \tau \frac{\dot{e}_{\text{node}}^i l^2}{k} \quad (5-60)$$

for all interior nodes  $(m, n)$  where  $m = 1, 2, 3, \dots, M - 1$  and  $n = 1, 2, 3, \dots, N - 1$  in the medium. In the case of no heat generation and  $\tau = 1/4$  which is the upper limit of the stability criterion for the two-dimensional explicit method

**FIGURE 5-49**

The volume element of a general interior node  $(m, n)$  for two-dimensional transient conduction in rectangular coordinates.

Time step  $i$ :

Time step  $i + 1$ :

**FIGURE 5–50**

In the case of no heat generation and  $\tau = \frac{1}{4}$ , the temperature of an interior node at the new time step is the average of the temperatures of its neighboring nodes at the previous time step.

(see Eq. 5–61), the explicit finite difference formulation for a general interior node reduces to  $T_{\text{node}}^{i+1} = (T_{\text{left}}^i + T_{\text{top}}^i + T_{\text{right}}^i + T_{\text{bottom}}^i)/4$ , which has the interpretation that *the temperature of an interior node at the new time step is simply the average of the temperatures of its neighboring nodes at the previous time step* (Fig. 5–50).

The stability criterion that requires the coefficient of  $T_m^i$  in the  $T_m^{i+1}$  expression to be greater than or equal to zero for all nodes is equally valid for two- or three-dimensional cases and severely limits the size of the time step  $\Delta t$  that can be used with the explicit method. In the case of transient two-dimensional heat transfer in rectangular coordinates, the coefficient of  $T_m^i$  in the  $T_m^{i+1}$  expression is  $1 - 4\tau$ , and thus the stability criterion for all interior nodes in this case is  $1 - 4\tau > 0$ , or

$$\tau = \frac{\alpha \Delta t}{l^2} \leq \frac{1}{4} \quad (\text{interior nodes, two-dimensional heat transfer in rectangular coordinates}) \quad (5-61)$$

where  $\Delta x = \Delta y = l$ . When the material of the medium and thus its thermal diffusivity  $\alpha$  are known and the value of the mesh size  $l$  is specified, the largest allowable value of the time step  $\Delta t$  can be determined from the relation above. Again the boundary nodes involving convection and/or radiation are more restrictive than the interior nodes and thus require smaller time steps. Therefore, the most restrictive boundary node should be used in the determination of the maximum allowable time step  $\Delta t$  when a transient problem is solved with the explicit method.

The application of Eq. 5–60 to each of the  $(M - 1) \times (N - 1)$  interior nodes gives  $(M - 1) \times (N - 1)$  equations. The remaining equations are obtained by applying the method to the boundary nodes unless, of course, the boundary temperatures are specified as being constant. The development of the transient finite difference formulation of boundary nodes in two- (or three-) dimensional problems is similar to the development in the one-dimensional case discussed earlier. Again the region is partitioned between the nodes by forming volume elements around the nodes, and an energy balance is written for each boundary node on the basis of Eq. 5–39. This is illustrated in Example 5–7.

### EXAMPLE 5–7 Transient Two-Dimensional Heat Conduction in L-Bars

Consider two-dimensional transient heat transfer in an L-shaped solid body that is initially at a uniform temperature of 90°C and whose cross section is given in Fig. 5–51. The thermal conductivity and diffusivity of the body are  $k = 15 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.2 \times 10^{-6} \text{ m}^2/\text{s}$ , respectively, and heat is generated in the body at a rate of  $\dot{e} = 2 \times 10^6 \text{ W/m}^3$ . The left surface of the body is insulated, and the bottom surface is maintained at a uniform temperature of 90°C at all times. At time  $t = 0$ , the entire top surface is subjected to convection to ambient air at  $T_\infty = 25^\circ\text{C}$  with a convection coefficient of  $h = 80 \text{ W/m}^2\cdot\text{K}$ , and the right surface is subjected to heat flux at a uniform rate of  $\dot{q}_R = 5000 \text{ W/m}^2$ . The nodal network of the problem consists of 15 equally spaced nodes with  $\Delta x = \Delta y = 1.2 \text{ cm}$ , as shown in the figure. Five of the nodes are at the bottom surface, and thus their temperatures are known. Using the explicit method, determine the temperature at the top corner (node 3) of the body after 1, 3, 5, 10, and 60 min.

**FIGURE 5–51**

Schematic and nodal network for Example 5–7.

**SOLUTION** This is a transient two-dimensional heat transfer problem in rectangular coordinates, and it was solved in Example 5–3 for the steady case. Therefore, the solution of this transient problem should approach the solution for the steady case when the time is sufficiently large. The thermal conductivity and heat generation rate are given to be constants. We observe that all nodes are boundary nodes except node 5, which is an interior node. Therefore, we have to rely on energy balances to obtain the finite difference equations. The region is partitioned among the nodes equitably as shown in the figure, and the explicit finite difference equations are determined on the basis of the energy balance for the transient case expressed as

$$\sum_{\text{All sides}} \dot{Q}^i + \dot{e} V_{\text{element}} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

The quantities  $h$ ,  $T_\infty$ ,  $\dot{e}$ , and  $\dot{q}_R$  do not change with time, and thus we do not need to use the superscript  $i$  for them. Also, the energy balance expressions are simplified using the definitions of thermal diffusivity  $\alpha = k/\rho c_p$  and the dimensionless mesh Fourier number  $\tau = \alpha \Delta t / l^2$ , where  $\Delta x = \Delta y = l$ .

(a) Node 1. (Boundary node subjected to convection and insulation, Fig. 5–52a)

$$\begin{aligned} h \frac{\Delta x}{2} (T_\infty - T_1^i) + k \frac{\Delta y}{2} \frac{T_2^i - T_1^i}{\Delta x} + k \frac{\Delta x}{2} \frac{T_4^i - T_1^i}{\Delta y} \\ + \dot{e}_1 \frac{\Delta x}{2} \frac{\Delta y}{2} = \rho \frac{\Delta x}{2} \frac{\Delta y}{2} c_p \frac{T_1^{i+1} - T_1^i}{\Delta t} \end{aligned}$$

Dividing by  $k/4$  and simplifying,

$$\frac{2hl}{k} (T_\infty - T_1^i) + 2(T_2^i - T_1^i) + 2(T_4^i - T_1^i) + \frac{\dot{e}_1 l^2}{k} = \frac{T_1^{i+1} - T_1^i}{\tau}$$

which can be solved for  $T_1^{i+1}$  to give

$$T_1^{i+1} = \left( 1 - 4\tau - 2\tau \frac{hl}{k} \right) T_1^i + 2\tau \left( T_2^i + T_4^i + \frac{hl}{k} T_\infty + \frac{\dot{e}_1 l^2}{2k} \right)$$

(b) Node 2. (Boundary node subjected to convection, Fig. 5–52b)

$$\begin{aligned} h \Delta x (T_\infty - T_2^i) + k \frac{\Delta y}{2} \frac{T_3^i - T_2^i}{\Delta x} + k \Delta x \frac{T_5^i - T_2^i}{\Delta y} \\ + k \frac{\Delta y}{2} \frac{T_1^i - T_2^i}{\Delta x} + \dot{e}_2 \Delta x \frac{\Delta y}{2} = \rho \Delta x \frac{\Delta y}{2} c_p \frac{T_2^{i+1} - T_2^i}{\Delta t} \end{aligned}$$

Dividing by  $k/2$ , simplifying, and solving for  $T_2^{i+1}$  gives

$$T_2^{i+1} = \left( 1 - 4\tau - 2\tau \frac{hl}{k} \right) T_2^i + \tau \left( T_1^i + T_3^i + 2T_5^i + \frac{2hl}{k} T_\infty + \frac{\dot{e}_2 l^2}{k} \right)$$

**FIGURE 5-52**

**FIGURE 5-55**

Schematics for energy balances on the volume elements of nodes 7 and 9.

(c) Node 3. (Boundary node subjected to convection on two sides, Fig. 5-53a)

$$h\left(\frac{\Delta x}{2} + \frac{\Delta y}{2}\right)(T_\infty - T_3^i) + k \frac{\Delta x}{2} \frac{T_6^i - T_3^i}{\Delta y} + k \frac{\Delta y}{2} \frac{T_2^i - T_3^i}{\Delta x} + \dot{e}_3 \frac{\Delta x}{2} \frac{\Delta y}{2} = \rho \frac{\Delta x}{2} \frac{\Delta y}{2} c_p \frac{T_3^{i+1} - T_3^i}{\Delta t}$$

Dividing by  $k/4$ , simplifying, and solving for  $T_3^{i+1}$  gives

$$T_3^{i+1} = \left(1 - 4\tau - 4\tau \frac{hl}{k}\right) T_3^i + 2\tau \left(T_2^i + T_6^i + 2 \frac{hl}{k} T_\infty + \frac{\dot{e}_3 l^2}{2k}\right)$$

(d) Node 4. (On the insulated boundary, and can be treated as an interior node, Fig. 5-53b). Noting that  $T_{10} = 90^\circ\text{C}$ , Eq. 5-60 gives

$$T_4^{i+1} = (1 - 4\tau) T_4^i + \tau \left(T_1^i + 2T_5^i + 90 + \frac{\dot{e}_4 l^2}{k}\right)$$

(e) Node 5. (Interior node, Fig. 5-54a). Noting that  $T_{11} = 90^\circ\text{C}$ , Eq. 5-60 gives

$$T_5^{i+1} = (1 - 4\tau) T_5^i + \tau \left(T_2^i + T_4^i + T_6^i + 90 + \frac{\dot{e}_5 l^2}{k}\right)$$

(f) Node 6. (Boundary node subjected to convection on two sides, Fig. 5-54b)

$$h\left(\frac{\Delta x}{2} + \frac{\Delta y}{2}\right)(T_\infty - T_6^i) + k \frac{\Delta y}{2} \frac{T_7^i - T_6^i}{\Delta x} + k \Delta x \frac{T_{12}^i - T_6^i}{\Delta y} + k \Delta y \frac{T_5^i - T_6^i}{\Delta x} + \frac{\Delta x}{2} \frac{T_3^i - T_6^i}{\Delta y} + \dot{e}_6 \frac{3\Delta x \Delta y}{4} = \rho \frac{3\Delta x \Delta y}{4} c_p \frac{T_6^{i+1} - T_6^i}{\Delta t}$$

Dividing by  $3k/4$ , simplifying, and solving for  $T_6^{i+1}$  gives

$$T_6^{i+1} = \left(1 - 4\tau - 4\tau \frac{hl}{3k}\right) T_6^i + \frac{\tau}{3} \left[2T_3^i + 4T_5^i + 2T_7^i + 4 \times 90 + 4 \frac{hl}{k} T_\infty + 3 \frac{\dot{e}_6 l^2}{k}\right]$$

(g) Node 7. (Boundary node subjected to convection, Fig. 5-55a)

$$h \Delta x (T_\infty - T_7^i) + k \frac{\Delta y}{2} \frac{T_8^i - T_7^i}{\Delta x} + k \Delta x \frac{T_{13}^i - T_7^i}{\Delta y} + k \frac{\Delta y}{2} \frac{T_6^i - T_7^i}{\Delta x} + \dot{e}_7 \Delta x \frac{\Delta y}{2} = \rho \Delta x \frac{\Delta y}{2} c_p \frac{T_7^{i+1} - T_7^i}{\Delta t}$$

Dividing by  $k/2$ , simplifying, and solving for  $T_7^{i+1}$  gives

$$T_7^{i+1} = \left(1 - 4\tau - 2\tau \frac{hl}{k}\right) T_7^i + \tau \left[T_6^i + T_8^i + 2 \times 90 + \frac{2hl}{k} T_\infty + \frac{\dot{e}_7 l^2}{k}\right]$$

(h) Node 8. This node is identical to node 7, and the finite difference formulation of this node can be obtained from that of node 7 by shifting the node numbers by 1 (i.e., replacing subscript  $m$  by subscript  $m + 1$ ). It gives

$$T_8^{i+1} = \left(1 - 4\tau - 2\tau \frac{hl}{k}\right) T_8^i + \tau \left[ T_7^i + T_9^i + 2 \times 90 + \frac{2hl}{k} T_\infty + \frac{\dot{e}_8 l^2}{k} \right]$$

(i) Node 9. (Boundary node subjected to convection on two sides, Fig. 5–55b)

$$\begin{aligned} h \frac{\Delta x}{2} (T_\infty - T_9^i) + \dot{q}_R \frac{\Delta y}{2} + k \frac{\Delta x}{2} \frac{T_{15}^i - T_9^i}{\Delta y} \\ + \frac{k \Delta y}{2} \frac{T_8^i - T_9^i}{\Delta x} + \dot{e}_9 \frac{\Delta x}{2} \frac{\Delta y}{2} = \rho \frac{\Delta x}{2} \frac{\Delta y}{2} c_p \frac{T_9^{i+1} - T_9^i}{\Delta t} \end{aligned}$$

Dividing by  $k/4$ , simplifying, and solving for  $T_9^{i+1}$  gives

$$T_9^{i+1} = \left(1 - 4\tau - 2\tau \frac{hl}{k}\right) T_9^i + 2\tau \left( T_8^i + 90 + \frac{\dot{q}_R l}{k} + \frac{hl}{k} T_\infty + \frac{\dot{e}_9 l^2}{2k} \right)$$

This completes the finite difference formulation of the problem. Next we need to determine the upper limit of the time step  $\Delta t$  from the stability criterion, which requires the coefficient of  $T_m^i$  in the  $T_m^{i+1}$  expression (the primary coefficient) to be greater than or equal to zero for all nodes. The smallest primary coefficient in the nine equations here is the coefficient of  $T_3^i$  in the  $T_3^{i+1}$  expression, and thus the stability criterion for this problem can be expressed as

$$1 - 4\tau - 4\tau \frac{hl}{k} \geq 0 \quad \rightarrow \quad \tau \leq \frac{1}{4(1 + hl/k)} \quad \rightarrow \quad \Delta t \leq \frac{l^2}{4\alpha(1 + hl/k)}$$

since  $\tau = \alpha \Delta t / l^2$ . Substituting the given quantities, the maximum allowable value of the time step is determined to be

$$\Delta t \leq \frac{(0.012 \text{ m})^2}{4(3.2 \times 10^{-6} \text{ m}^2/\text{s})[1 + (80 \text{ W/m}^2 \cdot \text{K})(0.012 \text{ m})/(15 \text{ W/m} \cdot \text{K})]} = 10.6 \text{ s}$$

Therefore, any time step less than 10.6 s can be used to solve this problem. For convenience, let us choose the time step to be  $\Delta t = 10$  s. Then the mesh Fourier number becomes

$$\tau = \frac{\alpha \Delta t}{l^2} = \frac{(3.2 \times 10^{-6} \text{ m}^2/\text{s})(10 \text{ s})}{(0.012 \text{ m})^2} = 0.222 \quad (\text{for } \Delta t = 10 \text{ s})$$

Substituting this value of  $\tau$  and other given quantities, the developed transient finite difference equations simplify to

$$\begin{aligned} T_1^{i+1} &= 0.0836T_1^i + 0.444(T_2^i + T_4^i + 11.2) \\ T_2^{i+1} &= 0.0836T_2^i + 0.222(T_1^i + T_3^i + 2T_5^i + 22.4) \\ T_3^{i+1} &= 0.0552T_3^i + 0.444(T_2^i + T_6^i + 12.8) \\ T_4^{i+1} &= 0.112T_4^i + 0.222(T_1^i + 2T_5^i + 109.2) \\ T_5^{i+1} &= 0.112T_5^i + 0.222(T_2^i + T_4^i + T_6^i + 109.2) \\ T_6^{i+1} &= 0.0931T_6^i + 0.074(2T_3^i + 4T_5^i + 2T_7^i + 424) \end{aligned}$$

$$T_7^{i+1} = 0.0836T_7^i + 0.222(T_6^i + T_8^i + 202.4)$$

$$T_8^{i+1} = 0.0836T_8^i + 0.222(T_7^i + T_9^i + 202.4)$$

$$T_9^{i+1} = 0.0836T_9^i + 0.444(T_8^i + 105.2)$$

Using the specified initial condition as the solution at time  $t = 0$  (for  $i = 0$ ), sweeping through these nine equations gives the solution at intervals of 10 s. The solution at the upper corner node (node 3) is determined to be 100.2, 105.9, 106.5, 106.6, and 106.6°C at 1, 3, 5, 10, and 60 min, respectively. Note that the last three solutions are practically identical to the solution for the steady case obtained in Example 5–3. This indicates that steady conditions are reached in the medium after about 5 min.

## TOPIC OF SPECIAL INTEREST\*

### Controlling the Numerical Error

A comparison of the numerical results with the exact results for temperature distribution in a cylinder would show that the results obtained by a numerical method are approximate, and they may or may not be sufficiently close to the exact (true) solution values. The difference between a numerical solution and the exact solution is the **error** involved in the numerical solution, and it is primarily due to two sources:

- The **discretization error** (also called the *truncation* or *formulation* error), which is caused by the approximations used in the formulation of the numerical method.
- The **round-off error**, which is caused by the computer's use of a limited number of significant digits and continuously rounding (or chopping) off the digits it cannot retain.

Below we discuss both types of errors.

### Discretization Error

The discretization error involved in numerical methods is due to replacing the *derivatives* by *differences* in each step, or the actual temperature distribution between two adjacent nodes by a straight line segment.

Consider the variation of the solution of a transient heat transfer problem with time at a specified nodal point. Both the numerical and actual (exact) solutions coincide at the beginning of the first time step, as expected, but the numerical solution deviates from the exact solution as the time  $t$  increases. The difference between the two solutions at  $t = \Delta t$  is due to the approximation at the first time step only and is called the *local discretization error*. One would expect the situation to get worse with each step since the second step uses the erroneous result of the first step as its starting point and adds a second local discretization error on top of it, as shown in Fig. 5–56. The accumulation of the local discretization errors continues with the increasing number of time steps, and the total discretization error at any

**FIGURE 5–56**

The local and global discretization errors of the finite difference method at the third time step at a specified nodal point.

\*This section can be skipped without a loss of continuity.

step is called the *global* or *accumulated discretization error*. Note that the local and global discretization errors are identical for the first time step. The global discretization error usually increases with the increasing number of steps, but the opposite may occur when the solution function changes direction frequently, giving rise to local discretization errors of opposite signs, which tend to cancel each other.

To have an idea about the magnitude of the local discretization error, consider the Taylor series expansion of the temperature at a specified nodal point  $m$  about time  $t_i$ ,

$$T(x_m, t_i + \Delta t) = T(x_m, t_i) + \Delta t \frac{\partial T(x_m, t_i)}{\partial t} + \frac{1}{2} \Delta t^2 \frac{\partial^2 T(x_m, t_i)}{\partial t^2} + \dots \quad (5-62)$$

The finite difference formulation of the time derivative at the same nodal point is expressed as

$$\frac{\partial T(x_m, t_i)}{\partial t} \cong \frac{T(x_m, t_i + \Delta t) - T(x_m, t_i)}{\Delta t} = \frac{T_m^{i+1} - T_m^i}{\Delta t} \quad (5-63)$$

or

$$T(x_m, t_i + \Delta t) \cong T(x_m, t_i) + \Delta t \frac{\partial T(x_m, t_i)}{\partial t} \quad (5-64)$$

which resembles the *Taylor series expansion* terminated after the first two terms. Therefore, the third and later terms in the Taylor series expansion represent the error involved in the finite difference approximation. For a sufficiently small time step, these terms decay rapidly as the order of derivative increases, and their contributions become smaller and smaller. The first term neglected in the Taylor series expansion is proportional to  $\Delta t^2$ , and thus the local discretization error of this approximation, which is the error involved in each step, is also proportional to  $\Delta t^2$ .

The local discretization error is the formulation error associated with a single step and gives an idea about the accuracy of the method used. However, the solution results obtained at every step except the first one involve the *accumulated error* up to that point, and the local error alone does not have much significance. What we really need to know is the global discretization error. At the worst case, the accumulated discretization error after  $I$  time steps during a time period  $t_0$  is  $i(\Delta t)^2 = (t_0/\Delta t)(\Delta t)^2 = t_0\Delta t$ , which is proportional to  $\Delta t$ . Thus, we conclude that the local discretization error is proportional to the square of the step size  $\Delta t^2$  while the global discretization error is proportional to the step size  $\Delta t$  itself. Therefore, the smaller the mesh size (or the size of the time step in transient problems), the smaller the error, and thus the more accurate is the approximation. For example, halving the step size will reduce the global discretization error by half. It should be clear from the previous discussions that the discretization error can be minimized by decreasing the step size in space or time as much as possible. The discretization error approaches zero as the difference quantities such as  $\Delta x$  and  $\Delta t$  approach the differential quantities such as  $dx$  and  $dt$ .

## Round-Off Error

If we had a computer that could retain an infinite number of digits for all numbers, the difference between the exact solution and the approximate (numerical) solution at any point would entirely be due to discretization error.

**FIGURE 5-57**

A simple arithmetic operation performed with a computer in single precision using seven significant digits, which results in 30.8 percent error when the order of operation is reversed.

**FIGURE 5-58**

As the mesh or time step size decreases, the discretization error decreases but the round-off error increases.

But we know that every computer (or calculator) represents numbers using a finite number of significant digits. The default value of the number of significant digits for many computers is 7, which is referred to as *single precision*. But the user may perform the calculations using 15 significant digits for the numbers, if he or she wishes, which is referred to as *double precision*. Of course, performing calculations in double precision will require more computer memory and a longer execution time.

In single precision mode with seven significant digits, a computer registers the number 44444.666666 as 44444.67 or 44444.66, depending on the method of rounding the computer uses. In the first case, the excess digits are said to be *rounded* to the closest integer, whereas in the second case they are said to be *chopped off*. Therefore, the numbers  $a = 44444.12345$  and  $b = 44444.12032$  are equivalent for a computer that performs calculations using seven significant digits. Such a computer would give  $a - b = 0$  instead of the true value 0.00313.

The error due to retaining a limited number of digits during calculations is called the **round-off error**. This error is random in nature and there is no easy and systematic way of predicting it. It depends on the number of calculations, the method of rounding off, the type of computer, and even the sequence of calculations.

In algebra you learned that  $a + b + c = a + c + b$ , which seems quite reasonable. But this is not necessarily true for calculations performed with a computer, as demonstrated in Fig. 5-57. Note that changing the sequence of calculations results in an error of 30.8 percent in just two operations. Considering that any significant problem involves thousands or even millions of such operations performed in sequence, we realize that the accumulated round-off error has the potential to cause serious error without giving any warning signs. Experienced programmers are very much aware of this danger, and they structure their programs to prevent any buildup of the round-off error. For example, it is much safer to multiply a number by 10 than to add it 10 times. Also, it is much safer to start any addition process with the smallest numbers and continue with larger numbers. This rule is particularly important when evaluating series with a large number of terms with alternating signs.

The round-off error is proportional to the *number of computations* performed during the solution. In the finite difference method, the number of calculations increases as the mesh size or the time step size decreases. Halving the mesh or time step size, for example, doubles the number of calculations and thus the accumulated round-off error.

## Controlling the Error in Numerical Methods

The total error in any result obtained by a numerical method is the sum of the *discretization error*, which decreases with decreasing step size, and the *round-off error*, which increases with decreasing step size, as shown in Fig. 5-58. Therefore, decreasing the step size too much in order to get more accurate results may actually backfire and give less accurate results because of a faster increase in the round-off error. We should be careful not to let round-off error get out of control by avoiding a large number of computations with very small numbers.

In practice, we do not know the exact solution of the problem, and thus we cannot determine the magnitude of the error involved in the numerical method.

Knowing that the global discretization error is proportional to the step size is not much help either since there is no easy way of determining the value of the proportionality constant. Besides, the global discretization error alone is meaningless without a true estimate of the round-off error. Therefore, we recommend the following practical procedures to assess the accuracy of the results obtained by a numerical method.

- Start the calculations with a reasonable mesh size  $\Delta x$  (and time step size  $\Delta t$  for transient problems) based on experience. Then repeat the calculations using a mesh size of  $\Delta x/2$ . If the results obtained by halving the mesh size do not differ significantly from the results obtained with the full mesh size, we conclude that the discretization error is at an acceptable level. But if the difference is larger than we can accept, then we have to repeat the calculations using a mesh size  $\Delta x/4$  or even a smaller one at regions of high temperature gradients. We continue in this manner until halving the mesh size does not cause any significant change in the results, which indicates that the discretization error is reduced to an acceptable level.
- Repeat the calculations using double precision holding the mesh size (and the size of the time step in transient problems) constant. If the changes are not significant, we conclude that the round-off error is not a problem. But if the changes are too large to accept, then we may try reducing the total number of calculations by increasing the mesh size or changing the order of computations. But if the increased mesh size gives unacceptable discretization errors, then we may have to find a reasonable compromise.

It should always be kept in mind that the results obtained by any numerical method may not reflect any trouble spots in certain problems that require special consideration such as hot spots or areas of high temperature gradients. The results that seem quite reasonable overall may be in considerable error at certain locations. This is another reason for always repeating the calculations at least twice with different mesh sizes before accepting them as the solution of the problem. Most commercial software packages have built-in routines that vary the mesh size as necessary to obtain highly accurate solutions. But it is a good engineering practice to be aware of any potential pitfalls of numerical methods and to examine the results obtained with a critical eye.

## SUMMARY

Analytical solution methods are limited to highly simplified problems in simple geometries, and it is often necessary to use a numerical method to solve real world problems with complicated geometries or nonuniform thermal conditions. The numerical *finite difference method* is based on replacing derivatives by differences, and the finite difference formulation of a heat transfer problem is obtained by selecting a sufficient number of points in the region, called the *nodal points* or nodes, and writing *energy balances* on the volume elements centered about the nodes.

For *steady* heat transfer, the *energy balance* on a volume element can be expressed in general as

$$\sum_{\text{All sides}} \dot{Q} + \dot{e}V_{\text{element}} = 0$$

whether the problem is one-, two-, or three-dimensional. For convenience in formulation, we always assume all heat transfer to be *into* the volume element from all surfaces toward the node under consideration, except for specified heat flux whose direction is already specified. The finite difference

formulations for a general interior node under *steady* conditions are expressed for some geometries as follows:

*One-dimensional steady conduction in a plane wall:*

$$\frac{T_{m-1} - 2T_m + T_{m+1}}{(\Delta x)^2} + \frac{\dot{e}_m}{k} = 0$$

*Two-dimensional steady conduction in rectangular coordinates:*

$$T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}} - 4T_{\text{node}} + \frac{\dot{e}_{\text{node}}l^2}{k} = 0$$

where  $\Delta x$  is the nodal spacing for the plane wall and  $\Delta x = \Delta y = l$  is the nodal spacing for the two-dimensional case. Insulated boundaries can be viewed as mirrors in formulation, and thus the nodes on insulated boundaries can be treated as interior nodes by using mirror images.

The finite difference formulation at node 0 at the left boundary of a plane wall for steady one-dimensional heat conduction can be expressed as

$$\dot{Q}_{\text{left surface}} + kA \frac{T_1 - T_0}{\Delta x} + \dot{e}_0(A\Delta x/2) = 0$$

where  $A\Delta x/2$  is the volume of the volume,  $\dot{e}_0$  is the rate of heat generation per unit volume at  $x = 0$ , and  $A$  is the heat transfer area. The form of the first term depends on the boundary condition at  $x = 0$  (convection, radiation, specified heat flux, etc.).

The finite difference formulation of heat conduction problems usually results in a system of  $N$  algebraic equations in  $N$  unknown nodal temperatures that need to be solved simultaneously.

The finite difference formulation of *transient* heat conduction problems is based on an energy balance that also accounts for the variation of the energy content of the volume element during a time interval  $\Delta t$ . The heat transfer and heat generation terms are expressed at the previous time step  $i$  in the *explicit method*, and at the new time step  $i + 1$  in the *implicit method*. For a general node  $m$ , the finite difference formulations are expressed as

*Explicit method:*

$$\sum_{\text{All sides}} \dot{Q}^i + \dot{e}_m^i V_{\text{element}} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

*Implicit method:*

$$\sum_{\text{All sides}} \dot{Q}^{i+1} + \dot{e}_m^{i+1} V_{\text{element}} = \rho V_{\text{element}} c_p \frac{T_m^{i+1} - T_m^i}{\Delta t}$$

where  $T_m^i$  and  $T_m^{i+1}$  are the temperatures of node  $m$  at times  $t_i = i\Delta t$  and  $t_{i+1} = (i + 1)\Delta t$ , respectively, and  $T_m^{i+1} - T_m^i$  represents the temperature change of the node during the time interval  $\Delta t$  between the time steps  $i$  and  $i + 1$ . The explicit and implicit formulations given here are quite general and can be used in any coordinate system regardless of heat transfer being one-, two-, or three-dimensional.

The explicit formulation of a general interior node for one- and two-dimensional heat transfer in rectangular coordinates can be expressed as

*One-dimensional case:*

$$T_m^{i+1} = \tau(T_{m-1}^i + T_{m+1}^i) + (1 - 2\tau)T_m^i + \tau \frac{\dot{e}_m^i \Delta x^2}{k}$$

*Two-dimensional case:*

$$T_{\text{node}}^{i+1} = \tau(T_{\text{left}}^i + T_{\text{top}}^i + T_{\text{right}}^i + T_{\text{bottom}}^i) + (1 - 4\tau)T_{\text{node}}^i + \tau \frac{\dot{e}_{\text{node}}^i l^2}{k}$$

where  $\tau = \alpha \Delta t / \Delta x^2$  is the dimensionless *mesh Fourier number* and  $\alpha = k/\rho c_p$  is the *thermal diffusivity* of the medium.

The implicit method is inherently stable, and any value of  $\Delta t$  can be used with that method as the time step. The largest value of the time step  $\Delta t$  in the explicit method is limited by the *stability criterion*, expressed as: *the coefficients of all  $T_m^i$  in the  $T_m^{i+1}$  expressions (called the primary coefficients) must be greater than or equal to zero for all nodes  $m$ .* The maximum value of  $\Delta t$  is determined by applying the stability criterion to the equation with the smallest primary coefficient since it is the most restrictive. For problems with specified temperatures or heat fluxes at all the boundaries, the stability criterion can be expressed as  $\tau \leq \frac{1}{2}$  for one-dimensional problems and  $\tau \leq \frac{1}{4}$  for the two-dimensional problems in rectangular coordinates.

## PROBLEMS\*

### Why Numerical Methods?

**5–1C** With powerful computers and software packages readily available, do you think obtaining analytical solutions to engineering problems will eventually disappear from engineering curricula?

**5–2C** What are the limitations of the analytical solution methods?

**5–3C** Consider a heat conduction problem that can be solved both analytically, by solving the governing differential equation and applying the boundary conditions, and numerically, by a software package available on your computer. Which approach would you use to solve this problem? Explain your reasoning.

**5–4C** What is the basis of the energy balance method? How does it differ from the formal finite difference method? For a specified nodal network, will these two methods result in the same or a different set of equations?

**5–5C** How do numerical solution methods differ from analytical ones? What are the advantages and disadvantages of numerical and analytical methods?

**5–6C** Two engineers are to solve an actual heat transfer problem in a manufacturing facility. Engineer A makes the necessary simplifying assumptions and solves the problem analytically, while engineer B solves it numerically using a powerful software package. Engineer A claims he solved the problem exactly and thus his results are better, while engineer B claims that he used a more realistic model and thus his results are better. To resolve the dispute, you are asked to solve the problem experimentally in a lab. Which engineer do you think the experiments will prove right? Explain.

### Finite Difference Formulation of Differential Equations

**5–7C** Define these terms used in the finite difference formulation: node, nodal network, volume element, nodal spacing, and difference equation.

---

\*Problems designated by a “C” are concept questions, and students are encouraged to answer them all. Problems designated by an “E” are in English units, and the SI users can ignore them. Problems with the icon  are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon  are comprehensive in nature, and are intended to be solved with an equation solver such as EES.

**5–8** The finite difference formulation of steady two-dimensional heat conduction in a medium with heat generation and constant thermal conductivity is given by

$$\frac{T_{m-1,n} - 2T_{m,n} + T_{m+1,n}}{\Delta x^2} + \frac{T_{m,n-1} - 2T_{m,n} + T_{m,n+1}}{\Delta y^2} + \frac{\dot{e}_{m,n}}{k} = 0$$

in rectangular coordinates. Modify this relation for the three-dimensional case.

**5–9** For a one dimensional steady state variable thermal conductivity heat conduction with uniform internal heat generation, develop a generalized finite difference formulation for the interior nodes, with left surface boundary node exposed to constant heat flux and right surface boundary node exposed to convective environment. The variable conductivity is modeled such that the thermal conductivity varies linearly with the temperature as  $k(T) = k_o(1 + \beta T)$  where  $T$  is the average temperature between the two nodes.

**5–10** In many engineering applications variation in thermal properties is significant especially when there are large temperature gradients or the material is not homogeneous. To account for these variations in thermal properties, develop a finite difference formulation for an internal node in case of a three dimensional steady state heat conduction equation with variable thermal conductivity.

**5–11** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, and 4 with a uniform nodal spacing of  $\Delta x$ . Using the finite difference form of the first derivative (*not* the energy balance approach), obtain the finite difference formulation of the boundary nodes for the case of uniform heat flux  $q_0$  at the left boundary (node 0) and convection at the right boundary (node 4) with a convection coefficient of  $h$  and an ambient temperature of  $T_\infty$ .

**5–12** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and constant thermal conductivity, as shown in Fig. P5–12 on the next page. The nodal network of the medium consists of nodes 0, 1, 2, 3, 4, and 5 with a uniform nodal spacing of  $\Delta x$ . Using the finite difference form of the first derivative (*not* the energy balance approach), obtain the finite difference formulation of the

boundary nodes for the case of insulation at the left boundary (node 0) and radiation at the right boundary (node 5) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{surr}}$ .

FIGURE P5-12

### One-Dimensional Steady Heat Conduction

**5-13C** Explain how the finite difference form of a heat conduction problem is obtained by the energy balance method.

**5-14C** What are the basic steps involved in solving a system of equations with Gauss-Seidel method?

**5-15C** Consider a medium in which the finite difference formulation of a general interior node is given in its simplest form as

$$\frac{T_{m-1} - 2T_m + T_{m+1}}{\Delta x^2} + \frac{\dot{e}_m}{k} = 0$$

- (a) Is heat transfer in this medium steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the nodal spacing constant or variable?
- (e) Is the thermal conductivity of the medium constant or variable?

**5-16C** How is an insulated boundary handled in finite difference formulation of a problem? How does a symmetry line differ from an insulated boundary in the finite difference formulation?

**5-17C** How can a node on an insulated boundary be treated as an interior node in the finite difference formulation of a plane wall? Explain.

**5-18C** In the energy balance formulation of the finite difference method, it is recommended that all heat transfer at the boundaries of the volume element be assumed to be into the volume element even for steady heat conduction. Is this a valid recommendation even though it seems to violate the conservation of energy principle?

**5-19** Consider steady heat conduction in a plane wall whose left surface (node 0) is maintained at 30°C while the right surface (node 8) is subjected to a heat flux of 1200 W/m<sup>2</sup>. Express the finite difference formulation of the boundary nodes 0 and 8 for the case of no heat generation. Also obtain the finite

difference formulation for the rate of heat transfer at the left boundary.

FIGURE P5-19

**5-20** Consider steady heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, and 4 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of the boundary nodes for the case of uniform heat flux  $\dot{q}_0$  at the left boundary (node 0) and convection at the right boundary (node 4) with a convection coefficient of  $h$  and an ambient temperature of  $T_{\infty}$ .

**5-21** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, 4, and 5 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of the boundary nodes for the case of insulation at the left boundary (node 0) and radiation at the right boundary (node 5) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{surr}}$ .

**5-22** Consider steady one-dimensional heat conduction in a composite plane wall consisting of two layers A and B in perfect contact at the interface. The wall involves no heat generation. The nodal network of the medium consists of nodes 0, 1 (at the interface), and 2 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of this problem for the case of insulation at the left boundary (node 0) and radiation at the right boundary (node 2) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{surr}}$ .

**5-23** Consider steady one-dimensional heat conduction in a pin fin of constant diameter  $D$  with constant thermal conductivity. The fin is losing heat by convection to the ambient air at  $T_{\infty}$  with a convection coefficient of  $h$ , and by radiation to the surrounding surfaces at an average temperature of  $T_{\text{surr}}$ . The nodal network of the fin consists of nodes 0 (at the base), 1 (in the middle), and 2 (at the fin tip) with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of this problem to determine  $T_1$  and  $T_2$  for the case of specified temperature at the fin base and negligible heat transfer at the fin tip. All temperatures are in °C.

FIGURE P5-23

**5-24** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and variable thermal conductivity. The nodal network of the medium consists of nodes 0, 1, and 2 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of this problem for the case of specified heat flux  $\dot{q}_0$  to the wall and convection at the left boundary (node 0) with a convection coefficient of  $h$  and ambient temperature of  $T_\infty$ , and radiation at the right boundary (node 2) with an emissivity of  $\varepsilon$  and surrounding surface temperature of  $T_{\text{surr}}$ .

FIGURE P5-24

**5-25** Consider steady one-dimensional heat conduction in a pin fin of constant diameter  $D$  with constant thermal conductivity. The fin is losing heat by convection to the ambient air at  $T_\infty$  with a heat transfer coefficient of  $h$ . The nodal network of the fin consists of nodes 0 (at the base), 1 (in the middle), and 2 (at the fin tip) with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of this problem to determine  $T_1$  and  $T_2$  for the case of specified temperature at the fin base and negligible heat transfer at the fin tip. All temperatures are in °C.

**5-26** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, 4, and 5 with a uniform nodal spacing of  $\Delta x$ . The temperature at the right boundary (node 5) is specified. Using the energy balance approach, obtain the finite difference formulation of the boundary node 0 on the left boundary for the case of combined convection, radiation, and heat flux at the left boundary with an emissivity of  $\varepsilon$ , convection coefficient of  $h$ , ambient temperature of  $T_\infty$ , surrounding temperature of  $T_{\text{surr}}$ ,

and uniform heat flux of  $\dot{q}_0$ . Also, obtain the finite difference formulation for the rate of heat transfer at the right boundary.

FIGURE P5-26

**5-27** Consider the base plate of a 800 W household iron having a thickness of  $L = 0.6$  cm, base area of  $A = 160 \text{ cm}^2$ , and thermal conductivity of  $k = 20 \text{ W/m}\cdot\text{K}$ . The inner surface of the base plate is subjected to uniform heat flux generated by the resistance heaters inside. When steady operating conditions are reached, the outer surface temperature of the plate is measured to be 85°C. Disregarding any heat loss through the upper part of the iron and taking the nodal spacing to be 0.2 cm, (a) obtain the finite difference formulation for the nodes and (b) determine the inner surface temperature of the plate by solving those equations. *Answer: (b) 100°C*

FIGURE P5-27

**5-28** Consider a large plane wall of thickness  $L = 0.3$  m, thermal conductivity  $k = 2.5 \text{ W/m}\cdot\text{K}$ , and surface area  $A = 24 \text{ m}^2$ . The left side of the wall is subjected to a heat flux of  $\dot{q}_0 = 350 \text{ W/m}^2$  while the temperature at that surface is measured to be  $T_0 = 60^\circ\text{C}$ . Assuming steady one-dimensional heat transfer and taking the nodal spacing to be 6 cm, (a) obtain the finite difference formulation for the six nodes and (b) determine the temperature of the other surface of the wall by solving those equations.

**5-29** Consider a large uranium plate of thickness 5 cm and thermal conductivity  $k = 28 \text{ W/m}\cdot\text{K}$  in which heat is generated uniformly at a constant rate of  $\dot{e} = 6 \times 10^5 \text{ W/m}^3$ . One side of the plate is insulated while the other side is subjected to

convection to an environment at  $30^\circ\text{C}$  with a heat transfer coefficient of  $h = 60 \text{ W/m}^2\cdot\text{K}$ . Considering six equally spaced nodes with a nodal spacing of 1 cm, (a) obtain the finite difference formulation of this problem and (b) determine the nodal temperatures under steady conditions by solving those equations.

**5–30** Repeat Prob. 5–29 using EES (or other) software.

**5–31** Consider a large plane wall of thickness  $L = 0.4 \text{ m}$ , thermal conductivity  $k = 2.3 \text{ W/m}\cdot\text{K}$ , and surface area  $A = 20 \text{ m}^2$ . The left side of the wall is maintained at a constant temperature of  $95^\circ\text{C}$ , while the right side loses heat by convection to the surrounding air at  $T_\infty = 15^\circ\text{C}$  with a heat transfer coefficient of  $h = 18 \text{ W/m}^2\cdot\text{K}$ . Assuming steady one-dimensional heat transfer and taking the nodal spacing to be 10 cm, (a) obtain the finite difference formulation for all nodes, (b) determine the nodal temperatures by solving those equations, and (c) evaluate the rate of heat transfer through the wall.

**5–32E** A large steel plate having a thickness of  $L = 5 \text{ in}$ , thermal conductivity of  $k = 7.2 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ , and an emissivity of  $\varepsilon = 0.6$  is lying on the ground. The exposed surface of the plate exchanges heat by convection with the ambient air at  $T_\infty = 80^\circ\text{F}$  with an average heat transfer coefficient of  $h = 3.5 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$  as well as by radiation with the open sky at an equivalent sky temperature of  $T_{\text{sky}} = 510 \text{ R}$ . The ground temperature below a certain depth (say, 3 ft) is not affected by the weather conditions outside and remains fairly constant at  $50^\circ\text{F}$  at that location. The thermal conductivity of the soil can be taken to be  $k_{\text{soil}} = 0.49 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ , and the steel plate can be assumed to be in perfect contact with the ground. Assuming steady one-dimensional heat transfer and taking the nodal spacings to be 1 in in the plate and 0.6 ft in the ground, (a) obtain the finite difference formulation for all 11 nodes shown in Figure P5–32E and (b) determine the top and bottom surface temperatures of the plate by solving those equations.

FIGURE P5–32E

**5–33E** Repeat Prob. 5–32E by disregarding radiation heat transfer from the upper surface. *Answers: (b)  $78.7^\circ\text{F}$ ,  $78.4^\circ\text{F}$*

**5–34** A 1-m-long and 0.1-m-thick steel plate of thermal conductivity  $35 \text{ W/m}\cdot\text{K}$  is well insulated on its both sides, while the top surface is exposed to a uniform heat flux of  $5500 \text{ W/m}^2$ . The bottom surface is convectively cooled by a fluid at  $10^\circ\text{C}$  having a convective heat transfer coefficient of  $150 \text{ W/m}^2\cdot\text{K}$ . Assuming one dimensional heat conduction in the lateral direction, find the temperature at the midpoint of the plate. Discretize the plate thickness into four equal parts.

**5–35** Consider a 1-D steady state heat conduction in a composite wall made up of two different materials A ( $k = 45 \text{ W/m}\cdot\text{K}$ ) and B ( $k = 28 \text{ W/m}\cdot\text{K}$ ). There is a heating element passing through the material A that causes uniform heat generation at a rate of  $70,000 \text{ W/m}^3$ . The total thickness of the wall is 20 cm with equal thickness of material A and material B. Using a uniform nodal spacing of 2.5 cm, (a) obtain a finite difference formulation for the case of constant uniform heat flux of  $4500 \text{ W/m}^2$  at the wall inner (left) surface while the outer (right) surface is exposed to combined radiation ( $\varepsilon = 0.9$ ) and convection boundary condition ( $h = 70 \text{ W/m}^2\cdot\text{K}$ ). Assume the surrounding temperature equal to that of the ambient temperature at  $10^\circ\text{C}$  and determine (b) the temperature distribution across the wall thickness using boundary conditions in part (a).

**5–36** A stainless steel plane wall ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ) of thickness 1 m experiences a uniform heat generation of  $1000 \text{ W/m}^3$ . The left side of the wall is maintained at a constant temperature of  $70^\circ\text{C}$ , and the right side of the wall is exposed to ambient air temperature of  $0^\circ\text{C}$  with convection heat transfer coefficient of  $250 \text{ W/m}^2\cdot\text{K}$ . Using a uniform nodal spacing of 0.2 m, (a) obtain the finite difference equations and (b) determine the nodal temperatures by solving those equations.

**5–37** Consider a 2-m-long and 0.7-m-wide stainless-steel plate whose thickness is 0.1 m. The left surface of the plate is exposed to a uniform heat flux of  $2000 \text{ W/m}^2$  while the right surface of the plate is exposed to a convective environment at  $0^\circ\text{C}$  with  $h = 400 \text{ W/m}^2\cdot\text{K}$ . The thermal conductivity of the stainless steel plate can be assumed to vary linearly with temperature range as  $k(T) = k_o(1 + \beta T)$  where  $k_o = 48 \text{ W/m}\cdot\text{K}$  and  $\beta = 9.21 \times 10^{-4} \text{ }^\circ\text{C}^{-1}$ . The stainless steel plate experiences a uniform volumetric heat generation at a rate of  $8 \times 10^5 \text{ W/m}^3$ . Assuming steady state one-dimensional heat transfer, determine the temperature distribution along the plate thickness.

**5–38** A plane wall with surface temperature of  $350^\circ\text{C}$  is attached with straight rectangular fins ( $k = 235 \text{ W/m}\cdot\text{K}$ ). The fins are exposed to an ambient air condition of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $154 \text{ W/m}^2\cdot\text{K}$ . Each fin has a length of 50 mm, a base of 5 mm thick, and a width of 100 mm. For a single fin, using a uniform nodal spacing of 10 mm, determine (a) the finite difference equations, (b) the nodal temperatures by solving the finite difference equations, and (c) the heat transfer rate and compare the result with analytical solution.

**FIGURE P5–38**

**5–39** Consider a stainless steel spoon ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ,  $\epsilon = 0.6$ ) that is partially immersed in boiling water at  $95^\circ\text{C}$  in a kitchen at  $25^\circ\text{C}$ . The handle of the spoon has a cross section of about  $0.2 \text{ cm} \times 1 \text{ cm}$  and extends  $18 \text{ cm}$  in the air from the free surface of the water. The spoon loses heat by convection to the ambient air with an average heat transfer coefficient of  $h = 13 \text{ W/m}^2\cdot\text{K}$  as well as by radiation to the surrounding surfaces at an average temperature of  $T_{\text{surr}} = 295 \text{ K}$ . Assuming steady one-dimensional heat transfer along the spoon and taking the nodal spacing to be  $3 \text{ cm}$ , (a) obtain the finite difference formulation for all nodes, (b) determine the temperature of the tip of the spoon by solving those equations, and (c) determine the rate of heat transfer from the exposed surfaces of the spoon.

**5–40** A circular fin of uniform cross section, with diameter of  $10 \text{ mm}$  and length of  $50 \text{ mm}$ , is attached to a wall with surface temperature of  $350^\circ\text{C}$ . The fin is made of material with thermal conductivity of  $240 \text{ W/m}\cdot\text{K}$ , and it is exposed to an ambient air condition of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $250 \text{ W/m}^2\cdot\text{K}$ . Assume steady one-dimensional heat transfer along the fin and the nodal spacing to be uniformly  $10 \text{ mm}$ , (a) using the energy balance approach, obtain the finite difference equations to determine the nodal temperatures, (b) determine the nodal temperatures along the fin by solving those equations and compare the results with the analytical solution, and (c) calculate the heat transfer rate and compare the result with the analytical solution.

**FIGURE P5–40**

**5–41** A cylindrical aluminum fin with adiabatic tip is attached to a wall with surface temperature of  $300^\circ\text{C}$ , and is exposed to ambient air condition of  $15^\circ\text{C}$  with convection heat transfer coefficient of  $150 \text{ W/m}^2\cdot\text{K}$ . The fin has a uniform cross section with diameter of  $1 \text{ cm}$ , length of  $5 \text{ cm}$ , and thermal conductivity of  $237 \text{ W/m}\cdot\text{K}$ . Assume steady

one-dimensional heat transfer along the fin and the nodal spacing to be uniformly  $10 \text{ mm}$ , (a) obtain the finite difference equations for use with the Gauss-Seidel iterative method, and (b) determine the nodal temperatures using the Gauss-Seidel iterative method and compare the results with the analytical solution.

**5–42** A circular fin ( $k = 240 \text{ W/m}\cdot\text{K}$ ) of uniform cross section, with diameter of  $10 \text{ mm}$  and length of  $50 \text{ mm}$ , is attached to a wall with surface temperature of  $350^\circ\text{C}$ . The fin tip has a temperature of  $200^\circ\text{C}$ , and it is exposed to ambient air condition of  $25^\circ\text{C}$  and the convection heat transfer coefficient is  $250 \text{ W/m}^2\cdot\text{K}$ . Assume steady one-dimensional heat transfer along the fin and the nodal spacing to be uniformly  $10 \text{ mm}$ , (a) using the energy balance approach, obtain the finite difference equations to determine the nodal temperatures, and (b) determine the nodal temperatures along the fin by solving those equations and compare the results with the analytical solution.

**5–43** A DC motor delivers mechanical power to a rotating stainless steel shaft ( $k = 15.1 \text{ W/m}\cdot\text{K}$ ) with a length of  $25 \text{ cm}$  and a diameter of  $25 \text{ mm}$ . The DC motor is in a surrounding with ambient air temperature of  $20^\circ\text{C}$  and convection heat transfer coefficient of  $25 \text{ W/m}^2\cdot\text{K}$ , and the base temperature of the motor shaft is  $90^\circ\text{C}$ . Using a uniform nodal spacing of  $5 \text{ cm}$  along the motor shaft, determine the finite difference equations and the nodal temperatures by solving those equations.

**FIGURE P5–43**

**5–44** One side of a  $2\text{-m}$ -high and  $3\text{-m}$ -wide vertical plate at  $80^\circ\text{C}$  is to be cooled by attaching aluminum fins ( $k = 237 \text{ W/m}\cdot\text{K}$ ) of rectangular profile in an environment at  $35^\circ\text{C}$ . The fins are  $2 \text{ cm}$  long,  $0.3 \text{ cm}$  thick, and  $0.4 \text{ cm}$  apart, as shown in Fig. P5–44 on the next page. The heat transfer coefficient between the fins and the surrounding air for combined convection and radiation is estimated to be  $30 \text{ W/m}^2\cdot\text{K}$ . Assuming steady one-dimensional heat transfer along the fin and taking the nodal spacing to be  $0.5 \text{ cm}$ , determine (a) the finite difference formulation of this problem, (b) the nodal temperatures along the fin by solving these equations, (c) the rate of heat transfer from a single fin, and (d) the rate of heat transfer from the entire finned surface of the plate.

FIGURE P5-44

**5-45** A hot surface at 100°C is to be cooled by attaching 3-cm-long, 0.25-cm-diameter aluminum pin fins ( $k = 237 \text{ W/m}\cdot\text{K}$ ) with a center-to-center distance of 0.6 cm. The temperature of the surrounding medium is 30°C, and the combined heat transfer coefficient on the surfaces is 35  $\text{W/m}^2\cdot\text{K}$ . Assuming steady one-dimensional heat transfer along the fin and taking the nodal spacing to be 0.5 cm, determine (a) the finite difference formulation of this problem, (b) the nodal temperatures along the fin by solving these equations, (c) the rate of heat transfer from a single fin, and (d) the rate of heat transfer from a 1-m  $\times$  1-m section of the plate.

FIGURE P5-45

**5-46** Repeat Prob. 5-45 using copper fins ( $k = 386 \text{ W/m}\cdot\text{K}$ ) instead of aluminum ones.

*Answers:* (b) 98.6°C, 97.5°C, 96.7°C, 96.0°C, 95.7°C, 95.5°C

**5-47** Consider an aluminum alloy fin ( $k = 180 \text{ W/m}\cdot\text{K}$ ) of triangular cross section whose length is  $L = 5 \text{ cm}$ , base thickness is  $b = 1 \text{ cm}$ , and width  $w$  in the direction normal to the plane of paper is very large. The base of the fin is maintained at

a temperature of  $T_0 = 180^\circ\text{C}$ . The fin is losing heat by convection to the ambient air at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 25 \text{ W/m}^2\cdot\text{K}$  and by radiation to the surrounding surfaces at an average temperature of  $T_{\text{surr}} = 290 \text{ K}$ . Using the finite difference method with six equally spaced nodes along the fin in the  $x$ -direction, determine (a) the temperatures at the nodes and (b) the rate of heat transfer from the fin for  $w = 1 \text{ m}$ . Take the emissivity of the fin surface to be 0.9 and assume steady one-dimensional heat transfer in the fin.

*Answers:* (a) 177.0°C, 174.1°C, 171.2°C, 168.4°C, 165.5°C; (b) 537 W

FIGURE P5-47

**5-48** Reconsider Prob. 5-47. Using EES (or other) software, investigate the effect of the fin base temperature and the rate of heat transfer from the fin. Let the temperature at the fin base vary from 100°C to 200°C. Plot the fin tip temperature and the rate of heat transfer as a function of the fin base temperature, and discuss the results.

**5-49** Two 3-m-long and 0.4-cm-thick cast iron ( $k = 52 \text{ W/m}\cdot\text{K}$ ,  $\epsilon = 0.8$ ) steam pipes of outer diameter 10 cm are connected to each other through two 1-cm-thick flanges of outer diameter 20 cm. The steam flows inside the pipe at an average temperature of 200°C with a heat transfer coefficient of 180  $\text{W/m}^2\cdot\text{K}$ . The outer surface of the pipe is exposed to convection with ambient air at 8°C with a heat transfer coefficient of 25  $\text{W/m}^2\cdot\text{K}$  as well as radiation with the surrounding surfaces at an average temperature of  $T_{\text{surr}} = 290 \text{ K}$ . Assuming steady one-dimensional heat conduction along the flanges and taking the nodal spacing to be 1 cm along the flange (a) obtain the finite difference formulation for all nodes, (b) determine the temperature at the tip of the flange by solving those equations, and (c) determine the rate of heat transfer from the exposed surfaces of the flange.

FIGURE P5-49

**5-50** Reconsider Prob. 5-49. Using EES (or other) software, investigate the effects of the steam temperature and the outer heat transfer coefficient on the flange tip temperature and the rate of heat transfer from the exposed surfaces of the flange. Let the steam temperature vary from 150°C to 300°C and the heat transfer coefficient from 15 W/m<sup>2</sup>·K to 60 W/m<sup>2</sup>·K. Plot the flange tip temperature and the heat transfer rate as functions of steam temperature and heat transfer coefficient, and discuss the results.

**5-51** Using EES (or other) software, solve these systems of algebraic equations.

$$(a) \begin{aligned} 3x_1 - x_2 + 3x_3 &= 0 \\ -x_1 + 2x_2 + x_3 &= 3 \\ 2x_1 - x_2 - x_3 &= 2 \end{aligned}$$

$$(b) \begin{aligned} 4x_1 - 2x_2^2 + 0.5x_3 &= -2 \\ x_1^3 - x_2 + x_3 &= 11.964 \\ x_1 + x_2 + x_3 &= 3 \end{aligned}$$

Answers: (a)  $x_1 = 2$ ,  $x_2 = 3$ ,  $x_3 = -1$ , (b)  $x_1 = 2.33$ ,  $x_2 = 2.29$ ,  $x_3 = -1.62$

**5-52** Using EES (or other) software, solve these systems of algebraic equations.

$$(a) \begin{aligned} 3x_1 + 2x_2 - x_3 + x_4 &= 6 \\ x_1 + 2x_2 - x_4 &= -3 \\ -2x_1 + x_2 + 3x_3 + x_4 &= 2 \\ 3x_2 + x_3 - 4x_4 &= -6 \end{aligned}$$

$$(b) \begin{aligned} 3x_1 + x_2^2 + 2x_3 &= 8 \\ -x_1^2 + 3x_2 + 2x_3 &= -6.293 \\ 2x_1 - x_2^4 + 4x_3 &= -12 \end{aligned}$$

**5-53** Using EES (or other) software, solve these systems of algebraic equations.

$$(a) \begin{aligned} 4x_1 - x_2 + 2x_3 + x_4 &= -6 \\ x_1 + 3x_2 - x_3 + 4x_4 &= -1 \\ -x_1 + 2x_2 + 5x_4 &= 5 \\ 2x_2 - 4x_3 - 3x_4 &= -5 \end{aligned}$$

$$(b) \begin{aligned} 2x_1 + x_2^4 - 2x_3 + x_4 &= 1 \\ x_1^2 + 4x_2 + 2x_3^2 - 2x_4 &= -3 \\ -x_1 + x_2^4 + 5x_3 &= 10 \\ 3x_1 - x_3^2 + 8x_4 &= 15 \end{aligned}$$

### Two-Dimensional Steady Heat Conduction

**5-54C** What is an irregular boundary? What is a practical way of handling irregular boundary surfaces with the finite difference method?

**5-55C** Consider a medium in which the finite difference formulation of a general interior node is given in its simplest form as

$$T_{\text{node}} = (T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}})/4$$

- (a) Is heat transfer in this medium steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the nodal spacing constant or variable?
- (e) Is the thermal conductivity of the medium constant or variable?

**5-56C** Consider a medium in which the finite difference formulation of a general interior node is given in its simplest form as

$$T_{\text{left}} + T_{\text{top}} + T_{\text{right}} + T_{\text{bottom}} - 4T_{\text{node}} + \frac{\dot{e}_{\text{node}}l^2}{k} = 0$$

- (a) Is heat transfer in this medium steady or transient?
- (b) Is heat transfer one-, two-, or three-dimensional?
- (c) Is there heat generation in the medium?
- (d) Is the nodal spacing constant or variable?
- (e) Is the thermal conductivity of the medium constant or variable?

**5-57** Starting with an energy balance on a volume element, obtain the steady two-dimensional finite difference equation for a general interior node in rectangular coordinates for  $T(x, y)$  for the case of variable thermal conductivity and uniform heat generation.

**5-58** Consider steady two-dimensional heat transfer in a square cross section (3 cm  $\times$  3 cm) with the prescribed temperatures at the top, right, bottom, and left surfaces to be 100°C, 200°C, 300°C, and 500°C, respectively. Using a uniform mesh size  $\Delta x = \Delta y$ , determine (a) the finite difference equations and (b) the nodal temperatures with the Gauss-Seidel iterative method.

FIGURE P5-58

**5-59** Consider steady two-dimensional heat transfer in a long solid body whose cross section is given in the figure. The measured temperatures at selected points of the outer surfaces are as shown. The thermal conductivity of the body is  $k = 45 \text{ W/m}\cdot\text{K}$ , and there is no heat generation. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 2.0 \text{ cm}$ , determine the temperatures at the indicated points in the medium. Hint: Take advantage of symmetry.

FIGURE P5-59

**5-60** Consider steady two-dimensional heat transfer in a long solid bar of (a) square and (b) rectangular cross sections as shown in the figure. The measured temperatures at selected points of the outer surfaces are as shown. The thermal conductivity of the body is  $k = 20 \text{ W/m}\cdot\text{K}$ , and there is no heat generation. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 1.0 \text{ cm}$ , determine the temperatures at the indicated points in the medium.

Answers: (a)  $T_1 = 185^\circ\text{C}$ ,  $T_2 = T_3 = T_4 = 190^\circ\text{C}$

FIGURE P5-60

**5-61** Consider steady two-dimensional heat conduction in a square cross section ( $3 \text{ cm} \times 3 \text{ cm}$ ,  $k = 20 \text{ W/m}\cdot\text{K}$ ,  $\alpha = 6.694 \times 10^{-6} \text{ m}^2/\text{s}$ ) with constant prescribed temperature of  $100^\circ\text{C}$  and  $300^\circ\text{C}$  at the top and bottom surfaces, respectively. The left surface is exposed to a constant heat flux of  $1000 \text{ W/m}^2$  while the right surface is in contact with a convective environment ( $h = 45 \text{ W/m}^2\cdot\text{K}$ ) at  $20^\circ\text{C}$ . Using a uniform mesh size of  $\Delta x = \Delta y$ , determine (a) finite difference equations and (b) the nodal temperatures using Gauss-Seidel iteration method.

FIGURE P5-61

**5-62** Consider steady two-dimensional heat transfer in a rectangular cross section ( $60 \text{ cm} \times 30 \text{ cm}$ ) with the prescribed temperatures at the left, right, and bottom surfaces to be  $0^\circ\text{C}$ , and the top surface is given as  $100\sin(\pi x/60)$ . Using a uniform mesh size  $\Delta x = \Delta y$ , determine (a) the finite difference equations and (b) the nodal temperatures.

FIGURE P5-62

**5-63** Consider a rectangular metal block ( $k = 35 \text{ W/m}\cdot\text{K}$ ) of dimensions  $100 \text{ cm} \times 75 \text{ cm}$  subjected to a sinusoidal temperature variation at its top surface while its bottom surface is insulated. The two sides of the metal block are exposed to a convective environment at  $15^\circ\text{C}$  and having a heat transfer coefficient of  $50 \text{ W/m}^2\cdot\text{K}$ . The sinusoidal temperature distribution at the top surface is given as  $100 \sin(\pi x/L)$ . Using a uniform mesh size of  $\Delta x = \Delta y = 25 \text{ cm}$  determine (a) finite difference equations and (b) the nodal temperatures.

FIGURE P5-63

**5–64** Consider a long bar of rectangular cross section (60 mm by 90 mm on a side) and of thermal conductivity 1 W/m·K. The top surface is exposed to a convection process with air at 100°C and a convection heat transfer coefficient of 100 W/m<sup>2</sup>·K, while the remaining surfaces are maintained at 50°C. Using a grid spacing of 30 mm and the Gauss-Seidel iteration method, determine the temperatures at nodes 1, 2, and 3 shown in Fig. P5–64. Use an initial estimate of 0°C for all the nodal temperatures and a 0.35°C convergence criterion.

FIGURE P5-64

**5–65** Consider steady two-dimensional heat transfer in a long solid body whose cross section is given in Fig. P5–65. The temperatures at the selected nodes and the thermal conditions on the boundaries are as shown. The thermal conductivity of the body is  $k = 180 \text{ W/m}\cdot\text{K}$ , and heat is generated in the body uniformly at a rate of  $\dot{e} = 10^7 \text{ W/m}^3$ . Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 10 \text{ cm}$ , determine (a) the temperatures at nodes 1, 2, 3, and 4 and (b) the rate of heat loss from the top surface through a 1-m-long section of the body.

FIGURE P5-65

**5–66** Repeat Prob. 5–65 using EES (or other) software.

**5–67** Reconsider Prob. 5–65. Using EES (or other) software, investigate the effects of the thermal conductivity and the heat generation rate on the temperatures at nodes 1 and 3, and the rate of heat loss from the top surface. Let the thermal conductivity vary from 10 W/m·K to 400 W/m·K and the heat generation rate from  $10^5 \text{ W/m}^3$  to  $10^8 \text{ W/m}^3$ . Plot the temperatures at nodes 1 and 3, and the rate of heat loss as functions of thermal conductivity and heat generation rate, and discuss the results.

**5–68** Consider steady two-dimensional heat transfer in a long solid body whose cross section is given in the figure. The temperatures at the selected nodes and the thermal conditions at the boundaries are as shown. The thermal conductivity of the body is  $k = 45 \text{ W/m}\cdot\text{K}$ , and heat is generated in the body uniformly at a rate of  $\dot{e} = 4 \times 10^6 \text{ W/m}^3$ . Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 5 \text{ cm}$ , determine (a) the temperatures at nodes 1, 2, and 3 and (b) the rate of heat loss from the bottom surface through a 1-m-long section of the body.

FIGURE P5-68

**5-69**  Repeat Prob. 5-68 using EES (or other) software.

**5-70** Consider a 5-m-long constantan block ( $k = 23 \text{ W/m}\cdot\text{K}$ ) 30 cm high and 50 cm wide (Fig. P5-70). The block is completely submerged in iced water at  $0^\circ\text{C}$  that is well stirred, and the heat transfer coefficient is so high that the temperatures on both sides of the block can be taken to be  $0^\circ\text{C}$ . The bottom surface of the bar is covered with a low-conductivity material so that heat transfer through the bottom surface is negligible. The top surface of the block is heated uniformly by a 8-kW resistance heater. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 10 \text{ cm}$  and taking advantage of symmetry, (a) obtain the finite difference formulation of this problem for steady two-dimensional heat transfer, (b) determine the unknown nodal temperatures by solving those equations, and (c) determine the rate of heat transfer from the block to the iced water.

FIGURE P5-70

**5-71** Consider steady two-dimensional heat transfer in a long solid bar ( $k = 25 \text{ W/m}\cdot\text{K}$ ) of square cross section ( $3 \text{ cm} \times 3 \text{ cm}$ ) with the prescribed temperatures at the top, right, bottom, and left surfaces to be  $100^\circ\text{C}$ ,  $200^\circ\text{C}$ ,  $300^\circ\text{C}$ , and  $500^\circ\text{C}$ , respectively. Heat is generated in the bar uniformly at a rate of  $\dot{e} = 5 \times 10^6 \text{ W/m}^3$ . Using a uniform mesh size  $\Delta x = \Delta y = 1 \text{ cm}$  determine (a) the finite difference equations and (b) the nodal temperatures with the Gauss-Seidel iterative method.

FIGURE P5-71

**5-72E** Consider steady two-dimensional heat transfer in a long solid bar of square cross section in which heat is generated uniformly at a rate of  $\dot{e} = 0.19 \times 10^5 \text{ Btu/h}\cdot\text{ft}^3$ . The cross section of the bar is  $0.5 \text{ ft} \times 0.5 \text{ ft}$  in size, and its thermal conductivity is  $k = 16 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ . All four sides of the bar are subjected to convection with the ambient air at  $T_\infty = 70^\circ\text{F}$  with a heat transfer coefficient of  $h = 7.9 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ . Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 0.25 \text{ ft}$ , determine (a) the temperatures at the nine nodes and (b) the rate of heat loss from the bar through a 1-ft-long section.

Answer: (b) 4750 Btu/h

FIGURE P5-72E

**5-73** Hot combustion gases of a furnace are flowing through a concrete chimney ( $k = 1.4 \text{ W/m}\cdot\text{K}$ ) of rectangular cross section. The flow section of the chimney is  $20 \text{ cm} \times 40 \text{ cm}$ , and the thickness of the wall is 10 cm. The average temperature of the hot gases in the chimney is  $T_i = 280^\circ\text{C}$ , and the average convection heat transfer coefficient inside the chimney is  $h_i = 75 \text{ W/m}^2\cdot\text{K}$ . The chimney is losing heat from its outer surface to the ambient air at  $T_o = 15^\circ\text{C}$  by convection with a heat transfer coefficient of  $h_o = 18 \text{ W/m}^2\cdot\text{K}$  and to the sky by radiation. The emissivity of the outer surface of the wall is  $\varepsilon = 0.9$ , and the effective sky temperature is estimated to be 250 K.

FIGURE P5-73

Using the finite difference method with  $\Delta x = \Delta y = 10 \text{ cm}$  and taking full advantage of symmetry, (a) obtain the finite difference formulation of this problem for steady two-dimensional heat transfer, (b) determine the temperatures at the nodal points of a cross section, and (c) evaluate the rate of heat loss for a 1-m-long section of the chimney.

**5-74** Repeat Prob. 5-73 by disregarding radiation heat transfer from the outer surfaces of the chimney.

**5-75** A thin film 500 W electrical heater of negligible thickness and dimensions  $100 \text{ mm} \times 100 \text{ mm}$  is sandwiched between two slabs made of copper alloy ( $k = 120 \text{ W/m}\cdot\text{K}$ ) and stainless steel ( $15 \text{ W/m}\cdot\text{K}$ ). The two plates, copper and stainless steel with thickness 50 mm and 50 mm are surrounded by air with heat transfer coefficients of  $75 \text{ W/m}^2\cdot\text{K}$  and  $25 \text{ W/m}^2\cdot\text{K}$ , respectively. The plates are subjected to a constant temperature of  $50^\circ\text{C}$  and  $30^\circ\text{C}$  at the top and the bottom surface, respectively as shown in Fig. P5-75. The temperature of the surrounding air is maintained at  $20^\circ\text{C}$ . Determine (a) finite difference formulation at each node and (b) the location of maximum temperature.

FIGURE P5-75

**5-76** The wall of a heat exchanger separates hot water at  $T_A = 90^\circ\text{C}$  from cold water at  $T_B = 10^\circ\text{C}$ . To extend the heat transfer area, two-dimensional ridges are machined on the cold side of the wall, as shown in Fig. P5-76. This geometry causes non-uniform thermal stresses, which may become critical for crack initiation along the lines between two ridges. To predict thermal stresses, the temperature field inside the wall must be determined. Convection coefficients are high enough so that the surface temperature is equal to that of the water on each side of the wall.

- Identify the smallest section of the wall that can be analyzed in order to find the temperature field in the whole wall.
- For the domain found in part (a), construct a two-dimensional grid with  $\Delta x = \Delta y = 5 \text{ mm}$  and write the

matrix equation  $AT = C$  (elements of matrices  $A$  and  $C$  must be numbers). Do not solve for  $T$ .

(c) A thermocouple mounted at point  $M$  reads  $46.9^\circ\text{C}$ . Determine the other unknown temperatures in the grid defined in part (b).

FIGURE P5-76

**5-77** Consider steady two-dimensional heat transfer in two long solid bars whose cross sections are given in the figure. The measured temperatures at selected points on the outer surfaces are as shown. The thermal conductivity of the body is  $k = 20 \text{ W/m}\cdot\text{K}$ , and there is no heat generation. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 1.0 \text{ cm}$ , determine the temperatures at the indicated points in the medium. Hint: Take advantage of symmetry.

Answers: (b)  $T_1 = T_4 = 93^\circ\text{C}$ ,  $T_2 = T_3 = 86^\circ\text{C}$

FIGURE P5-77

**5-78** Consider a long concrete dam ( $k = 0.6 \text{ W/m}\cdot\text{K}$ ,  $\alpha_s = 0.7$ ) of triangular cross section whose exposed surface is subjected to solar heat flux of  $\dot{q}_s = 800 \text{ W/m}^2$  and to convection and radiation to the environment at  $25^\circ\text{C}$  with a combined heat transfer coefficient of  $30 \text{ W/m}^2\cdot\text{K}$ . The 2-m-high vertical section of the dam is subjected to convection by water at  $15^\circ\text{C}$  with a heat transfer coefficient of  $150 \text{ W/m}^2\cdot\text{K}$ , and heat transfer through the 2-m-long base is considered to be negligible. Using the finite

difference method with a mesh size of  $\Delta x = \Delta y = 1$  m and assuming steady two-dimensional heat transfer, determine the temperature of the top, middle, and bottom of the exposed surface of the dam. *Answers: 21.3°C, 43.2°C, 43.6°C*

**FIGURE P5-78**

**5-79** Consider a long solid bar whose thermal conductivity is  $k = 5$  W/m·K and whose cross section is given in the figure. The top surface of the bar is maintained at 50°C while the bottom surface is maintained at 120°C. The left surface is insulated and the remaining three surfaces are subjected to convection with ambient air at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 40$  W/m<sup>2</sup>·K. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 10$  cm, (a) obtain the finite difference formulation of this problem for steady two-dimensional heat transfer and (b) determine the unknown nodal temperatures by solving those equations.

*Answers: (b) 78.8°C, 72.7°C, 64.6°C*

**FIGURE P5-79**

**5-80** Consider steady two-dimensional heat transfer in an L-shaped solid body whose cross section is given in the figure. The thermal conductivity of the body is  $k = 45$  W/m·K, and heat is generated in the body at a rate of  $\dot{q} = 5 \times 10^6$  W/m<sup>3</sup>. The right surface of the body is insulated, and the bottom surface is maintained at a uniform temperature of 120°C. The entire top surface is subjected to convection with ambient air at  $T_\infty = 30^\circ\text{C}$  with a heat transfer coefficient of  $h = 55$  W/m<sup>2</sup>·K, and the left surface is subjected to heat flux at a uniform rate of  $\dot{q}_L = 8000$  W/m<sup>2</sup>. The nodal network of the problem consists of 13 equally spaced nodes with  $\Delta x = \Delta y = 1.5$  cm. Five of the nodes are at the bottom surface and thus their temperatures

are known. (a) Obtain the finite difference equations at the remaining eight nodes and (b) determine the nodal temperatures by solving those equations.

**FIGURE P5-80**

**5-81** As shown in Fig. P5-81 a T shaped bar ( $k = 28$  W/m·K) in inverted position is attached to a surface maintained at 200°C. The two sides of the bottom portion of the T bar are insulated while the rest of the sides are subjected to a convective environment with  $h = 30$  W/m<sup>2</sup>·K and ambient temperature of 10°C. The mesh size is uniform for the long portion of the bar while it is doubled in x direction for the bottom portion of the T bar. Assuming steady state conditions and no internal heat generation determine (a) the finite difference formulation for each node and (b) the nodal temperatures. Hint: Take advantage of symmetry.

**FIGURE P5-81**

**5-82** Sintering is a metallurgical process used to create metal objects with better physical properties by holding powdered material in a mold and heating it to a temperature slightly below its melting point. Two materials nickel ( $k = 90.7$  W/m·K) and copper ( $k = 401$  W/m·K) are embedded in a mold made of stainless steel ( $k = 15.1$  W/m·K), as shown in Fig. P5-82. The bottom surface of stainless steel is maintained at a non-uniform temperature while its two sides are insulated. The upper surface of nickel and copper is exposed to

a convective environment with  $h = 125 \text{ W/m}^2\cdot\text{K}$  and ambient temperature of  $15^\circ\text{C}$ . Assuming steady state heat conduction and a mesh size of 1.5 cm, develop finite difference equations for different nodes and determine the nodal temperatures. The density of the powered material after sintering is about 99% of the original metal density and hence may be considered as a continuous solid material for all practical purposes. Hint: Use mirror image concept for the nodes at insulated boundary.

**FIGURE P5-82**

**5-83E** Consider steady two-dimensional heat transfer in a V-grooved solid body whose cross section is given in the figure. The top surfaces of the groove are maintained at  $32^\circ\text{F}$  while the bottom surface is maintained at  $212^\circ\text{F}$ . The side surfaces of the groove are insulated. Using the finite difference method with a mesh size of  $\Delta x = \Delta y = 1 \text{ ft}$  and taking advantage of symmetry, determine the temperatures at the middle of the insulated surfaces.

**FIGURE P5-83E**

**5-84E** Reconsider Prob. 5-83E. Using EES (or other software), investigate the effects of the temperatures at the top and bottom surfaces on the temperature in the middle of the insulated surface. Let the temperatures at the top and bottom surfaces vary from  $32^\circ\text{F}$  to  $212^\circ\text{F}$ . Plot the temperature in the middle of the insulated surface as functions of the temperatures at the top and bottom surfaces, and discuss the results.

### Transient Heat Conduction

**5-85C** How does the finite difference formulation of a transient heat conduction problem differ from that of a steady heat

conduction problem? What does the term  $\rho A \Delta x c_p (T_m^{i+1} - T_m^i) / \Delta t$  represent in the transient finite difference formulation?

**5-86C** What are the two basic methods of solution of transient problems based on finite differencing? How do heat transfer terms in the energy balance formulation differ in the two methods?

**5-87C** The explicit finite difference formulation of a general interior node for transient heat conduction in a plane wall is given by

$$T_{m-1}^i - 2T_m^i + T_{m+1}^i + \frac{\dot{e}_m^i \Delta x^2}{k} = \frac{T_m^{i+1} - T_m^i}{\tau}$$

Obtain the finite difference formulation for the steady case by simplifying the relation above.

**5-88C** Consider transient one-dimensional heat conduction in a plane wall that is to be solved by the explicit method. If both sides of the wall are at specified temperatures, express the stability criterion for this problem in its simplest form.

**5-89C** Consider transient one-dimensional heat conduction in a plane wall that is to be solved by the explicit method. If both sides of the wall are subjected to specified heat flux, express the stability criterion for this problem in its simplest form.

**5-90C** The explicit finite difference formulation of a general interior node for transient two-dimensional heat conduction is given by

$$\begin{aligned} T_{\text{node}}^{i+1} = & \tau(T_{\text{left}}^i + T_{\text{top}}^i + T_{\text{right}}^i + T_{\text{bottom}}^i) \\ & + (1 - 4\tau)T_{\text{node}}^i + \tau \frac{\dot{e}_{\text{node}}^i l^2}{k} \end{aligned}$$

Obtain the finite difference formulation for the steady case by simplifying the relation above.

**5-91C** Is there any limitation on the size of the time step  $\Delta t$  in the solution of transient heat conduction problems using (a) the explicit method and (b) the implicit method?

**5-92C** Express the general stability criterion for the explicit method of solution of transient heat conduction problems.

**5-93C** Consider transient two-dimensional heat conduction in a rectangular region that is to be solved by the explicit method. If all boundaries of the region are either insulated or at specified temperatures, express the stability criterion for this problem in its simplest form.

**5-94C** The implicit method is unconditionally stable and thus any value of time step  $\Delta t$  can be used in the solution of transient heat conduction problems. To minimize the computation time, someone suggests using a very large value of  $\Delta t$  since there is no danger of instability. Do you agree with this suggestion? Explain.

**5-95** Starting with an energy balance on a volume element, obtain the two-dimensional transient explicit finite difference equation for a general interior node in rectangular coordinates

for  $T(x, y, t)$  for the case of constant thermal conductivity and no heat generation.

**5-96** Starting with an energy balance on a volume element, obtain the two-dimensional transient implicit finite difference equation for a general interior node in rectangular coordinates for  $T(x, y, t)$  for the case of constant thermal conductivity and no heat generation.

**5-97** Starting with an energy balance on a disk volume element, derive the one-dimensional transient explicit finite difference equation for a general interior node for  $T(z, t)$  in a cylinder whose side surface is insulated for the case of constant thermal conductivity with uniform heat generation.

**5-98** Consider transient heat conduction in a plane wall whose left surface (node 0) is maintained at  $50^\circ\text{C}$  while the right surface (node 6) is subjected to a solar heat flux of  $600 \text{ W/m}^2$ . The wall is initially at a uniform temperature of  $50^\circ\text{C}$ . Express the explicit finite difference formulation of the boundary nodes 0 and 6 for the case of no heat generation. Also, obtain the finite difference formulation for the total amount of heat transfer at the left boundary during the first three time steps.

**5-99** Consider transient heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, and 4 with a uniform nodal spacing of  $\Delta x$ . The wall is initially at a specified temperature. Using the energy balance approach, obtain the explicit finite difference formulation of the boundary nodes for the case of uniform heat flux  $\dot{q}_0$  at the left boundary (node 0) and convection at the right boundary (node 4) with a convection coefficient of  $h$  and an ambient temperature of  $T_\infty$ . Do not simplify.

FIGURE P5-99

**5-100** Repeat Prob. 5-99 for the case of implicit formulation.

**5-101** Consider transient heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, 4, and 5 with a uniform nodal spacing of  $\Delta x$ . The wall is initially at a specified temperature. Using the energy balance approach, obtain the explicit finite difference formulation of the boundary nodes for the case of insulation at the left boundary (node 0) and radiation at the right boundary (node 5) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{surr}}$ .

**5-102** Consider transient heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, 3, and 4 with a uniform nodal spacing of  $\Delta x$ . The wall is initially at a specified temperature. The temperature at the right boundary (node 4) is specified. Using the energy balance approach, obtain the explicit finite difference formulation of the boundary node 0 for the case of combined convection, radiation, and heat flux at the left boundary with an emissivity of  $\varepsilon$ , convection coefficient of  $h$ , ambient temperature of  $T_\infty$ , surrounding temperature of  $T_{\text{surr}}$ , and uniform heat flux of  $\dot{q}_0$  toward the wall. Also, obtain the finite difference formulation for the total amount of heat transfer at the right boundary for the first 20 time steps.

FIGURE P5-102

**5-103** Consider one-dimensional transient heat conduction in a composite plane wall that consists of two layers A and B with perfect contact at the interface. The wall involves no heat generation and initially is at a specified temperature. The nodal network of the medium consists of nodes 0, 1 (at the interface), and 2 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the explicit finite difference formulation of this problem for the case of insulation at the left boundary (node 0) and radiation at the right boundary (node 2) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{surr}}$ .

FIGURE P5-103

**5–104** Consider transient one-dimensional heat conduction in a pin fin of constant diameter  $D$  with constant thermal conductivity. The fin is losing heat by convection to the ambient air at  $T_\infty$  with a heat transfer coefficient of  $h$  and by radiation to the surrounding surfaces at an average temperature of  $T_{\text{sur}}$ . The nodal network of the fin consists of nodes 0 (at the base), 1 (in the middle), and 2 (at the fin tip) with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the explicit finite difference formulation of this problem for the case of a specified temperature at the fin base and negligible heat transfer at the fin tip.

**5–105** Repeat Prob. 5–104 for the case of implicit formulation.

**5–106** A hot brass plate is having its upper surface cooled by impinging jet of air at temperature of  $15^\circ\text{C}$  and convection heat transfer coefficient of  $220 \text{ W/m}^2\cdot\text{K}$ . The 10-cm-thick brass plate ( $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 380 \text{ J/kg}\cdot\text{K}$ ,  $k = 110 \text{ W/m}\cdot\text{K}$ , and  $\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$ ) had a uniform initial temperature of  $650^\circ\text{C}$ , and the lower surface of the plate is insulated. Using a uniform nodal spacing of  $\Delta x = 2.5 \text{ cm}$  and time step of  $\Delta t = 10 \text{ s}$  determine (a) the implicit finite difference equations and (b) the nodal temperatures of the brass plate after 10 seconds of cooling.

FIGURE P5–106

**5–107** Consider a large uranium plate of thickness  $L = 9 \text{ cm}$ , thermal conductivity  $k = 28 \text{ W/m}\cdot\text{K}$ , and thermal diffusivity  $\alpha = 12.5 \times 10^{-6} \text{ m}^2/\text{s}$  that is initially at a uniform temperature of  $100^\circ\text{C}$ . Heat is generated uniformly in the plate at a constant rate of  $\dot{e} = 10^6 \text{ W/m}^3$ . At time  $t = 0$ , the left side of the plate is insulated while the other side is subjected to convection with an environment at  $T_\infty = 20^\circ\text{C}$  with a heat transfer coefficient of  $h = 35 \text{ W/m}^2\cdot\text{K}$ . Using the explicit finite difference approach with a uniform nodal spacing of  $\Delta x = 1.5 \text{ cm}$ , determine (a) the temperature distribution in the plate after 5 min and (b) how long it will take for steady conditions to be reached in the plate.

**5–108** Reconsider Prob. 5–107. Using EES (or other) software, investigate the effect of the cooling time

on the temperatures of the left and right sides of the plate. Let the time vary from 5 min to 60 min. Plot the temperatures at the left and right surfaces as a function of time, and discuss the results.

**5–109E** Consider a house whose windows are made of  $0.375\text{-in-thick}$  glass ( $k = 0.48 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$  and  $\alpha = 4.2 \times 10^{-6} \text{ ft}^2/\text{s}$ ). Initially, the entire house, including the walls and the windows, is at the outdoor temperature of  $T_o = 35^\circ\text{F}$ . It is observed that the windows are fogged because the indoor temperature is below the dew-point temperature of  $54^\circ\text{F}$ . Now the heater is turned on and the air temperature in the house is raised to  $T_i = 72^\circ\text{F}$  at a rate of  $2^\circ\text{F}$  rise per minute. The heat transfer coefficients at the inner and outer surfaces of the wall can be taken to be  $h_i = 1.2$  and  $h_o = 2.6 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ , respectively, and the outdoor temperature can be assumed to remain constant. Using the explicit finite difference method with a mesh size of  $\Delta x = 0.125 \text{ in}$ , determine how long it will take for the fog on the windows to clear up (i.e., for the inner surface temperature of the window glass to reach  $54^\circ\text{F}$ ).

FIGURE P5–109E

**5–110** The roof of a house consists of a  $15\text{-cm-thick}$  concrete slab ( $k = 1.4 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.69 \times 10^{-6} \text{ m}^2/\text{s}$ ) that is  $18 \text{ m}$  wide and  $32 \text{ m}$  long. One evening at 6 PM, the slab is observed

FIGURE P5–110

to be at a uniform temperature of 18°C. The average ambient air and the night sky temperatures for the entire night are predicted to be 6°C and 260 K, respectively. The convection heat transfer coefficients at the inner and outer surfaces of the roof can be taken to be  $h_i = 5$  and  $h_o = 12 \text{ W/m}^2\cdot\text{K}$ , respectively. The house and the interior surfaces of the walls and the floor are maintained at a constant temperature of 20°C during the night, and the emissivity of both surfaces of the concrete roof is 0.9. Considering both radiation and convection heat transfers and using the explicit finite difference method with a time step of  $\Delta t = 5 \text{ min}$  and a mesh size of  $\Delta x = 3 \text{ cm}$ , determine the temperatures of the inner and outer surfaces of the roof at 6 AM. Also, determine the average rate of heat transfer through the roof during that night.

**5–111** Consider a refrigerator whose outer dimensions are  $1.80 \text{ m} \times 0.8 \text{ m} \times 0.7 \text{ m}$ . The walls of the refrigerator are constructed of 3-cm-thick urethane insulation ( $k = 0.026 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.36 \times 10^{-6} \text{ m}^2/\text{s}$ ) sandwiched between two layers of sheet metal with negligible thickness. The refrigerated space is maintained at 3°C and the average heat transfer coefficients at the inner and outer surfaces of the wall are  $6 \text{ W/m}^2\cdot\text{K}$  and  $9 \text{ W/m}^2\cdot\text{K}$ , respectively. Heat transfer through the bottom surface of the refrigerator is negligible. The kitchen temperature remains constant at about 25°C. Initially, the refrigerator contains 15 kg of food items at an average specific heat of  $3.6 \text{ kJ/kg}\cdot\text{K}$ . Now a malfunction occurs and the refrigerator stops running for 6 h as a result. Assuming the temperature of the contents of the refrigerator, including the air inside, rises uniformly during this period, predict the temperature inside the refrigerator after 6 h when the repair-man arrives. Use the explicit finite difference method with a time step of  $\Delta t = 1 \text{ min}$  and a mesh size of  $\Delta x = 1 \text{ cm}$  and disregard corner effects (i.e., assume one-dimensional heat transfer in the walls).

**5–112**  Reconsider Prob. 5–111. Using EES (or other) software, plot the temperature inside the refrigerator as a function of heating time as time varies from 1 h to 10 h, and discuss the results.

**5–113** Consider two-dimensional transient heat transfer in an L-shaped solid bar that is initially at a uniform temperature of 140°C and whose cross section is given in the figure. The thermal conductivity and diffusivity of the body are  $k = 15 \text{ W/m}\cdot\text{K}$  and  $\alpha = 3.2 \times 10^{-6} \text{ m}^2/\text{s}$ , respectively, and heat is generated in the body at a rate of  $\dot{e} = 2 \times 10^7 \text{ W/m}^3$ . The right surface of the body is insulated, and the bottom surface is maintained at a uniform temperature of 140°C at all times. At time  $t = 0$ , the entire top surface is subjected to convection with ambient air at  $T_\infty = 25^\circ\text{C}$  with a heat transfer coefficient of  $h = 80 \text{ W/m}^2\cdot\text{K}$ , and the left surface is subjected to uniform heat flux at a rate of  $\dot{q}_L = 8000 \text{ W/m}^2$ . The nodal network of the problem consists of 13 equally spaced nodes with  $\Delta x = \Delta y = 1.5 \text{ cm}$ . Using the explicit method, determine the temperature at the top corner (node 3) of the body after 2, 5, and 30 min.

FIGURE P5–113

**5–114**  Reconsider Prob. 5–113. Using EES (or other) software, plot the temperature at the top corner as a function of heating time as it varies from 2 min to 30 min, and discuss the results.

**5–115** Consider a long solid bar ( $k = 28 \text{ W/m}\cdot\text{K}$  and  $\alpha = 12 \times 10^{-6} \text{ m}^2/\text{s}$ ) of square cross section that is initially at a uniform temperature of 32°C. The cross section of the bar is 20 cm × 20 cm in size, and heat is generated in it uniformly at a rate of  $\dot{e} = 8 \times 10^5 \text{ W/m}^3$ . All four sides of the bar are subjected to convection to the ambient air at  $T_\infty = 30^\circ\text{C}$  with a heat transfer coefficient of  $h = 45 \text{ W/m}^2\cdot\text{K}$ . Using the explicit finite difference method with a mesh size of  $\Delta x = \Delta y = 10 \text{ cm}$ , determine the centerline temperature of the bar (a) after 20 min and (b) after steady conditions are established.

FIGURE P5–115

**5–116** A common annoyance in cars in winter months is the formation of fog on the glass surfaces that blocks the view. A practical way of solving this problem is to blow hot air or to attach electric resistance heaters to the inner surfaces. Consider the rear window of a car that consists of a 0.4-cm-thick glass ( $k = 0.84 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.39 \times 10^{-6} \text{ m}^2/\text{s}$ ). Strip heater wires of negligible thickness are attached to the inner surface of the glass, 4 cm apart. Each wire generates heat at a rate of 25 W/m length. Initially the entire car, including its windows, is at the outdoor temperature of  $T_o = -3^\circ\text{C}$ . The heat transfer coefficients at the inner and outer surfaces of the glass can be taken to be  $h_i = 6$  and  $h_o = 20 \text{ W/m}^2\cdot\text{K}$ , respectively. Using the explicit finite difference method with a mesh size of  $\Delta x = 0.2 \text{ cm}$  along the thickness and  $\Delta y = 1 \text{ cm}$  in the direction normal to the heater wires, determine the temperature distribution throughout the glass 15 min after the strip heaters are

turned on. Also, determine the temperature distribution when steady conditions are reached.

**FIGURE P5–116**

**5–117** Repeat Prob. 5–116 using the implicit method with a time step of 1 min.

**5–118** Revisit Prob. 5–61 of two-dimensional heat conduction in a square cross section. (a) Develop an explicit finite difference formulation for a two-dimensional transient heat conduction case and (b) find the nodal temperatures after 15 seconds.

**5–119** Quench hardening is a mechanical process in which the ferrous metals or alloys are first heated and then quickly cooled down to improve their physical properties and avoid phase transformation. Consider a  $40\text{ cm} \times 20\text{ cm}$  block of copper alloy ( $k = 120\text{ W/m}\cdot\text{K}$ ,  $\alpha = 3.91 \times 10^{-6}\text{ m}^2/\text{s}$ ) being heated uniformly until it reaches a temperature of  $800^\circ\text{C}$ . It is then suddenly immersed into the water bath maintained at  $15^\circ\text{C}$  with  $h = 100\text{ W/m}^2\cdot\text{K}$  for quenching process. However, the upper surface of the metal is not submerged in the water and is exposed to air at  $15^\circ\text{C}$  with a convective heat transfer coefficient of  $10\text{ W/m}^2\cdot\text{K}$ . Using an explicit finite difference formulation, calculate the temperature distribution in the copper alloy block after 10 min have elapsed using  $\Delta t = 10\text{ s}$  and a uniform mesh size of  $\Delta x = \Delta y = 10\text{ cm}$ .

**FIGURE P5–119**

**5–120** Consider a  $2\text{ cm} \times 4\text{ cm}$  ceramic strip ( $k = 3\text{ W/m}\cdot\text{K}$ ,  $\rho = 1600\text{ kg/m}^3$  and  $c_p = 800\text{ J/kg}\cdot\text{K}$ ) embedded in very high conductivity material as shown in Fig. P5–120. The two sides of the ceramic strip are maintained at a constant temperature of  $300^\circ\text{C}$ . The bottom surface of the strip is insulated while the top surface is exposed to a convective environment with  $h = 200\text{ W/m}^2\cdot\text{K}$  and ambient temperature of  $50^\circ\text{C}$ . Initially at  $t = 0$ , the ceramic strip is at a uniform temperature of  $300^\circ\text{C}$ . Using implicit finite difference formulation and a time step of 2 seconds, determine the nodal temperatures after 12 seconds for a uniform mesh size of 1 cm.

**FIGURE P5–120**

### Special Topic: Controlling the Numerical Error

**5–121C** Why do the results obtained using a numerical method differ from the exact results obtained analytically? What are the causes of this difference?

**5–122C** What is the cause of the discretization error? How does the global discretization error differ from the local discretization error?

**5–123C** Can the global (accumulated) discretization error be less than the local error during a step? Explain.

**5–124C** How is the finite difference formulation for the first derivative related to the Taylor series expansion of the solution function?

**5–125C** Explain why the local discretization error of the finite difference method is proportional to the square of the step size. Also explain why the global discretization error is proportional to the step size itself.

**5–126C** What causes the round-off error? What kind of calculations are most susceptible to round-off error?

**5–127C** What happens to the discretization and the round-off errors as the step size is decreased?

**5–128C** Suggest some practical ways of reducing the round-off error.

**5–129C** What is a practical way of checking if the round-off error has been significant in calculations?

**5–130C** What is a practical way of checking if the discretization error has been significant in calculations?

## Review Problems

**5–131** Starting with an energy balance on the volume element, obtain the steady three-dimensional finite difference equation for a general interior node in rectangular coordinates for  $T(x, y, z)$  for the case of constant thermal conductivity and uniform heat generation.

**5–132** Starting with an energy balance on the volume element, obtain the three-dimensional transient explicit finite difference equation for a general interior node in rectangular coordinates for  $T(x, y, z, t)$  for the case of constant thermal conductivity and no heat generation.

**5–133** Consider steady one-dimensional heat conduction in a plane wall with variable heat generation and constant thermal conductivity. The nodal network of the medium consists of nodes 0, 1, 2, and 3 with a uniform nodal spacing of  $\Delta x$ . The temperature at the left boundary (node 0) is specified. Using the energy balance approach, obtain the finite difference formulation of boundary node 3 at the right boundary for the case of combined convection and radiation with an emissivity of  $\varepsilon$ , convection coefficient of  $h$ , ambient temperature of  $T_\infty$ , and surrounding temperature of  $T_{\text{sur}}^*$ . Also, obtain the finite difference formulation for the rate of heat transfer at the left boundary.

FIGURE P5–133

**5–134** Consider one-dimensional transient heat conduction in a plane wall with variable heat generation and variable thermal conductivity. The nodal network of the medium consists of nodes 0, 1, and 2 with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the explicit finite difference formulation of this problem for the case of specified heat flux  $\dot{q}_0$  and convection at the left boundary (node 0) with a convection coefficient of  $h$  and ambient temperature of  $T_\infty$ , and radiation at the right boundary (node 2) with an emissivity of  $\varepsilon$  and surrounding temperature of  $T_{\text{sur}}$ .

**5–135** Repeat Prob. 5–134 for the case of implicit formulation.

**5–136** Consider steady one-dimensional heat conduction in a pin fin of constant diameter  $D$  with constant thermal conductivity. The fin is losing heat by convection with the ambient air

at  $T_\infty$  (in °C) with a convection coefficient of  $h$ , and by radiation to the surrounding surfaces at an average temperature of  $T_{\text{sur}}$  (in K). The nodal network of the fin consists of nodes 0 (at the base), 1 (in the middle), and 2 (at the fin tip) with a uniform nodal spacing of  $\Delta x$ . Using the energy balance approach, obtain the finite difference formulation of this problem for the case of a specified temperature at the fin base and convection and radiation heat transfer at the fin tip.

FIGURE P5–136

**5–137E** Consider a large plane wall of thickness  $L = 0.3$  ft and thermal conductivity  $k = 1.2$  Btu/h·ft·°F in space. The wall is covered with a material having an emissivity of  $\varepsilon = 0.80$  and a solar absorptivity of  $\alpha_s = 0.60$ . The inner surface of the wall is maintained at 520 R at all times, while the outer surface is exposed to solar radiation that is incident at a rate of  $\dot{q}_s = 350$  Btu/h·ft<sup>2</sup>. The outer surface is also losing heat by radiation to deep space at 0 R. Using a uniform nodal spacing of  $\Delta x = 0.1$  ft, (a) obtain the finite difference formulation for steady one-dimensional heat conduction and (b) determine the nodal temperatures by solving those equations.

Answers: (b) 528 R, 535 R, 543 R

FIGURE P5–137E

**5–138** Consider a nuclear fuel element ( $k = 57$  W/m·K) that can be modeled as a plane wall with thickness of 4 cm. The fuel element generates  $3 \times 10^7$  W/m<sup>3</sup> of heat uniformly. Both side surfaces of the fuel element are cooled by liquid with temperature of 80°C and convection heat transfer coefficient of 8000 W/m<sup>2</sup>·K. Using a uniform nodal spacing of 8 mm, (a) obtain the finite difference equations, (b) determine the nodal temperatures by solving those equations, and (c) compare the surface temperatures of both sides of the fuel element with analytical solution.

FIGURE P5-138

**5-139** A fuel element ( $k = 67 \text{ W/m}\cdot\text{K}$ ) that can be modeled as a plane wall has a thickness of 4 cm. The fuel element generates  $5 \times 10^7 \text{ W/m}^3$  of heat uniformly. Both side surfaces of the fuel element are cooled by liquid with temperature of  $90^\circ\text{C}$  and convection heat transfer coefficient of  $5000 \text{ W/m}^2\cdot\text{K}$ . Use a uniform nodal spacing of 4 mm and make use of the symmetry line at the center of the plane wall, determine (a) the finite difference equations and (b) the nodal temperatures by solving those equations.

**5-140** Consider steady two-dimensional heat transfer in a long solid bar ( $k = 25 \text{ W/m}\cdot\text{K}$ ) of square cross section ( $2 \text{ cm} \times 2 \text{ cm}$ ) with heat generated in the bar uniformly at a rate of  $\dot{e} = 3 \times 10^6 \text{ W/m}^3$ . The left and bottom surfaces maintain a constant temperature of  $200^\circ\text{C}$ . The top and right surfaces are subjected to convection with ambient air temperature of  $100^\circ\text{C}$  and heat transfer coefficient of  $250 \text{ W/m}^2\cdot\text{K}$ . Using a uniform mesh size  $\Delta x = \Delta y = 1 \text{ cm}$  determine (a) the finite difference equations and (b) the nodal temperatures with the Gauss-Seidel iterative method.

FIGURE P5-140

**5-141** A two-dimensional bar has the geometry shown in Fig. P5-141 with specified temperature  $T_A$  on the upper surface and  $T_B$  on the lower surfaces, and insulation on the sides. The thermal conductivity of the upper part of the bar is  $k_A$  while that of the lower part is  $k_B$ . For a grid defined by  $\Delta x = \Delta y = l$ , write the simplest form of the matrix equation,  $AT = C$ , used to find the steady-state temperature field in the cross section of the bar. Identify on the figure the grid nodes where you write the energy balance.

FIGURE P5-141

**5-142** Starting with an energy balance on a disk volume element, derive the one-dimensional transient implicit finite difference equation for a general interior node for  $T(z, t)$  in a cylinder whose side surface is subjected to convection with a convection coefficient of  $h$  and an ambient temperature of  $T_\infty$  for the case of constant thermal conductivity with uniform heat generation.

**5-143** A hot surface at  $120^\circ\text{C}$  is to be cooled by attaching 8 cm long, 0.8 cm in diameter aluminum pin fins ( $k = 237 \text{ W/m}\cdot\text{K}$  and  $\alpha = 97.1 \times 10^{-6} \text{ m}^2/\text{s}$ ) to it with a center-to-center distance of 1.6 cm. The temperature of the surrounding medium is  $15^\circ\text{C}$ , and the heat transfer coefficient on the surfaces is  $35 \text{ W/m}^2\cdot\text{K}$ . Initially, the fins are at a uniform temperature of  $30^\circ\text{C}$ , and at time  $t = 0$ , the temperature of the hot surface is raised to  $120^\circ\text{C}$ . Assuming one-dimensional heat conduction along the fin and taking the nodal spacing to be  $\Delta x = 2 \text{ cm}$  and a time step to be  $\Delta t = 0.5 \text{ s}$ , determine the nodal temperatures after 10 min by using the explicit finite difference method. Also, determine how long it will take for steady conditions to be reached.

FIGURE P5-143

**5-144** Solar radiation incident on a large body of clean water ( $k = 0.61 \text{ W/m}\cdot\text{K}$  and  $\alpha = 0.15 \times 10^{-6} \text{ m}^2/\text{s}$ ) such as a lake, a river, or a pond is mostly absorbed by water, and the amount of absorption varies with depth. For solar radiation incident at a  $45^\circ$  angle on a 1-m-deep large pond whose bottom surface is black (zero reflectivity), for example, 2.8 percent of the solar energy is reflected back to the atmosphere, 37.9 percent is absorbed by the bottom surface, and the remaining 59.3 percent is absorbed by the water body. If the pond is considered

to be four layers of equal thickness (0.25 m in this case), it can be shown that 47.3 percent of the incident solar energy is absorbed by the top layer, 6.1 percent by the upper mid layer, 3.6 percent by the lower mid layer, and 2.4 percent by the bottom layer [for more information see Çengel and Özişik, *Solar Energy*, 33, no. 6 (1984), pp. 581–591]. The radiation absorbed by the water can be treated conveniently as heat generation in the heat transfer analysis of the pond.

Consider a large 1-m-deep pond that is initially at a uniform temperature of 15°C throughout. Solar energy is incident on the pond surface at 45° at an average rate of 500 W/m<sup>2</sup> for a period of 4 h. Assuming no convection currents in the water and using the explicit finite difference method with a mesh size of  $\Delta x = 0.25$  m and a time step of  $\Delta t = 15$  min, determine the temperature distribution in the pond under the most favorable conditions (i.e., no heat losses from the top or bottom surfaces of the pond). The solar energy absorbed by the bottom surface of the pond can be treated as a heat flux to the water at that surface in this case.

**FIGURE P5-144**

**5-145** Reconsider Prob. 5-144. The absorption of solar radiation in that case can be expressed more accurately as a fourth-degree polynomial as

$$\dot{e}(x) = \dot{q}_s(0.859 - 3.415x + 6.704x^2 - 6.339x^3 + 2.278x^4), \text{ W/m}^3$$

where  $\dot{q}_s$  is the solar flux incident on the surface of the pond in W/m<sup>2</sup> and  $x$  is the distance from the free surface of the pond in m. Solve Problem 5-144 using this relation for the absorption of solar radiation.

**5-146** A hot brass plate is having its upper surface cooled by impinging jet of air at temperature of 15°C and convection heat transfer coefficient of 220 W/m<sup>2</sup>·K. The 10-cm-thick brass plate ( $\rho = 8530 \text{ kg/m}^3$ ,  $c_p = 380 \text{ J/kg} \cdot \text{K}$ ,  $k = 110 \text{ W/m} \cdot \text{K}$ , and  $\alpha = 33.9 \times 10^{-6} \text{ m}^2/\text{s}$ ) had a uniform

**FIGURE P5-145**

initial temperature of 650°C, and the lower surface of the plate is insulated. Using a uniform nodal spacing of  $\Delta x = 2.5 \text{ cm}$  determine (a) the explicit finite difference equations, (b) the maximum allowable value of the time step, (c) the temperature at the center plane of the brass plate after 1 minute of cooling, and (d) compare the result in (c) with the approximate analytical solution from Chapter 4.

**5-147** Consider a uranium nuclear fuel element ( $k = 35 \text{ W/m} \cdot \text{K}$ ,  $\rho = 19,070 \text{ kg/m}^3$  and  $c_p = 116 \text{ J/kg} \cdot \text{K}$ ) of radius 10 cm that experiences a volumetric heat generation at a rate of  $4 \times 10^5 \text{ W/m}^3$  because of the nuclear fission reaction. The nuclear fuel element initially at a temperature of 500°C is enclosed inside a cladding made of stainless steel material ( $k = 15 \text{ W/m} \cdot \text{K}$ ,  $\rho = 8055 \text{ kg/m}^3$  and  $c_p = 480 \text{ J/kg} \cdot \text{K}$ ) of thickness 4 cm. The fuel element is cooled by passing pressurized heavy water over the cladding surface. The pressurized water has a bulk temperature of 50°C and the convective heat transfer coefficient is 1000 W/m<sup>2</sup>·K. Assuming one dimensional transient heat conduction in Cartesian coordinates, determine the temperature in the fuel rod and in the cladding after 10, 20 and 30 min. Use implicit finite difference formulation with a uniform mesh size of 2 cm and time step of 1 min.

**FIGURE P5-147**

**5-148** Starting with an energy balance on the volume element, obtain the two-dimensional transient explicit finite difference equation for a general interior node in rectangular

coordinates for  $T(x, y, t)$  for the case of constant thermal conductivity and uniform heat generation.

**5–149** A long steel bar has the cross section shown in Fig. P5–149. The bar is removed from a heat treatment oven at  $T_i = 700^\circ\text{C}$  and placed on the bottom of a tank filled with water at  $10^\circ\text{C}$ . To intensify the heat transfer, the water is vigorously circulated, which creates a virtually constant temperature  $T_s = 10^\circ\text{C}$  on all sides of the bar, except for the bottom side, which is adiabatic. The properties of the bar are  $c_p = 430 \text{ J/kg}\cdot\text{K}$ ,  $k = 40 \text{ W/m}\cdot\text{K}$ , and  $\rho = 8000 \text{ kg/m}^3$ .

- Write the finite difference equations for the unknown temperatures in the grid using the explicit method. Group all constant quantities in one term. Identify dimensionless parameters such as Bi and Fo if applicable.
- Determine the range of time steps for which the explicit scheme is numerically stable.
- For  $\Delta t = 10 \text{ s}$ , determine the temperature field at  $t = 10 \text{ s}$  and  $t = 20 \text{ s}$ . Fill in the table below.

| Node | $T(10 \text{ s})$ | $T(20 \text{ s})$ |
|------|-------------------|-------------------|
| 1    | —                 | —                 |
| 2    | —                 | —                 |
| 3    | —                 | —                 |
| 4    | —                 | —                 |
| 5    | —                 | —                 |
| 6    | —                 | —                 |
| 7    | —                 | —                 |

### Fundamentals of Engineering (FE) Exam Problems

**5–150** The unsteady forward-difference heat conduction for a constant area,  $A$ , pin fin with perimeter,  $p$ , exposed to air whose temperature is  $T_0$  with a convection heat transfer coefficient of  $h$  is

$$T_m^{*+1} = \frac{k}{\rho c_p \Delta x^2} \left[ T_{m-1}^* + T_{m+1}^* + \frac{hp \Delta x^2}{A} T_0 \right] - \left[ 1 - \frac{2k}{\rho c_p \Delta x^2} - \frac{hp}{\rho c_p A} \right] T_m^*$$

In order for this equation to produce a stable solution, the quantity  $\frac{2k}{\rho c_p \Delta x^2} + \frac{hp}{\rho c_p A}$  must be

- (a) negative      (b) zero      (c) positive  
(d) greater than 1      (e) less than 1

**5–151** Air at  $T_0$  acts on top surface of the rectangular solid shown in Fig. P5–151 with a convection heat transfer coefficient of  $h$ . The correct steady-state finite-difference heat conduction equation for node 3 of this solid is

- $T_3 = [(k/2\Delta)(T_2 + T_4 + T_7) + hT_0] / [(k/\Delta) + h]$
- $T_3 = [(k/2\Delta)(T_2 + T_4 + 2T_7) + hT_0] / [(2k/\Delta) + h]$
- $T_3 = [(k/\Delta)(T_2 + T_4) + hT_0] / [(2k/\Delta) + h]$
- $T_3 = [(k/\Delta)(T_2 + T_4 + T_7) + hT_0] / [(k/\Delta) + h]$
- $T_3 = [(k/\Delta)(2T_2 + 2T_4 + T_7) + hT_0] / [(k/\Delta) + h]$

FIGURE P5–151

**5–152** What is the correct unsteady forward-difference heat conduction equation of node 6 of the rectangular solid shown in Fig. P5–152 if its temperature at the previous time ( $\Delta t$ ) is  $T_6^*$ ?

- $T_6^{i+1} = [k\Delta t / (\rho c_p \Delta^2)](T_5^* + T_2^* + T_7^* + T_{10}^*) + [1 - 4k\Delta t / (\rho c_p \Delta^2)]T_6^*$
- $T_6^{i+1} = [k\Delta t / (\rho c_p \Delta^2)](T_5^* + T_2^* + T_7^* + T_{10}^*) + [1 - k\Delta t / (\rho c_p \Delta^2)]T_6^*$
- $T_6^{i+1} = [k\Delta t / (\rho c_p \Delta^2)](T_5^* + T_2^* + T_7^* + T_{10}^*) + [2k\Delta t / (\rho c_p \Delta^2)]T_6^*$
- $T_6^{i+1} = [2k\Delta t / (\rho c_p \Delta^2)](T_5^* + T_2^* + T_7^* + T_{10}^*) + [1 - 2k\Delta t / (\rho c_p \Delta^2)]T_6^*$
- $T_6^{i+1} = [2k\Delta t / (\rho c_p \Delta^2)](T_5^* + T_2^* + T_7^* + T_{10}^*) + [1 - 4k\Delta t / (\rho c_p \Delta^2)]T_6^*$

FIGURE P5–152

**5–153** What is the correct steady-state finite-difference heat conduction equation of node 6 of the rectangular solid shown in Fig. P5–153?

- $T_6 = (T_1 + T_3 + T_9 + T_{11})/2$
- $T_6 = (T_5 + T_7 + T_2 + T_{10})/2$
- $T_6 = (T_1 + T_3 + T_9 + T_{11})/4$
- $T_6 = (T_2 + T_5 + T_7 + T_{10})/4$
- $T_6 = (T_2 + T_5 + T_7 + T_{10})/2$

FIGURE P5–153

**5–154** The height of the cells for a finite-difference solution of the temperature in the rectangular solid shown in Fig. P5–154 is one-half the cell width to improve the accuracy of the solution. The correct steady-state finite-difference heat conduction equation for cell 6 is

- $T_6 = 0.1(T_5 + T_7) + 0.4(T_2 + T_{10})$
- $T_6 = 0.25(T_5 + T_7) + 0.25(T_2 + T_{10})$
- $T_6 = 0.5(T_5 + T_7) + 0.5(T_2 + T_{10})$
- $T_6 = 0.4(T_5 + T_7) + 0.1(T_2 + T_{10})$
- $T_6 = 0.5(T_5 + T_7) + 0.5(T_2 + T_{10})$

FIGURE P5–154

**5–155** The height of the cells for a finite-difference solution of the temperature in the rectangular solid shown in Fig. P5–155 is one-half the cell width to improve the accuracy of the solution. If the left surface is exposed to air at  $T_0$  with a

FIGURE P5–155

heat transfer coefficient of  $h$ , the correct finite-difference heat conduction energy balance for node 5 is

- $2T_1 + 2T_9 + T_6 - T_5 + h\Delta/k(T_0 - T_5) = 0$
- $2T_1 + 2T_9 + T_6 - 2T_5 + h\Delta/k(T_0 - T_5) = 0$
- $2T_1 + 2T_9 + T_6 - 3T_5 + h\Delta/k(T_0 - T_5) = 0$
- $2T_1 + 2T_9 + T_6 - 4T_5 + h\Delta/k(T_0 - T_5) = 0$
- $2T_1 + 2T_9 + T_6 - 5T_5 + h\Delta/k(T_0 - T_5) = 0$

### Design and Essay Problems

**5–156** Write a two-page essay on the finite element method, and explain why it is used in most commercial engineering software packages. Also explain how it compares to the finite difference method.

**5–157** Numerous professional software packages are available in the market for performing heat transfer analysis, and they are widely advertised in professional magazines such as the *Mechanical Engineering* magazine published by the American Society of Mechanical Engineers (ASME). Your company decides to purchase such a software package and asks you to prepare a report on the available packages, their costs, capabilities, ease of use, and compatibility with the available hardware, and other software as well as the reputation of the software company, their history, financial health, customer support, training, and future prospects, among other things. After a preliminary investigation, select the top three packages and prepare a full report on them.

**5–158** Design a defrosting plate to speed up defrosting of flat food items such as frozen steaks and packaged vegetables and evaluate its performance using the finite difference method. Compare your design to the defrosting plates currently available on the market. The plate must perform well, and it must be suitable for purchase and use as a household utensil, durable, easy to clean, easy to manufacture, and affordable. The frozen food is expected to be at an initial temperature of  $-18^\circ\text{C}$  at the beginning of the thawing process and  $0^\circ\text{C}$  at the end with all the ice melted. Specify the material, shape, size, and thickness of the proposed plate. Justify your recommendations by calculations. Take the ambient and surrounding surface temperatures to be  $20^\circ\text{C}$  and the convection heat transfer coefficient to be  $15 \text{ W/m}^2\text{-K}$  in your analysis. For a typical case, determine the defrosting time with and without the plate.

**5–159** Design a fire-resistant safety box whose outer dimensions are  $0.5 \text{ m} \times 0.5 \text{ m} \times 0.5 \text{ m}$  that will protect its combustible contents from fire which may last up to 2 h. Assume the box will be exposed to an environment at an average temperature of  $700^\circ\text{C}$  with a combined heat transfer coefficient of  $70 \text{ W/m}^2\text{-K}$  and the temperature inside the box must be below  $150^\circ\text{C}$  at the end of 2 h. The cavity of the box must be as large as possible while meeting the design constraints, and the insulation material selected must withstand the high temperatures to which it will be exposed. Cost, durability, and strength are also important considerations in the selection of insulation materials.

# FUNDAMENTALS OF CONVECTION

**S**o far, we have considered *conduction*, which is the mechanism of heat transfer through a solid or a quiescent fluid. We now consider *convection*, which is the mechanism of heat transfer through a fluid in the presence of bulk fluid motion.

Convection is classified as *natural* (or *free*) and *forced convection*, depending on how the fluid motion is initiated. In forced convection, the fluid is forced to flow over a surface or in a pipe by external means such as a pump or a fan. In natural convection, any fluid motion is caused by natural means such as the buoyancy effect, which manifests itself as the rise of warmer fluid and the fall of the cooler fluid. Convection is also classified as *external* and *internal*, depending on whether the fluid is forced to flow over a surface or in a pipe.

We start this chapter with a general physical description of the convection mechanism. We then discuss the *velocity* and *thermal boundary layers*, and *laminar* and *turbulent flows*. We continue with the discussion of the dimensionless *Reynolds*, *Prandtl*, and *Nusselt numbers*, and their physical significance. Next we derive the *convection equations* on the basis of mass, momentum, and energy conservation, and obtain solutions for *flow over a flat plate*. We then nondimensionalize the convection equations, and obtain functional forms of friction and convection coefficients. Finally, we present analogies between momentum and heat transfer.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Understand the physical mechanism of convection, and its classification,
- Visualize the development of velocity and thermal boundary layers during flow over surfaces,
- Gain a working knowledge of the dimensionless Reynolds, Prandtl, and Nusselt numbers,
- Distinguish between laminar and turbulent flows, and gain an understanding of the mechanisms of momentum and heat transfer in turbulent flow,
- Derive the differential equations that govern convection on the basis of mass, momentum, and energy balances, and solve these equations for some simple cases such as laminar flow over a flat plate,
- Nondimensionalize the convection equations and obtain the functional forms of friction and heat transfer coefficients, and
- Use analogies between momentum and heat transfer, and determine heat transfer coefficient from knowledge of friction coefficient.

**FIGURE 6-1**

Heat transfer from a hot surface to the surrounding fluid by convection and conduction.

## 6-1 ▪ PHYSICAL MECHANISM OF CONVECTION

We mentioned in Chapter 1 that there are three basic mechanisms of heat transfer: conduction, convection, and radiation. Conduction and convection are similar in that both mechanisms require the presence of a material medium. But they are different in that convection requires the presence of fluid motion.

Heat transfer through a solid is always by conduction, since the molecules of a solid remain at relatively fixed positions. Heat transfer through a liquid or gas, however, can be by conduction or convection, depending on the presence of any bulk fluid motion. Heat transfer through a fluid is by convection in the presence of bulk fluid motion and by conduction in the absence of it. Therefore, conduction in a fluid can be viewed as the limiting case of convection, corresponding to the case of quiescent fluid (Fig. 6-1).

Convection heat transfer is complicated by the fact that it involves fluid motion as well as heat conduction. The fluid motion enhances heat transfer, since it brings warmer and cooler chunks of fluid into contact, initiating higher rates of conduction at a greater number of sites in a fluid. Therefore, the rate of heat transfer through a fluid is much higher by convection than it is by conduction. In fact, the higher the fluid velocity, the higher the rate of heat transfer.

To clarify this point further, consider steady heat transfer through a fluid contained between two parallel plates maintained at different temperatures, as shown in Figure 6-2. The temperatures of the fluid and the plate are the same at the points of contact because of the continuity of temperature. Assuming no fluid motion, the energy of the hotter fluid molecules near the hot plate is transferred to the adjacent cooler fluid molecules. This energy is then transferred to the next layer of the cooler fluid molecules. This energy is then transferred to the next layer of the cooler fluid, and so on, until it is finally transferred to the other plate. This is what happens during conduction through a fluid. Now let us use a syringe to draw some fluid near the hot plate and inject it next to the cold plate repeatedly. You can imagine that this will speed up the heat transfer process considerably, since some energy is carried to the other side as a result of fluid motion.

Consider the cooling of a hot block with a fan blowing air over its top surface. We know that heat is transferred from the hot block to the surrounding cooler air, and the block eventually cools. We also know that the block cools faster if the fan is switched to a higher speed. Replacing air by water enhances the convection heat transfer even more.

Experience shows that convection heat transfer strongly depends on the fluid properties *dynamic viscosity*  $\mu$ , *thermal conductivity*  $k$ , *density*  $\rho$ , and *specific heat*  $c_p$ , as well as the *fluid velocity*  $V$ . It also depends on the *geometry* and the *roughness* of the solid surface, in addition to the *type of fluid flow* (such as being streamlined or turbulent). Thus, we expect the convection heat transfer relations to be rather complex because of the dependence of convection on so many variables. This is not surprising, since convection is the most complex mechanism of heat transfer.

Despite the complexity of convection, the rate of convection heat transfer is observed to be proportional to the temperature difference and is conveniently expressed by **Newton's law of cooling** as

$$\dot{q}_{\text{conv}} = h(T_s - T_\infty) \quad (\text{W/m}^2) \quad (6-1)$$

**FIGURE 6-2**

Heat transfer through a fluid sandwiched between two parallel plates.

or

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty) \quad (\text{W}) \quad (6-2)$$

where

$h$  = convection heat transfer coefficient,  $\text{W/m}^2\cdot\text{K}$

$A_s$  = heat transfer surface area,  $\text{m}^2$

$T_s$  = temperature of the surface,  $^\circ\text{C}$

$T_\infty$  = temperature of the fluid sufficiently far from the surface,  $^\circ\text{C}$

Judging from its units, the **convection heat transfer coefficient**  $h$  can be defined as *the rate of heat transfer between a solid surface and a fluid per unit surface area per unit temperature difference*.

You should not be deceived by the simple appearance of this relation, because the convection heat transfer coefficient  $h$  depends on the several of the mentioned variables, and thus is difficult to determine.

Fluid flow is often confined by solid surfaces, and it is important to understand how the presence of solid surfaces affects fluid flow. Consider the flow of a fluid in a stationary pipe or over a solid surface that is nonporous (i.e., impermeable to the fluid). All experimental observations indicate that a fluid in motion comes to a complete stop at the surface and assumes a zero velocity relative to the surface. That is, a fluid in direct contact with a solid “sticks” to the surface due to viscous effects, and there is no slip. This is known as the **no-slip condition**.

The photo in Fig. 6–3 obtained from a video clip clearly shows the evolution of a velocity gradient as a result of the fluid sticking to the surface of a blunt nose. The layer that sticks to the surface slows the adjacent fluid layer because of viscous forces between the fluid layers, which slows the next layer, and so on. Therefore, the no-slip condition is responsible for the development of the velocity profile. The flow region adjacent to the wall in which the viscous effects (and thus the velocity gradients) are significant is called the **boundary layer**. The fluid property responsible for the no-slip condition and the development of the boundary layer is *viscosity* and is discussed briefly in Section 6–2.

A fluid layer adjacent to a moving surface has the same velocity as the surface. A consequence of the no-slip condition is that all velocity profiles must have zero values with respect to the surface at the points of contact between a fluid and a solid surface (Fig. 6–4). Another consequence of the no-slip condition is the **surface drag**, which is the force a fluid exerts on a surface in the flow direction.

An implication of the no-slip condition is that heat transfer from the solid surface to the fluid layer adjacent to the surface is by *pure conduction*, since the fluid layer is motionless, and can be expressed as

$$\dot{q}_{\text{conv}} = \dot{q}_{\text{cond}} = -k_{\text{fluid}} \frac{\partial T}{\partial y} \Big|_{y=0} \quad (\text{W/m}^2) \quad (6-3)$$

where  $T$  represents the temperature distribution in the fluid and  $(\partial T / \partial y)_{y=0}$  is the *temperature gradient* at the surface. Heat is then *convected away* from the surface as a result of fluid motion. Note that convection heat transfer from a solid surface to a fluid is merely the conduction heat transfer from the solid surface to the fluid layer adjacent to the surface. Therefore, we can equate Eqs. 6–1 and 6–3 for the heat flux to obtain

$$h = \frac{-k_{\text{fluid}}(\partial T / \partial y)_{y=0}}{T_s - T_\infty} \quad (\text{W/m}^2\cdot\text{K}) \quad (6-4)$$

**Wilhelm Nusselt** (1882–1957), was a German engineer, born in Nuremberg, Germany. He studied machinery at the Technical Universities of Berlin-Charlottenburg and Munchen and conducted advanced studies in mathematics and physics. His doctoral thesis was on the “Conductivity of Insulating Materials” which he completed in 1907. In 1915, Nusselt published his pioneering paper: The Basic Laws of Heat Transfer, in which he first proposed the dimensionless groups now known as the principal parameters in the similarity theory of heat transfer. His other famous works were concerned with the film condensation of steam on vertical surfaces, the combustion of pulverized coal and the analogy between heat and mass transfer in evaporation. Among his well known mathematical works are the solutions for laminar heat transfer in the entrance region of tubes and for heat exchange in cross-flow, and the basic theory of regenerators.

for the determination of the *convection heat transfer coefficient* when the temperature distribution within the fluid is known.

The convection heat transfer coefficient, in general, varies along the flow (or  $x$ -) direction. The *average* or *mean* convection heat transfer coefficient for a surface in such cases is determined by properly averaging the *local* convection heat transfer coefficients over the entire surface.

## Nusselt Number

In convection studies, it is common practice to nondimensionalize the governing equations and combine the variables, which group together into *dimensionless numbers* in order to reduce the number of total variables. It is also common practice to nondimensionalize the heat transfer coefficient  $h$  with the Nusselt number, defined as

$$\text{Nu} = \frac{hL_c}{k} \quad (6-5)$$

where  $k$  is the thermal conductivity of the fluid and  $L_c$  is the *characteristic length*. The Nusselt number is named after Wilhelm Nusselt (Fig. 6–5), who made significant contributions to convective heat transfer in the first half of the twentieth century, and it is viewed as the *dimensionless convection heat transfer coefficient*.

To understand the physical significance of the Nusselt number, consider a fluid layer of thickness  $L$  and temperature difference  $\Delta T = T_2 - T_1$ , as shown in Fig. 6–6. Heat transfer through the fluid layer is by *convection* when the fluid involves some motion and by *conduction* when the fluid layer is motionless. Heat flux (the rate of heat transfer per unit surface area) in either case is

$$\dot{q}_{\text{conv}} = h\Delta T \quad (6-6)$$

and

$$\dot{q}_{\text{cond}} = k \frac{\Delta T}{L} \quad (6-7)$$

Taking their ratio gives

$$\frac{\dot{q}_{\text{conv}}}{\dot{q}_{\text{cond}}} = \frac{h\Delta T}{k\Delta T/L} = \frac{hL}{k} = \text{Nu} \quad (6-8)$$

which is the Nusselt number. Therefore, the Nusselt number represents the enhancement of heat transfer through a fluid layer as a result of convection relative to conduction across the same fluid layer. The larger the Nusselt number, the more effective the convection. A Nusselt number of  $\text{Nu} = 1$  for a fluid layer represents heat transfer across the layer by pure conduction.

We use forced convection in daily life more often than you might think (Fig. 6–7). We resort to forced convection whenever we want to increase the rate of heat transfer from a hot object. For example, we turn on the fan on hot summer days to help our body cool more effectively. The higher the fan speed, the better we feel. We *stir* our soup and *blow* on a hot slice of pizza to make them cool faster. The air on windy winter days feels much colder than it actually is. The simplest solution to heating problems in electronics packaging is to use a large enough fan.

**EXAMPLE 6-1 Heat Transfer Calculation from Temperature Profile**

During the flow of air at  $T_\infty = 20^\circ\text{C}$  over a plate surface maintained at a constant temperature of  $T_s = 160^\circ\text{C}$ , the dimensionless temperature profile within the air layer over the plate is determined to be

$$\frac{T(y) - T_\infty}{T_s - T_\infty} = e^{-ay}$$

where  $a = 3200 \text{ m}^{-1}$  and  $y$  is the vertical distance measured from the plate surface in m (Fig. 6-8). Determine the heat flux on the plate surface and the convection heat transfer coefficient.

**SOLUTION** Airflow over a flat plate has a given temperature profile. The heat flux on the plate surface and the convection heat transfer coefficient are to be determined.

**Assumptions** 1 The given nondimensional temperature profile is representative of the variation of temperature over the entire plate. 2 Heat transfer by radiation is negligible.

**Properties** The thermal conductivity of air at the film temperature of  $T_f = (T_s + T_\infty)/2 = (160^\circ\text{C} + 20^\circ\text{C})/2 = 90^\circ\text{C}$  is  $k = 0.03024 \text{ W/m}\cdot\text{K}$  (Table A-15).

**Analysis** Noting that heat transfer from the plate to air at the surface is by conduction, heat flux from the solid surface to the fluid layer adjacent to the surface is determined from

$$\dot{q} = \dot{q}_{\text{cond}} = -k_{\text{fluid}} \frac{\partial T}{\partial y} \Big|_{y=0}$$

where the temperature gradient at the plate surface is

$$\begin{aligned} \left. \frac{\partial T}{\partial y} \right|_{y=0} &= (T_s - T_\infty)a[e^{-ay}]_{y=0} = (T_s - T_\infty)(-a) \\ &= (160^\circ\text{C} - 20^\circ\text{C})(-3200 \text{ m}^{-1}) = -4.48 \times 10^5 \text{ }^\circ\text{C/m} \end{aligned}$$

Substituting, the heat flux is determined to be

$$\dot{q} = -(0.03024 \text{ W/m}\cdot\text{K})(-4.48 \times 10^5 \text{ }^\circ\text{C/m}) = 1.35 \times 10^4 \text{ W/m}^2$$

Then the convection heat transfer coefficient becomes

$$\begin{aligned} h &= \frac{-k_{\text{fluid}} (\partial T / \partial y)_{y=0}}{T_s - T_\infty} \\ &= \frac{-(0.03024 \text{ W/m}\cdot\text{K})(-4.48 \times 10^5 \text{ }^\circ\text{C/m})}{(160^\circ\text{C} - 20^\circ\text{C})} = 96.8 \text{ W/m}^2\cdot\text{K} \end{aligned}$$

**Discussion** The convection heat transfer coefficient could also be determined from Newton's law of cooling,  $\dot{q} = h(T_s - T_\infty)$ .

**FIGURE 6-6**

Heat transfer through a fluid layer of thickness  $L$  and temperature difference  $\Delta T$ .

**FIGURE 6-7**

We resort to forced convection whenever we need to increase the rate of heat transfer.

## 6–2 ▪ CLASSIFICATION OF FLUID FLOWS

Convection heat transfer is closely tied with fluid mechanics, which is the science that deals with the behavior of fluids at rest or in motion, and the interaction of fluids with solids or other fluids at the boundaries. There is a wide variety of fluid flow problems encountered in practice, and it is usually convenient to classify them on the basis of some common characteristics to make it feasible to study them in groups. There are many ways to classify fluid flow problems, and here we present some general categories.

### Viscous versus Inviscid Regions of Flow

When two fluid layers move relative to each other, a friction force develops between them and the slower layer tries to slow down the faster layer. This internal resistance to flow is quantified by the fluid property *viscosity*, which is a measure of internal stickiness of the fluid. Viscosity is caused by cohesive forces between the molecules in liquids and by molecular collisions in gases. There is no fluid with zero viscosity, and thus all fluid flows involve viscous effects to some degree. Flows in which the frictional effects are significant are called **viscous flows**. However, in many flows of practical interest, there are *regions* (typically regions not close to solid surfaces) where viscous forces are negligibly small compared to inertial or pressure forces. Neglecting the viscous terms in such **inviscid flow regions** greatly simplifies the analysis without much loss in accuracy.

The development of viscous and inviscid regions of flow as a result of inserting a flat plate parallel into a fluid stream of uniform velocity is shown in Fig. 6–9. The fluid sticks to the plate on both sides because of the no-slip condition, and the thin boundary layer in which the viscous effects are significant near the plate surface is the *viscous flow region*. The region of flow on both sides away from the plate and unaffected by the presence of the plate is the *inviscid flow region*.

### Internal versus External Flow

A fluid flow is classified as being internal or external, depending on whether the fluid is forced to flow in a confined channel or over a surface. The flow of an unbounded fluid over a surface such as a plate, a wire, or a pipe is **external flow**. The flow in a pipe or duct is **internal flow** if the fluid is completely bounded by solid surfaces. Water flow in a pipe, for example, is internal flow, and airflow over a ball or over an exposed pipe during a windy day is external flow (Fig. 6–10). The flow of liquids in a duct is called *open-channel flow* if the duct is only partially filled with the liquid and there is a free surface. The flows of water in rivers and irrigation ditches are examples of such flows.

Internal flows are dominated by the influence of viscosity throughout the flow field. In external flows the viscous effects are limited to boundary layers near solid surfaces and to wake regions downstream of bodies.

### Compressible versus Incompressible Flow

A flow is classified as being *compressible* or *incompressible*, depending on the level of variation of density during flow. Incompressibility is an approximation, and a flow is said to be **incompressible** if the density remains

**FIGURE 6–9**

The flow of an originally uniform fluid stream over a flat plate, and the regions of viscous flow (next to the plate on both sides) and inviscid flow (away from the plate).

*Fundamentals of Boundary Layers, National Committee from Fluid Mechanics Films, © Education Development Center.*

External flow over a tennis ball, and the turbulent wake region behind.

*Courtesy NASA and Cislunar Aerospace, Inc.*

nearly constant throughout. Therefore, the volume of every portion of fluid remains unchanged over the course of its motion when the flow (or the fluid) is incompressible.

The densities of liquids are essentially constant, and thus the flow of liquids is typically incompressible. Therefore, liquids are usually referred to as *incompressible substances*. A pressure of 210 atm, for example, causes the density of liquid water at 1 atm to change by just 1 percent. Gases, on the other hand, are highly compressible. A pressure change of just 0.01 atm, for example, causes a change of 1 percent in the density of atmospheric air.

Liquid flows are incompressible to a high level of accuracy, but the level of variation in density in gas flows and the consequent level of approximation made when modeling gas flows as incompressible depends on the Mach number defined as  $Ma = V/c$ , where  $c$  is the **speed of sound** whose value is 346 m/s in air at room temperature at sea level. Gas flows can often be approximated as incompressible if the density changes are under about 5 percent, which is usually the case when  $Ma < 0.3$ . Therefore, the compressibility effects of air can be neglected at speeds under about 100 m/s. Note that the flow of a gas is not necessarily a compressible flow.

Small density changes of liquids corresponding to large pressure changes can still have important consequences. The irritating “water hammer” in a water pipe, for example, is caused by the vibrations of the pipe generated by the reflection of pressure waves following the sudden closing of the valves.

## Laminar versus Turbulent Flow

Some flows are smooth and orderly while others are rather chaotic. The highly ordered fluid motion characterized by smooth layers of fluid is called **laminar**. The word *laminar* comes from the movement of adjacent fluid particles together in “laminates.” The flow of high-viscosity fluids such as oils at low velocities is typically laminar. The highly disordered fluid motion that typically occurs at high velocities and is characterized by velocity fluctuations is called **turbulent** (Fig. 6–11). The flow of low-viscosity fluids such as air at high velocities is typically turbulent. The flow regime greatly influences the required power for pumping. A flow that alternates between being laminar and turbulent is called **transitional**.

## Natural (or Unforced) versus Forced Flow

A fluid flow is said to be natural or forced, depending on how the fluid motion is initiated. In **forced flow**, a fluid is forced to flow over a surface or in a pipe by external means such as a pump or a fan. In **natural flows**, any fluid motion is due to natural means such as the buoyancy effect, which manifests itself as the rise of the warmer (and thus lighter) fluid and the fall of cooler (and thus denser) fluid (Fig. 6–12). In solar hot-water systems, for example, the thermosiphoning effect is commonly used to replace pumps by placing the water tank sufficiently above the solar collectors.

## Steady versus Unsteady Flow

The terms *steady* and *uniform* are used frequently in engineering, and thus it is important to have a clear understanding of their meanings. The term **steady** implies *no change at a point with time*. The opposite of steady is **unsteady**.

**FIGURE 6–11**

and turbulent flows.

**FIGURE 6–12**

In this schlieren image of a girl, the rise of lighter, warmer air adjacent to her body indicates that humans and warm-blooded animals are surrounded by thermal plumes of rising warm air.

G. S. Settles, *Gas Dynamics Lab, Penn State University*. Used by permission.

The term **uniform** implies *no change with location* over a specified region. These meanings are consistent with their everyday use (steady girlfriend, uniform distribution, etc.).

The terms *unsteady* and *transient* are often used interchangeably, but these terms are not synonyms. In fluid mechanics, *unsteady* is the most general term that applies to any flow that is not steady, but **transient** is typically used for developing flows. When a rocket engine is fired up, for example, there are transient effects (the pressure builds up inside the rocket engine, the flow accelerates, etc.) until the engine settles down and operates steadily. The term **periodic** refers to the kind of unsteady flow in which the flow oscillates about a steady mean.

Many devices such as turbines, compressors, boilers, condensers, and heat exchangers operate for long periods of time under the same conditions, and they are classified as *steady-flow devices*. (Note that the flow field near the rotating blades of a turbomachine is of course unsteady, but we consider the overall flow field rather than the details at some localities when we classify devices.) During steady flow, the fluid properties can change from point to point within a device, but at any fixed point they remain constant. Therefore, the volume, the mass, and the total energy content of a steady-flow device or flow section remain constant in steady operation.

Steady-flow conditions can be closely approximated by devices that are intended for continuous operation such as turbines, pumps, boilers, condensers, and heat exchangers of power plants or refrigeration systems. Some cyclic devices, such as reciprocating engines or compressors, do not satisfy the steady-flow conditions since the flow at the inlets and the exits is pulsating and not steady. However, the fluid properties vary with time in a periodic manner, and the flow through these devices can still be analyzed as a steady-flow process by using time-averaged values for the properties.

## One-, Two-, and Three-Dimensional Flows

A flow field is best characterized by the velocity distribution, and thus a flow is said to be one-, two-, or three-dimensional if the flow velocity varies in one, two, or three primary dimensions, respectively. A typical fluid flow involves a three-dimensional geometry, and the velocity may vary in all three dimensions, rendering the flow three-dimensional [ $\vec{V}(x, y, z)$  in rectangular or  $\vec{V}(r, \theta, z)$  in cylindrical coordinates]. However, the variation of velocity in certain directions can be small relative to the variation in other directions and can be ignored with negligible error. In such cases, the flow can be modeled conveniently as being one- or two-dimensional, which is easier to analyze.

Consider steady flow of a fluid through a circular pipe attached to a large tank. The fluid velocity everywhere on the pipe surface is zero because of the no-slip condition, and the flow is two-dimensional in the entrance region of the pipe since the velocity changes in both the  $r$ - and  $z$ -directions. The velocity profile develops fully and remains unchanged after some distance from the inlet (about 10 pipe diameters in turbulent flow, and less in laminar pipe flow, as in Fig. 6–13), and the flow in this region is said to be *fully developed*. The fully developed flow in a circular pipe is *one-dimensional* since the velocity varies in the radial  $r$ -direction but not in the angular  $\theta$ - or axial  $z$ -directions, as shown in Fig. 6–13. That is, the velocity profile is the same at any axial  $z$ -location, and it is symmetric about the axis of the pipe.

**FIGURE 6–13**

The development of the velocity profile in a circular pipe.  $V = V(r, z)$  and thus the flow is two-dimensional in the entrance region, and becomes one-dimensional downstream when the velocity profile fully develops and remains unchanged in the flow direction,  $V = V(r)$ .

Note that the dimensionality of the flow also depends on the choice of coordinate system and its orientation. The pipe flow discussed, for example, is one-dimensional in cylindrical coordinates, but two-dimensional in Cartesian coordinates—illustrating the importance of choosing the most appropriate coordinate system. Also note that even in this simple flow, the velocity cannot be uniform across the cross section of the pipe because of the no-slip condition. However, at a well-rounded entrance to the pipe, the velocity profile may be approximated as being nearly uniform across the pipe, since the velocity is nearly constant at all radii except very close to the pipe wall.

### 6–3 • VELOCITY BOUNDARY LAYER

Consider the parallel flow of a fluid over a *flat plate*, as shown in Fig. 6–14. Surfaces that are slightly contoured such as turbine blades can also be approximated as flat plates with reasonable accuracy. The  $x$ -coordinate is measured along the plate surface from the *leading edge* of the plate in the direction of the flow, and  $y$  is measured from the surface in the normal direction. The fluid approaches the plate in the  $x$ -direction with a uniform velocity  $V$ , which is practically identical to the free-stream velocity over the plate away from the surface (this would not be the case for cross flow over blunt bodies such as a cylinder).

For the sake of discussion, we can consider the fluid to consist of adjacent layers piled on top of each other. The velocity of the particles in the first fluid

**FIGURE 6–14**

The development of the boundary layer for flow over a flat plate, and the different flow regimes.

Courtesy of University of Delaware.

**FIGURE 6-15**

The development of a boundary layer on a surface is due to the no-slip condition and friction.

layer adjacent to the plate becomes zero because of the no-slip condition. This motionless layer slows down the particles of the neighboring fluid layer as a result of friction between the particles of these two adjoining fluid layers at different velocities. This fluid layer then slows down the molecules of the next layer, and so on. Thus, the presence of the plate is felt up to some normal distance  $\delta$  from the plate beyond which the free-stream velocity remains essentially unchanged. As a result, the  $x$ -component of the fluid velocity,  $u$ , varies from 0 at  $y = 0$  to nearly  $V$  at  $y = \delta$  (Fig. 6-15).

The region of the flow above the plate bounded by  $\delta$  in which the effects of the viscous shearing forces caused by fluid viscosity are felt is called the **velocity boundary layer**. The *boundary layer thickness*,  $\delta$ , is typically defined as the distance  $y$  from the surface at which  $u = 0.99V$ .

The hypothetical line of  $u = 0.99V$  divides the flow over a plate into two regions: the **boundary layer region**, in which the viscous effects and the velocity changes are significant, and the **irrotational flow region**, in which the frictional effects are negligible and the velocity remains essentially constant.

## Wall Shear Stress

Consider the flow of a fluid over the surface of a plate. The fluid layer in contact with the surface tries to drag the plate along via friction, exerting a *friction force* on it. Likewise, a faster fluid layer tries to drag the adjacent slower layer and exert a friction force because of the friction between the two layers. Friction force per unit area is called **shear stress**, and is denoted by  $\tau$ . Experimental studies indicate that the shear stress for most fluids is proportional to the *velocity gradient*, and the shear stress at the wall surface is expressed as

$$\tau_w = \mu \left. \frac{\partial u}{\partial y} \right|_{y=0} \quad (\text{N/m}^2) \quad (6-9)$$

where the constant of proportionality  $\mu$  is the **dynamic viscosity** of the fluid, whose unit is kg/m·s (or equivalently, N·s/m<sup>2</sup>, or Pa·s, or poise = 0.1 Pa·s).

The fluids that obey the linear relationship above are called **Newtonian fluids**, after Sir Isaac Newton who expressed it first in 1687 (Fig. 1-36). Most common fluids such as water, air, gasoline, and oils are Newtonian fluids. Blood and liquid plastics are examples of non-Newtonian fluids. In this text we consider Newtonian fluids only.

In fluid flow and heat transfer studies, the ratio of dynamic viscosity to density appears frequently. For convenience, this ratio is given the name **kinematic viscosity**  $\nu$  and is expressed as  $\nu = \mu/\rho$ . Two common units of kinematic viscosity are m<sup>2</sup>/s and stoke (1 stoke = 1 cm<sup>2</sup>/s = 0.0001 m<sup>2</sup>/s).

The viscosity of a fluid is a measure of its *resistance to deformation*, and it is a strong function of temperature. The viscosities of liquids *decrease* with temperature, whereas the viscosities of gases *increase* with temperature (Fig. 6-16). The viscosities of some fluids at 20°C are listed in Table 6-1. Note that the viscosities of different fluids differ by several orders of magnitude.

**FIGURE 6-16**

The viscosity of liquids decreases and the viscosity of gases increases with temperature.

The determination of the wall shear stress  $\tau_w$  from Eq. 6–9 is not practical since it requires a knowledge of the flow velocity profile. A more practical approach in external flow is to relate  $\tau_w$  to the upstream velocity  $V$  as

$$\tau_w = C_f \frac{\rho V^2}{2} \quad (\text{N/m}^2) \quad (6-10)$$

where  $C_f$  is the dimensionless **friction coefficient** or **skin friction coefficient**, whose value in most cases is determined experimentally, and  $\rho$  is the density of the fluid. Note that the friction coefficient, in general, varies with location along the surface. Once the average friction coefficient over a given surface is available, the friction force over the entire surface is determined from

$$F_f = C_f A_s \frac{\rho V^2}{2} \quad (\text{N}) \quad (6-11)$$

where  $A_s$  is the surface area.

The friction coefficient is an important parameter in heat transfer studies since it is directly related to the heat transfer coefficient and the power requirements of the pump or fan.

## 6–4 • THERMAL BOUNDARY LAYER

We have seen that a velocity boundary layer develops when a fluid flows over a surface as a result of the fluid layer adjacent to the surface assuming the surface velocity (i.e., zero velocity relative to the surface). Also, we defined the velocity boundary layer as the region in which the fluid velocity varies from zero to  $0.99V$ . Likewise, a *thermal boundary layer* develops when a fluid at a specified temperature flows over a surface that is at a different temperature, as shown in Fig. 6–17.

Consider the flow of a fluid at a uniform temperature of  $T_\infty$  over an isothermal flat plate at temperature  $T_s$ . The fluid particles in the layer adjacent to the surface reach thermal equilibrium with the plate and assume the surface temperature  $T_s$ . These fluid particles then exchange energy with the particles in the adjoining-fluid layer, and so on. As a result, a temperature profile develops in the flow field that ranges from  $T_s$  at the surface to  $T_\infty$  sufficiently far from the surface. The flow region over the surface in which the temperature variation in the direction normal to the surface is significant is the **thermal boundary layer**. The *thickness* of the thermal boundary layer  $\delta_t$  at any location along the surface is defined as *the distance from the surface at which the temperature difference  $T - T_s$  equals  $0.99(T_\infty - T_s)$* . Note that for the special case of  $T_s = 0$ , we have  $T = 0.99T_\infty$  at the outer edge of the thermal boundary layer, which is analogous to  $u = 0.99V$  for the velocity boundary layer.

The thickness of the thermal boundary layer increases in the flow direction, since the effects of heat transfer are felt at greater distances from the surface further down stream.

The convection heat transfer rate anywhere along the surface is directly related to the temperature gradient at that location. Therefore, the shape of the temperature profile in the thermal boundary layer dictates the convection heat transfer between a solid surface and the fluid flowing over it. In flow over a heated (or cooled) surface, both velocity and thermal boundary layers develop

TABLE 6–1

Dynamic viscosities of some fluids at 1 atm and 20°C (unless otherwise stated)

| Fluid          | Dynamic Viscosity $\mu$ , kg/m·s |
|----------------|----------------------------------|
| Glycerin:      |                                  |
| −20°C          | 134.0                            |
| 0°C            | 10.5                             |
| 20°C           | 1.52                             |

FIGURE 6–17

Thermal boundary layer on a flat plate (the fluid is hotter than the plate surface).

**FIGURE 6–18**

**Ludwig Prandtl** (1875–1953), was a German Physicist famous for his work in aeronautics, born in Freising, Bavaria. His discovery in 1904 of the Boundary Layer which adjoins the surface of a body moving in a fluid led to an understanding of skin friction drag and of the way in which streamlining reduces the drag of airplane wings and other moving bodies. Prandtl's work and decisive advances in boundary layer and wing theories became the basic material of aeronautics. He also made important contributions to the theories of supersonic flow and of turbulence, and contributed much to the development of wind tunnels and other aerodynamic equipment. The dimensionless **Prandtl number** was named after him.

Courtesy DLR-Archive.

**TABLE 6–2**

Typical ranges of Prandtl numbers for common fluids

| Fluid                | Pr           |
|----------------------|--------------|
| Liquid metals        | 0.004–0.030  |
| Gases                | 0.7–1.0      |
| Water                | 1.7–13.7     |
| Light organic fluids | 5–50         |
| Oils                 | 50–100,000   |
| Glycerin             | 2000–100,000 |

simultaneously. Noting that the fluid velocity has a strong influence on the temperature profile, the development of the velocity boundary layer relative to the thermal boundary layer will have a strong effect on the convection heat transfer.

## Prandtl Number

The relative thickness of the velocity and the thermal boundary layers is best described by the *dimensionless* parameter **Prandtl number**, defined as

$$\text{Pr} = \frac{\text{Molecular diffusivity of momentum}}{\text{Molecular diffusivity of heat}} = \frac{v}{\alpha} = \frac{\mu c_p}{k} \quad (6-12)$$

It is named after Ludwig Prandtl (Fig. 6–18), who introduced the concept of boundary layer in 1904 and made significant contributions to boundary layer theory. The Prandtl numbers of fluids range from less than 0.01 for liquid metals to more than 100,000 for heavy oils (Table 6–2). Note that the Prandtl number is in the order of 10 for water.

The Prandtl numbers of gases are about 1, which indicates that both momentum and heat dissipate through the fluid at about the same rate. Heat diffuses very quickly in liquid metals ( $\text{Pr} \ll 1$ ) and very slowly in oils ( $\text{Pr} \gg 1$ ) relative to momentum. Consequently the thermal boundary layer is much thicker for liquid metals and much thinner for oils relative to the velocity boundary layer.

Liquid metals are a special class of fluids with very low Prandtl numbers (Table 6–2). The very low Prandtl number is due to the high thermal conductivity of these fluids, since the specific heat and viscosity of liquid metals are very comparable to other common fluids. Considerable interest has been placed on liquid metals as coolants in applications where large amounts of heat must be removed from a relatively small space, as in a nuclear reactor. Liquid metals, aside from having high thermal conductivity values, have high thermal capacity, low vapor pressure, and low melting point. They remain in the liquid state at higher temperatures than conventional fluids. This makes them more attractive for use in compact heat-exchangers. However, liquid metals are corrosive in nature and their contact with air or water may result in violent action, and suitable measures for handling them have been developed.

## 6–5 • LAMINAR AND TURBULENT FLOWS

If you have been around smokers, you probably noticed that the cigarette smoke rises in a smooth plume for the first few centimeters and then starts fluctuating randomly in all directions as it continues its rise. Other plumes behave similarly (Fig. 6–19). Likewise, a careful inspection of flow in a pipe reveals that the fluid flow is streamlined at low velocities but turns chaotic as the velocity is increased above a critical value, as shown in Figure 6–20. The flow regime in the first case is said to be **laminar**, characterized by *smooth streamlines* and *highly-ordered motion*, and **turbulent** in the second case, where it is characterized by *velocity fluctuations* and *highly-disordered motion*. The **transition** from laminar to turbulent flow does not occur suddenly; rather, it occurs over some region in which the flow fluctuates between laminar and turbulent flows before it becomes fully turbulent. Most flows encountered in practice are turbulent. Laminar flow is encountered when highly viscous fluids such as oils flow in small pipes or narrow passages.

We can verify the existence of these laminar, transitional, and turbulent flow regimes by injecting some dye streak into the flow in a glass tube, as the British scientist Osborn Reynolds (Fig. 6–21) did over a century ago. We observe that the dye streak forms a *straight and smooth line* at low velocities when the flow is laminar (we may see some blurring because of molecular diffusion), has *bursts of fluctuations* in the transitional regime, and *zigzags rapidly and randomly* when the flow becomes fully turbulent. These zigzags and the dispersion of the dye are indicative of the fluctuations in the main flow and the rapid mixing of fluid particles from adjacent layers.

Typical average velocity profiles in laminar and turbulent flow are also given in Fig. 6–14. Note that the velocity profile in turbulent flow is much fuller than that in laminar flow, with a sharp drop near the surface. The turbulent boundary layer can be considered to consist of four regions, characterized by the distance from the wall. The very thin layer next to the wall where viscous effects are dominant is the **viscous sublayer**. The velocity profile in this layer is very nearly *linear*, and the flow is streamlined. Next to the viscous sublayer is the **buffer layer**, in which turbulent effects are becoming significant, but the flow is still dominated by viscous effects. Above the buffer layer is the **overlap layer**, in which the turbulent effects are much more significant, but still not dominant. Above that is the **turbulent layer** in which turbulent effects dominate over viscous effects.

The *intense mixing* of the fluid in turbulent flow as a result of rapid fluctuations enhances heat and momentum transfer between fluid particles, which increases the friction force on the surface and the convection heat transfer rate. It also causes the boundary layer to enlarge. Both the friction and heat transfer coefficients reach maximum values when the flow becomes *fully turbulent*. So it will come as no surprise that a special effort is made in the design of heat transfer coefficients associated with turbulent flow. The enhancement in heat transfer in turbulent flow does not come for free, however. It may be necessary to use a larger pump to overcome the larger friction forces accompanying the higher heat transfer rate.

## Reynolds Number

The transition from laminar to turbulent flow depends on the *surface geometry, surface roughness, flow velocity, surface temperature, and type of fluid*, among other things. After exhaustive experiments in the 1880s, Osborn Reynolds discovered that the flow regime depends mainly on the ratio of the *inertia forces* to *viscous forces* in the fluid. This ratio is called the **Reynolds number** (Fig. 6–21), which is a *dimensionless quantity*, and is expressed for external flow as (Fig. 6–22)

$$Re = \frac{\text{Inertia forces}}{\text{Viscous forces}} = \frac{VL_c}{\nu} = \frac{\rho VL_c}{\mu} \quad (6-13)$$

where  $V$  is the upstream velocity (equivalent to the free-stream velocity for a flat plate),  $L_c$  is the characteristic length of the geometry, and  $\nu = \mu/\rho$  is the kinematic viscosity of the fluid. For a flat plate, the characteristic length is the distance  $x$  from the leading edge. Note that kinematic viscosity has the unit  $\text{m}^2/\text{s}$ , which is identical to the unit of thermal diffusivity, and can be viewed as *viscous diffusivity* or *diffusivity for momentum*.

FIGURE 6–20

The behavior of colored fluid injected into the flow in laminar and turbulent flows in a pipe.

**FIGURE 6-21**

**Osborne Reynolds** (1842–1912), an English engineer and physicist best known for his work in the fields of hydraulics and hydrodynamics, was born in Belfast, Ireland. Reynolds' studies of condensation and the transfer of heat between solids and fluids brought about radical revisions in boiler and condenser design, and his work on turbine pumps laid the foundation for their rapid development. His classical paper on "The Law of Resistance in Parallel Channels" (1883) investigated the transition from smooth, or laminar, to turbulent flow. In 1886 he also formulated "The Theory of Lubrication" and later in 1889, he developed a mathematical framework which became the standard in turbulence work. His other work included the explanation of the radiometer and an early absolute determination of the mechanical equivalent of heat. The dimensionless **Reynolds number**, which provides a criterion for dynamic similarity and for correct modeling in many fluid flow experiments, is named after him.

*Courtesy of the Archives, California Institute of Technology.*

At *large* Reynolds numbers, the inertia forces, which are proportional to the density and the velocity of the fluid, are large relative to the viscous forces, and thus the viscous forces cannot prevent the random and rapid fluctuations of the fluid. At *small* or *moderate* Reynolds numbers, however, the viscous forces are large enough to suppress these fluctuations and to keep the fluid "in line." Thus the flow is *turbulent* in the first case and *laminar* in the second.

The Reynolds number at which the flow becomes turbulent is called the **critical Reynolds number**. The value of the critical Reynolds number is different for different geometries and flow conditions. For flow over a flat plate, the generally accepted value of the critical Reynolds number is  $Re_{cr} = Vx_{cr}/\nu = 5 \times 10^5$ , where  $x_{cr}$  is the distance from the leading edge of the plate at which transition from laminar to turbulent flow occurs. The value of  $Re_{cr}$  may change substantially, however, depending on the level of turbulence in the free stream.

## 6-6 ▪ HEAT AND MOMENTUM TRANSFER IN TURBULENT FLOW

Most flows encountered in engineering practice are turbulent, and thus it is important to understand how turbulence affects wall shear stress and heat transfer. However, turbulent flow is a complex mechanism dominated by fluctuations, and despite tremendous amounts of work done in this area by researchers, the theory of turbulent flow is still not fully understood. Therefore, we must rely on experiments and the empirical or semi-empirical correlations developed for various situations.

Turbulent flow is characterized by disorderly and rapid fluctuations of swirling regions of fluid, called **eddies**, throughout the flow. These fluctuations provide an additional mechanism for momentum and energy transfer. In laminar flow, fluid particles flow in an orderly manner along pathlines, and momentum and energy are transferred across streamlines by molecular diffusion. In turbulent flow, the swirling eddies transport mass, momentum, and energy to other regions of flow much more rapidly than molecular diffusion, greatly enhancing mass, momentum, and heat transfer. As a result, turbulent flow is associated with much higher values of friction, heat transfer, and mass transfer coefficients (Fig. 6-23).

Even when the average flow is steady, the eddy motion in turbulent flow causes significant fluctuations in the values of velocity, temperature, pressure, and even density (in compressible flow). Figure 6-24 shows the variation of the instantaneous velocity component  $u$  with time at a specified location, as can be measured with a hot-wire anemometer probe or other sensitive device. We observe that the instantaneous values of the velocity fluctuate about an average value, which suggests that the velocity can be expressed as the sum of an *average value*  $\bar{u}$  and a *fluctuating component*  $u'$ ,

$$u = \bar{u} + u' \quad (6-14)$$

This is also the case for other properties such as the velocity component  $v$  in the  $y$ -direction, and thus  $v = \bar{v} + v'$ ,  $P = \bar{P} + P'$ , and  $T = \bar{T} + T'$ . The average value of a property at some location is determined by averaging it over a time interval that is sufficiently large so that the time average levels off to a constant. Therefore, the time average of fluctuating components is zero, e.g.,  $\bar{u}' = 0$ . The magnitude of  $u'$  is usually just a few percent of  $\bar{u}$ , but the high frequencies of eddies (in the order of a thousand per second) makes them

very effective for the transport of momentum, thermal energy, and mass. In time-averaged *stationary* turbulent flow, the average values of properties (indicated by an overbar) are independent of time. The chaotic fluctuations of fluid particles play a dominant role in pressure drop, and these random motions must be considered in analyses together with the average velocity.

Perhaps the first thought that comes to mind is to determine the shear stress in an analogous manner to laminar flow from  $\tau = -\mu \frac{d\bar{u}}{dr}$ , where  $\bar{u}(r)$  is the average velocity profile for turbulent flow. But the experimental studies show that this is not the case, and the shear stress is much larger due to the turbulent fluctuations. Therefore, it is convenient to think of the turbulent shear stress as consisting of two parts: the *laminar component*, which accounts for the friction between layers in the flow direction (expressed as  $\tau_{\text{laminar}} = -\mu \frac{d\bar{u}}{dr}$ ), and the *turbulent component*, which accounts for the friction between the fluctuating fluid particles and the fluid body (denoted as  $\tau_{\text{turb}}$  and is related to the fluctuation components of velocity).

Consider turbulent flow in a horizontal pipe, and the upward eddy motion of fluid particles in a layer of lower velocity to an adjacent layer of higher velocity through a differential area  $dA$  as a result of the velocity fluctuation  $v'$ , as shown in Fig. 6–25. The mass flow rate of the fluid particles rising through  $dA$  is  $\rho v' dA$ , and its net effect on the layer above  $dA$  is a reduction in its average flow velocity because of momentum transfer to the fluid particles with lower average flow velocity. This momentum transfer causes the horizontal velocity of the fluid particles to increase by  $u'$ , and thus its momentum in the horizontal direction to increase at a rate of  $(\rho v' dA)u'$ , which must be equal to the decrease in the momentum of the upper fluid layer.

Noting that force in a given direction is equal to the rate of change of momentum in that direction, the horizontal force acting on a fluid element above  $dA$  due to the passing of fluid particles through  $dA$  is  $\delta F = (\rho v' dA)(-u') = -\rho u' v' dA$ . Therefore, the shear force per unit area due to the eddy motion of fluid particles  $\delta F/dA = -\rho u' v'$  can be viewed as the instantaneous turbulent shear stress. Then the **turbulent shear stress** can be expressed as  $\tau_{\text{turb}} = -\rho u' v'$  where  $u' v'$  is the time average of the product of the fluctuating velocity components  $u'$  and  $v'$ . Similarly, considering that  $h = c_p T$  represents the energy of the fluid and  $T'$  is the eddy temperature relative to the mean value, the rate of thermal energy transport by turbulent eddies is  $\dot{q}_{\text{turb}} = \rho c_p v' T'$ . Note that  $u' v' \neq 0$  even though  $\bar{u}' = 0$  and  $\bar{v}' = 0$  (and thus  $u' v' = 0$ ), and experimental results show that  $u' v'$  is usually a negative quantity. Terms such as  $-\rho u' v'$  or  $-\rho \bar{u}' \bar{v}'$  are called **Reynolds stresses** or **turbulent stresses**.

The random eddy motion of groups of particles resembles the random motion of molecules in a gas—colliding with each other after traveling a certain distance and exchanging momentum and heat in the process. Therefore, momentum and heat transport by eddies in turbulent boundary layers is analogous to the molecular momentum and heat diffusion. Then turbulent wall shear stress and turbulent heat transfer can be expressed in an analogous manner as

$$\tau_{\text{turb}} = -\rho \bar{u}' \bar{v}' = \mu_t \frac{\partial \bar{u}}{\partial y} \quad \text{and} \quad \dot{q}_{\text{turb}} = \rho c_p \bar{v}' \bar{T} = -k_t \frac{\partial T}{\partial y} \quad (6-15)$$

where  $\mu_t$  is called the **turbulent (or eddy) viscosity**, which accounts for momentum transport by turbulent eddies, and  $k_t$  is called the **turbulent (or eddy) thermal conductivity**, which accounts for thermal energy transport by turbulent

$$\begin{aligned} \text{Re} &= \frac{\text{Inertia forces}}{\text{Viscous forces}} \\ &= \frac{\rho V_{\text{avg}}^2 L}{\mu V_{\text{avg}} L} \\ &= \frac{\rho V_{\text{avg}} L}{\mu} \\ &= \frac{V_{\text{avg}} L}{\nu} \end{aligned}$$

FIGURE 6–22

The Reynolds number can be viewed as the ratio of inertial forces to viscous forces acting on a fluid element.

(a) Before turbulence (b) After turbulence

FIGURE 6–23

The intense mixing in turbulent flow brings fluid particles at different temperatures into close contact, and thus enhances heat transfer.

FIGURE 6–24

Fluctuations of the velocity component  $u$  with time at a specified location in turbulent flow.

**FIGURE 6-25**

Fluid particle moving upward through a differential area  $dA$  as a result of the velocity fluctuation  $v'$ .

eddies. Then the total shear stress and total heat flux can be expressed conveniently as

$$\tau_{\text{total}} = (\mu + \mu_t) \frac{\partial \bar{u}}{\partial y} = \rho(\nu + \nu_t) \frac{\partial \bar{u}}{\partial y} \quad (6-16)$$

and

$$\dot{q}_{\text{total}} = -(k + k_t) \frac{\partial \bar{T}}{\partial y} = -\rho c_p(\alpha + \alpha_t) \frac{\partial \bar{T}}{\partial y} \quad (6-17)$$

where  $\nu_t = \mu_t/\rho$  is the **kinematic eddy viscosity** (or **eddy diffusivity of momentum**) and  $\alpha_t = k_t/\rho c_p$  is the **eddy thermal diffusivity** (or **eddy diffusivity of heat**).

Eddy motion and thus eddy diffusivities are much larger than their molecular counterparts in the core region of a turbulent boundary layer. The eddy motion loses its intensity close to the wall, and diminishes at the wall because of the no-slip condition. Therefore, the velocity and temperature profiles are very slowly changing in the core region of a turbulent boundary layer, but very steep in the thin layer adjacent to the wall, resulting in large velocity and temperature gradients at the wall surface. So it is no surprise that the wall shear stress and wall heat flux are much larger in turbulent flow than they are in laminar flow (Fig. 6-26).

Note that molecular diffusivities  $\nu$  and  $\alpha$  (as well as  $\mu$  and  $k$ ) are fluid properties, and their values can be found listed in fluid handbooks. Eddy diffusivities  $\nu_t$  and  $\alpha_t$  (as well as  $\mu_t$  and  $k_t$ ), however are *not* fluid properties and their values depend on flow conditions. Eddy diffusivities  $\nu_t$  and  $\alpha_t$ , decrease towards the wall, becoming zero at the wall. Their values range from zero at the wall to several thousand times the values of molecular diffusivities in the core region.

## 6-7 • DERIVATION OF DIFFERENTIAL CONVECTION EQUATIONS\*

In this section we derive the governing equations of fluid flow in the boundary layers. To keep the analysis at a manageable level, we assume the flow to be steady and two-dimensional, and the fluid to be Newtonian with constant properties (density, viscosity, thermal conductivity, etc.).

Consider the parallel flow of a fluid over a surface. We take the flow direction along the surface to be  $x$  and the direction normal to the surface to be  $y$ , and we choose a differential volume element of length  $dx$ , height  $dy$ , and unit depth in the  $z$ -direction (normal to the paper) for analysis (Fig. 6-27). The fluid flows over the surface with a uniform free-stream velocity  $V$ , but the velocity within boundary layer is two-dimensional: the  $x$ -component of the velocity is  $u$ , and the  $y$ -component is  $v$ . Note that  $u = u(x, y)$  and  $v = v(x, y)$  in steady two-dimensional flow.

Next we apply three fundamental laws to this fluid element: Conservation of mass, conservation of momentum, and conservation of energy to obtain the continuity, momentum, and energy equations for laminar flow in boundary layers.

**FIGURE 6-26**

The velocity gradients at the wall, and thus the wall shear stress, are much larger for turbulent flow than they are for laminar flow, even though the turbulent boundary layer is thicker than the laminar one for the same value of free-stream velocity.

\*This and the upcoming sections of this chapter deal with theoretical aspects of convection, and can be skipped and be used as a reference if desired without a loss in continuity.

## The Continuity Equation

The conservation of mass principle is simply a statement that mass cannot be created or destroyed during a process and all the mass must be accounted for during an analysis. In steady flow, the amount of mass within the control volume remains constant, and thus the conservation of mass can be expressed as

$$\left( \begin{array}{l} \text{Rate of mass flow} \\ \text{into the control volume} \end{array} \right) = \left( \begin{array}{l} \text{Rate of mass flow} \\ \text{out of the control volume} \end{array} \right) \quad (6-18)$$

Noting that mass flow rate is equal to the product of density, average velocity, and cross-sectional area normal to flow, the rate at which fluid enters the control volume from the left surface is  $\rho u(dy \cdot 1)$ . The rate at which the fluid leaves the control volume from the right surface can be expressed as

$$\rho \left( u + \frac{\partial u}{\partial x} dx \right) (dy \cdot 1) \quad (6-19)$$

Repeating this for the  $y$  direction and substituting the results into Eq. 6-18, we obtain

$$\rho u(dy \cdot 1) + \rho v(dx \cdot 1) = \rho \left( u + \frac{\partial u}{\partial x} dx \right) (dy \cdot 1) + \rho \left( v + \frac{\partial v}{\partial y} dy \right) (dx \cdot 1) \quad (6-20)$$

Simplifying and dividing by  $dx \cdot dy \cdot 1$  gives

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (6-21)$$

This is the *conservation of mass* relation in differential form, which is also known as the **continuity equation** or **mass balance** for steady two-dimensional flow of a fluid with constant density.

## The Momentum Equations

The differential forms of the equations of motion in the velocity boundary layer are obtained by applying Newton's second law of motion to a differential control volume element in the boundary layer. Newton's second law is an expression for momentum balance and can be stated as *the net force acting on the control volume is equal to the mass times the acceleration of the fluid element within the control volume, which is also equal to the net rate of momentum outflow from the control volume*.

The forces acting on the control volume consist of *body forces* that act throughout the entire body of the control volume (such as gravity, electric, and magnetic forces) and are proportional to the volume of the body, and *surface forces* that act on the control surface (such as the pressure forces due to hydrostatic pressure and shear stresses due to viscous effects) and are proportional to the surface area. The surface forces appear as the control volume is isolated from its surroundings for analysis, and the effect of the detached body is replaced by a force at that location. Note that pressure represents the compressive force applied on the fluid element by the surrounding fluid, and is always directed to the surface.

We express Newton's second law of motion for the control volume as

$$(\text{Mass}) \left( \begin{array}{l} \text{Acceleration} \\ \text{in a specified direction} \end{array} \right) = \left( \begin{array}{l} \text{Net force (body and surface)} \\ \text{acting in that direction} \end{array} \right) \quad (6-22)$$

**FIGURE 6-27**

Differential control volume used in the derivation of mass balance in velocity boundary layer in two-dimensional flow over a surface.

or

$$\delta m \cdot a_x = F_{\text{surface},x} + F_{\text{body},x} \quad (6-23)$$

where the mass of the fluid element within the control volume is

$$\delta m = \rho(dx \cdot dy \cdot 1) \quad (6-24)$$

Noting that flow is steady and two-dimensional and thus  $u = u(x, y)$ , the total differential of  $u$  is

$$du = \frac{\partial u}{\partial x} dx + \frac{\partial u}{\partial y} dy \quad (6-25)$$

Then the acceleration of the fluid element in the  $x$  direction becomes

$$a_x = \frac{du}{dt} = \frac{\partial u}{\partial x} \frac{dx}{dt} + \frac{\partial u}{\partial y} \frac{dy}{dt} = u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \quad (6-26)$$

You may be tempted to think that acceleration is zero in steady flow since acceleration is the rate of change of velocity with time, and in steady flow there is no change with time. Well, a garden hose nozzle tells us that this understanding is not correct. Even in steady flow and thus constant mass flow rate, water accelerates through the nozzle (Fig. 6-28). *Steady* simply means no change with time at a specified location (and thus  $\partial u / \partial t = 0$ ), but the value of a quantity may change from one location to another (and thus  $\partial u / \partial x$  and  $\partial u / \partial y$  may be different from zero). In the case of a nozzle, the velocity of water remains constant at a specified point, but it changes from inlet to the exit (water accelerates along the nozzle, which is the reason for attaching a nozzle to the garden hose in the first place).

The forces acting on a surface are due to pressure and viscous effects. In two-dimensional flow, the *viscous stress* at any point on an imaginary surface within the fluid can be resolved into two perpendicular components: one normal to the surface called *normal stress* (which should not be confused with pressure) and another along the wall surface called *shear stress*. The normal stress is related to the velocity gradients  $\partial u / \partial x$  and  $\partial v / \partial y$ , that are much smaller than  $\partial u / \partial y$ , to which shear stress is related. Neglecting the normal stresses for simplicity, the surface forces acting on the control volume in the  $x$ -direction are as shown in Fig. 6-29. Then the net surface force acting in the  $x$ -direction becomes

$$\begin{aligned} F_{\text{surface},x} &= \left( \frac{\partial \tau}{\partial y} dy \right) (dx \cdot 1) - \left( \frac{\partial P}{\partial x} dx \right) (dy \cdot 1) = \left( \frac{\partial \tau}{\partial y} - \frac{\partial P}{\partial x} \right) (dx \cdot dy \cdot 1) \\ &= \left( \mu \frac{\partial^2 u}{\partial y^2} - \frac{\partial P}{\partial x} \right) (dx \cdot dy \cdot 1) \end{aligned} \quad (6-27)$$

since  $\tau = \mu(\partial u / \partial y)$ . Substituting Eqs. 6-24, 6-26, and 6-27 into Eq. 6-23 and dividing by  $dx \cdot dy \cdot 1$  gives

$$\rho \left( u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = \mu \frac{\partial^2 u}{\partial y^2} - \frac{\partial P}{\partial x} \quad (6-28)$$

This is the relation for the **momentum balance** in the  $x$ -direction, and is known as the **x-momentum equation**. Note that we would obtain the same result if we used momentum flow rates for the left-hand side of this equation instead of mass times acceleration. If there is a body force acting in the  $x$ -direction, it can be added to the right side of the equation provided that it is expressed per unit volume of the fluid.

**FIGURE 6-28**

During steady flow, a fluid may not accelerate in time at a fixed point, but it may accelerate in space.

**FIGURE 6-29**

Differential control volume used in the derivation of  $x$ -momentum equation in velocity boundary layer in two-dimensional flow over a surface.

In a boundary layer, the velocity component in the flow direction is much larger than that in the normal direction, and thus  $u \gg v$ , and  $\partial v / \partial x$  and  $\partial v / \partial y$  are negligible. Also,  $u$  varies greatly with  $y$  in the normal direction from zero at the wall surface to nearly the free-stream value across the relatively thin boundary layer, while the variation of  $u$  with  $x$  along the flow is typically small. Therefore,  $\partial u / \partial y \gg \partial u / \partial x$ . Similarly, if the fluid and the wall are at different temperatures and the fluid is heated or cooled during flow, heat conduction occurs primarily in the direction normal to the surface, and thus  $\partial T / \partial y \gg \partial T / \partial x$ . That is, the velocity and temperature gradients normal to the surface are much greater than those along the surface. These simplifications are known as the **boundary layer approximations**. These approximations greatly simplify the analysis usually with little loss in accuracy, and make it possible to obtain analytical solutions for certain types of flow problems (Fig. 6–30).

When gravity effects and other body forces are negligible and the boundary layer approximations are valid, applying Newton's second law of motion on the volume element in the  $y$ -direction gives the *y-momentum equation* to be

$$\frac{\partial P}{\partial y} = 0 \quad (6-29)$$

That is, *the variation of pressure in the direction normal to the surface is negligible*, and thus  $P = P(x)$  and  $\partial P / \partial x = dP/dx$ . Then it follows that for a given  $x$ , the pressure in the boundary layer is equal to the pressure in the free stream, and the pressure determined by a separate analysis of fluid flow in the free stream (which is typically easier because of the absence of viscous effects) can readily be used in the boundary layer analysis.

The velocity components in the free stream region of a flat plate are  $u = V = \text{constant}$  and  $v = 0$ . Substituting these into the  $x$ -momentum equations (Eq. 6–28) gives  $\partial P / \partial x = 0$ . Therefore, for flow over a flat plate, the pressure remains constant over the entire plate (both inside and outside the boundary layer).

## Conservation of Energy Equation

The energy balance for any system undergoing any process is expressed as  $E_{\text{in}} - E_{\text{out}} = \Delta E_{\text{system}}$ , which states that the change in the energy content of a system during a process is equal to the difference between the energy input and the energy output. During a *steady-flow process*, the total energy content of a control volume remains constant (and thus  $\Delta E_{\text{system}} = 0$ ), and the amount of energy entering a control volume in all forms must be equal to the amount of energy leaving it. Then the rate form of the general energy equation reduces for a steady-flow process to  $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} = 0$ .

Noting that energy can be transferred by heat, work, and mass only, the energy balance for a steady-flow control volume can be written explicitly as

$$(\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by heat}} + (\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by work}} + (\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by mass}} = 0 \quad (6-30)$$

The total energy of a flowing fluid stream per unit mass is  $e_{\text{stream}} = h + ke + pe$  where  $h$  is the enthalpy (which is the sum of internal energy and flow energy),  $pe = gz$  is the potential energy, and  $ke = V^2/2 = (u^2 + v^2)/2$  is the kinetic energy of the fluid per unit mass. The kinetic and potential energies are usually very small relative to enthalpy, and therefore it is common practice to neglect them (besides, it can be shown that if kinetic energy is included in the

- 1) Velocity components:  
 $u \gg v$
- 2) Velocity gradients:  
 $\frac{\partial v}{\partial x} \ll 0, \frac{\partial v}{\partial y} \ll 0$   
 $\frac{\partial u}{\partial y} \gg \frac{\partial u}{\partial x}$
- 3) Temperature gradients:  
 $\frac{\partial T}{\partial y} \gg \frac{\partial T}{\partial x}$

FIGURE 6–30

Boundary layer approximations.

FIGURE 6-31

The energy transfers by heat and mass flow associated with a differential control volume in the thermal boundary layer in steady two-dimensional flow.

following analysis, all the terms due to this inclusion cancel each other). We assume the density  $\rho$ , specific heat  $c_p$ , viscosity  $\mu$ , and the thermal conductivity  $k$  of the fluid to be constant. Then the energy of the fluid per unit mass can be expressed as  $e_{\text{stream}} = h = c_p T$ .

Energy is a scalar quantity, and thus energy interactions in all directions can be combined in one equation. Noting that mass flow rate of the fluid entering the control volume from the left is  $\rho u(dy \cdot 1)$ , the rate of energy transfer to the control volume by mass in the  $x$ -direction is, from Fig. 6-31,

$$\begin{aligned} (\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by mass, } x} &= (\dot{m}e_{\text{stream}})_x - \left[ (\dot{m}e_{\text{stream}})_x + \frac{\partial(\dot{m}e_{\text{stream}})_x}{\partial x} dx \right] \\ &= -\frac{\partial[\rho u(dy \cdot 1)c_p T]}{\partial x} dx = -\rho c_p \left( u \frac{\partial T}{\partial x} + T \frac{\partial u}{\partial x} \right) dxdy \end{aligned} \quad (6-31)$$

Repeating this for the  $y$ -direction and adding the results, the net rate of energy transfer to the control volume by mass is determined to be

$$\begin{aligned} (\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by mass}} &= -\rho c_p \left( u \frac{\partial T}{\partial x} + T \frac{\partial u}{\partial x} \right) dxdy - \rho c_p \left( v \frac{\partial T}{\partial y} + T \frac{\partial v}{\partial y} \right) dxdy \\ &= -\rho c_p \left( u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) dxdy \end{aligned} \quad (6-32)$$

since  $\partial u/\partial x + \partial v/\partial y = 0$  from the continuity equation.

The net rate of heat conduction to the volume element in the  $x$ -direction is

$$\begin{aligned} (\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by heat, } x} &= \dot{Q}_x - \left( \dot{Q}_x + \frac{\partial \dot{Q}_x}{\partial x} dx \right) = -\frac{\partial}{\partial x} \left( -k(dy \cdot 1) \frac{\partial T}{\partial x} \right) dx \\ &= k \frac{\partial^2 T}{\partial x^2} dxdy \end{aligned} \quad (6-33)$$

Repeating this for the  $y$ -direction and adding the results, the net rate of energy transfer to the control volume by heat conduction becomes

$$(\dot{E}_{\text{in}} - \dot{E}_{\text{out}})_{\text{by heat}} = k \frac{\partial^2 T}{\partial x^2} dxdy + k \frac{\partial^2 T}{\partial y^2} dxdy = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) dxdy \quad (6-34)$$

Another mechanism of energy transfer to and from the fluid in the control volume is the work done by the body and surface forces. The work done by a body force is determined by multiplying this force by the velocity in the direction of the force and the volume of the fluid element, and this work needs to be considered only in the presence of significant gravitational, electric, or magnetic effects. The surface forces consist of the forces due to fluid pressure and the viscous shear stresses. The work done by pressure (the flow work) is already accounted for in the analysis above by using enthalpy for the microscopic energy of the fluid instead of internal energy. The shear stresses that result from viscous effects are usually very small, and can be neglected in many cases. This is especially the case for applications that involve low or moderate velocities.

Then the energy equation for the steady two-dimensional flow of a fluid with constant properties and negligible shear stresses is obtained by substituting Eqs. 6-32 and 6-34 into 6-30 to be

$$\rho c_p \left( u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) \quad (6-35)$$

which states that *the net energy convected by the fluid out of the control volume is equal to the net energy transferred into the control volume by heat conduction.*

When the viscous shear stresses are not negligible, their effect is accounted for by expressing the energy equation as

$$\rho c_p \left( u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right) = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \mu \Phi \quad (6-36)$$

where the *viscous dissipation function*  $\Phi$  is obtained after a lengthy analysis (see an advanced book such as the one by Schlichting (1979) for details) to be

$$\Phi = 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right)^2 \quad (6-37)$$

Viscous dissipation may play a dominant role in high-speed flows, especially when the viscosity of the fluid is high (like the flow of oil in journal bearings). This manifests itself as a significant rise in fluid temperature due to the conversion of the kinetic energy of the fluid to thermal energy. Viscous dissipation is also significant for high-speed flights of aircraft.

For the special case of a stationary fluid,  $u = v = 0$ , the energy equation reduces, as expected, to the steady two-dimensional heat conduction equation,

$$\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} = 0 \quad (6-38)$$

### EXAMPLE 6–2 Temperature Rise of Oil in a Journal Bearing

The flow of oil in a journal bearing can be approximated as parallel flow between two large plates with one plate moving and the other stationary. Such flows are known as Couette flow.

Consider two large isothermal plates separated by 2-mm-thick oil film. The upper plate moves at a constant velocity of 12 m/s, while the lower plate is stationary. Both plates are maintained at 20°C. (a) Obtain relations for the velocity and temperature distributions in the oil. (b) Determine the maximum temperature in the oil and the heat flux from the oil to each plate (Fig. 6–32).

**SOLUTION** Parallel flow of oil between two plates is considered. The velocity and temperature distributions, the maximum temperature, and the total heat transfer rate are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Oil is an incompressible substance with constant properties. 3 Body forces such as gravity are negligible. 4 The plates are large so that there is no variation in the z direction.

**Properties** The properties of oil at 20°C are (Table A–13):

$$k = 0.145 \text{ W/m}\cdot\text{K} \quad \text{and} \quad \mu = 0.8374 \text{ kg/m}\cdot\text{s} = 0.8374 \text{ N}\cdot\text{s}/\text{m}^2$$

**Analysis** (a) We take the  $x$ -axis to be the flow direction, and  $y$  to be the normal direction. This is parallel flow between two plates, and thus  $v = 0$ . Then the continuity equation (Eq. 6–21) reduces to

$$\text{Continuity: } \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \rightarrow \frac{\partial u}{\partial x} = 0 \rightarrow u = u(y)$$

FIGURE 6–32

Schematic for Example 6–2.

Therefore, the  $x$ -component of velocity does not change in the flow direction (i.e., the velocity profile remains unchanged). Noting that  $u = u(y)$ ,  $v = 0$ , and  $\partial P/\partial x = 0$  (flow is maintained by the motion of the upper plate rather than the pressure gradient), the  $x$ -momentum equation (Eq. 6–28) reduces to

$$x\text{-momentum: } \rho \left( u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = \mu \frac{\partial^2 u}{\partial y^2} - \frac{\partial P}{\partial x} \rightarrow \frac{d^2 u}{dy^2} = 0$$

This is a second-order ordinary differential equation, and integrating it twice gives

$$u(y) = C_1 y + C_2$$

The fluid velocities at the plate surfaces must be equal to the velocities of the plates because of the no-slip condition. Therefore, the boundary conditions are  $u(0) = 0$  and  $u(L) = V$ , and applying them gives the velocity distribution to be

$$u(y) = \frac{y}{L} V$$

Frictional heating due to viscous dissipation in this case is significant because of the high viscosity of oil and the large plate velocity. The plates are isothermal and there is no change in the flow direction, and thus the temperature depends on  $y$  only,  $T = T(y)$ . Also,  $u = u(y)$  and  $v = 0$ . Then the energy equation with dissipation (Eqs. 6–36 and 6–37) reduce to

$$\text{Energy: } 0 = k \frac{\partial^2 T}{\partial y^2} + \mu \left( \frac{\partial u}{\partial y} \right)^2 \rightarrow k \frac{d^2 T}{dy^2} = -\mu \left( \frac{V}{L} \right)^2$$

since  $\partial u / \partial y = V/L$ . Dividing both sides by  $k$  and integrating twice give

$$T(y) = -\frac{\mu}{2k} \left( \frac{y}{L} V \right)^2 + C_3 y + C_4$$

Applying the boundary conditions  $T(0) = T_0$  and  $T(L) = T_0$  gives the temperature distribution to be

$$T(y) = T_0 + \frac{\mu V^2}{2k} \left( \frac{y}{L} - \frac{y^2}{L^2} \right)$$

(b) The temperature gradient is determined by differentiating  $T(y)$  with respect to  $y$ ,

$$\frac{dT}{dy} = \frac{\mu V^2}{2kL} \left( 1 - 2 \frac{y}{L} \right)$$

The location of maximum temperature is determined by setting  $dT/dy = 0$  and solving for  $y$ ,

$$\frac{dT}{dy} = \frac{\mu V^2}{2kL} \left( 1 - 2 \frac{y}{L} \right) = 0 \rightarrow y = \frac{L}{2}$$

Therefore, maximum temperature occurs at mid plane, which is not surprising since both plates are maintained at the same temperature. The maximum temperature is the value of temperature at  $y = L/2$ ,

$$\begin{aligned} T_{\max} &= T\left(\frac{L}{2}\right) = T_0 + \frac{\mu V^2}{2k} \left( \frac{L/2}{L} - \frac{(L/2)^2}{L^2} \right) = T_0 + \frac{\mu V^2}{8k} \\ &= 20 + \frac{(0.8374 \text{ N}\cdot\text{s}/\text{m}^2)(12 \text{ m/s})_2}{8(0.145 \text{ W/m}\cdot\text{K})} \left( \frac{1 \text{ W}}{1 \text{ N}\cdot\text{m/s}} \right) = 124^\circ\text{C} \end{aligned}$$

Heat flux at the plates is determined from the definition of heat flux,

$$\begin{aligned}\dot{q}_0 &= -k \frac{dT}{dy} \Big|_{y=0} = -k \frac{\mu V^2}{2kL} \Big| (1 - 0) = -\frac{\mu V^2}{2L} \\ &= -\frac{(0.8374 \text{ N}\cdot\text{s/m}^2)(12 \text{ m/s})^2}{2(0.002 \text{ m})} \left( \frac{1 \text{ kW}}{1000 \text{ N}\cdot\text{m/s}} \right) = -30.1 \text{ kW/m}^2 \\ \dot{q}_L &= -k \frac{dT}{dy} \Big|_{y=L} = -k \frac{\mu V^2}{2kL} (1 - 2) = \frac{\mu V^2}{2L} = -\dot{q}_0 = 30.1 \text{ kW/m}^2\end{aligned}$$

Therefore, heat fluxes at the two plates are equal in magnitude but opposite in sign.

**Discussion** A temperature rise of 104°C confirms our suspicion that viscous dissipation is very significant. Also, the heat flux is equivalent to the rate of mechanical energy dissipation. Therefore, mechanical energy is being converted to thermal energy at a rate of 60.2 kW/m<sup>2</sup> of plate area to overcome friction in the oil. Finally, calculations are done using oil properties at 20°C, but the oil temperature turned out to be much higher. Therefore, knowing the strong dependence of viscosity on temperature, calculations should be repeated using properties at the average temperature of 72°C to improve accuracy.

## 6-8 ■ SOLUTIONS OF CONVECTION EQUATIONS FOR A FLAT PLATE

Consider laminar flow of a fluid over a *flat plate*, as shown in Fig. 6-33. Surfaces that are slightly contoured such as turbine blades can also be approximated as flat plates with reasonable accuracy. The  $x$ -coordinate is measured along the plate surface from the leading edge of the plate in the direction of the flow, and  $y$  is measured from the surface in the normal direction. The fluid approaches the plate in the  $x$ -direction with a uniform upstream velocity, which is equivalent to the free stream velocity  $V$ .

When viscous dissipation is negligible, the continuity, momentum, and energy equations (Eqs. 6-21, 6-28, and 6-35) reduce for steady, incompressible, laminar flow of a fluid with constant properties over a flat plate to

$$\text{Continuity: } \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0 \quad (6-39)$$

$$\text{Momentum: } u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} = \nu \frac{\partial^2 u}{\partial y^2} \quad (6-40)$$

$$\text{Energy: } u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} = \alpha \frac{\partial^2 T}{\partial y^2} \quad (6-41)$$

with the boundary conditions (Fig. 6-26)

$$\text{At } x = 0: \quad u(0, y) = V, \quad T(0, y) = T_\infty$$

$$\text{At } y = 0: \quad u(x, 0) = 0, \quad v(x, 0) = 0, \quad T(x, 0) = T_w \quad (6-42)$$

$$\text{As } y \rightarrow \infty: \quad u(x, \infty) = V, \quad T(x, \infty) = T_\infty$$

When fluid properties are assumed to be constant and thus independent of temperature, the first two equations can be solved separately for the velocity

FIGURE 6-33

Boundary conditions for flow over a flat plate.

components  $u$  and  $v$ . Once the velocity distribution is available, we can determine the friction coefficient and the boundary layer thickness using their definitions. Also, knowing  $u$  and  $v$ , the temperature becomes the only unknown in the last equation, and it can be solved for temperature distribution.

The continuity and momentum equations were first solved in 1908 by the German engineer H. Blasius, a student of L. Prandtl. This was done by transforming the two partial differential equations into a single ordinary differential equation by introducing a new independent variable, called the **similarity variable**. The finding of such a variable, assuming it exists, is more of an art than science, and it requires to have a good insight of the problem.

Noticing that the general shape of the velocity profile remains the same along the plate, Blasius reasoned that the nondimensional velocity profile  $u/V$  should remain unchanged when plotted against the nondimensional distance  $y/\delta$ , where  $\delta$  is the thickness of the local velocity boundary layer at a given  $x$ . That is, although both  $\delta$  and  $u$  at a given  $y$  vary with  $x$ , the velocity  $u$  at a fixed  $y/\delta$  remains constant. Blasius was also aware from the work of Stokes that  $\delta$  is proportional to  $\sqrt{vx/V}$ , and thus he defined a *dimensionless similarity variable* as

$$\eta = y\sqrt{\frac{V}{vx}} \quad (6-43)$$

and thus  $u/V = \text{function}(\eta)$ . He then introduced a *stream function*  $\psi(x, y)$  as

$$u = \frac{\partial \psi}{\partial y} \quad \text{and} \quad v = -\frac{\partial \psi}{\partial x} \quad (6-44)$$

so that the continuity equation (Eq. 6-39) is automatically satisfied and thus eliminated (this can be verified easily by direct substitution). Next he defined a function  $f(\eta)$  as the dependent variable as

$$f(\eta) = \frac{\psi}{V\sqrt{vx/V}} \quad (6-45)$$

Then the velocity components become

$$u = \frac{\partial \psi}{\partial y} = \frac{\partial \psi}{\partial \eta} \frac{\partial \eta}{\partial y} = V \sqrt{\frac{vx}{V}} \frac{df}{d\eta} \sqrt{\frac{V}{vx}} = V \frac{df}{d\eta} \quad (6-46)$$

$$v = -\frac{\partial \psi}{\partial x} = -V \sqrt{\frac{vx}{V}} \frac{df}{d\eta} - \frac{V}{2} \sqrt{\frac{v}{vx}} f = \frac{1}{2} \sqrt{\frac{Vv}{x}} \left( \eta \frac{df}{d\eta} - f \right) \quad (6-47)$$

By differentiating these  $u$  and  $v$  relations, the derivatives of the velocity components can be shown to be

$$\frac{\partial u}{\partial x} = -\frac{V}{2x} \eta \frac{d^2 f}{d\eta^2}, \quad \frac{\partial u}{\partial y} = V \sqrt{\frac{V}{vx}} \frac{d^2 f}{d\eta^2}, \quad \frac{\partial^2 u}{\partial y^2} = \frac{V^2}{vx} \frac{d^3 f}{d\eta^3} \quad (6-48)$$

Substituting these relations into the momentum equation and simplifying, we obtain

$$2 \frac{d^3 f}{d\eta^3} + f \frac{d^2 f}{d\eta^2} = 0 \quad (6-49)$$

which is a third-order nonlinear differential equation. Therefore, the system of two partial differential equations is transformed into a single ordinary differential equation by the use of a similarity variable. Using the definitions

of  $f$  and  $\eta$ , the boundary conditions in terms of the similarity variables can be expressed as

$$f(0) = 0, \quad \left. \frac{df}{d\eta} \right|_{\eta=0} = 0, \quad \text{and} \quad \left. \frac{df}{d\eta} \right|_{\eta=\infty} = 1 \quad (6-50)$$

The transformed equation with its associated boundary conditions cannot be solved analytically, and thus an alternative solution method is necessary. The problem was first solved by Blasius in 1908 using a power series expansion approach, and this original solution is known as the *Blasius solution*. The problem is later solved more accurately using different numerical approaches, and results from such a solution are given in Table 6–3. The nondimensional velocity profile can be obtained by plotting  $u/V$  against  $\eta$ . The results obtained by this simplified analysis are in excellent agreement with experimental results.

Recall that we defined the boundary layer thickness as the distance from the surface for which  $u/V = 0.99$ . We observe from Table 6–3 that the value of  $\eta$  corresponding to  $u/V = 0.99$  is  $\eta = 4.91$ . Substituting  $\eta = 4.91$  and  $y = \delta$  into the definition of the similarity variable (Eq. 6–43) gives  $4.91 = \delta \sqrt{V/vx}$ . Then the velocity boundary layer thickness becomes

$$\delta = \frac{4.91}{\sqrt{V/vx}} = \frac{4.91x}{\sqrt{\text{Re}_x}} \quad (6-51)$$

since  $\text{Re}_x = Vx/v$ , where  $x$  is the distance from the leading edge of the plate. Note that the boundary layer thickness increases with increasing kinematic viscosity  $v$  and with increasing distance from the leading edge  $x$ , but it decreases with increasing free-stream velocity  $V$ . Therefore, a large free-stream velocity suppresses the boundary layer and causes it to be thinner.

The shear stress on the wall can be determined from its definition and the  $\partial u / \partial y$  relation in Eq. 6–48:

$$\tau_w = \mu \left. \frac{\partial u}{\partial y} \right|_{y=0} = \mu V \sqrt{\frac{V}{vx} \left. \frac{d^2 f}{d\eta^2} \right|_{\eta=0}} \quad (6-52)$$

Substituting the value of the second derivative of  $f$  at  $\eta = 0$  from Table 6–3 gives

$$\tau_w = 0.332V \sqrt{\frac{\rho \mu V}{x}} = \frac{0.332 \rho V^2}{\sqrt{\text{Re}_x}} \quad (6-53)$$

Then the local friction coefficient becomes

$$C_{f,x} = \frac{\tau_w}{\rho V^2/2} = 0.664 \text{ Re}_x^{-1/2} \quad (6-54)$$

Note that unlike the boundary layer thickness, wall shear stress and the skin friction coefficient decrease along the plate as  $x^{-1/2}$ .

## The Energy Equation

Knowing the velocity profile, we are now ready to solve the energy equation for temperature distribution for the case of constant wall temperature  $T_s$ . First we introduce the dimensionless temperature  $\theta$  as

$$\theta(x, y) = \frac{T(x, y) - T_s}{T_\infty - T_s} \quad (6-55)$$

| 5.0      | 3.283    | 0.992                            | 0.016                   |
| 5.5      | 3.781    | 0.997                            | 0.007                   |
| 6.0      | 4.280    | 0.999                            | 0.002                   |
| $\infty$ | $\infty$ | 1                                | 0                       |

Noting that both  $T_s$  and  $T_\infty$  are constant, substitution into the energy equation Eq. 6–41 gives

$$u \frac{\partial \theta}{\partial x} + v \frac{\partial \theta}{\partial y} = \alpha \frac{\partial^2 \theta}{\partial y^2} \quad (6-56)$$

Temperature profiles for flow over an isothermal flat plate are similar, just like the velocity profiles, and thus we expect a similarity solution for temperature to exist. Further, the thickness of the thermal boundary layer is proportional to  $\sqrt{vx/V}$ , just like the thickness of the velocity boundary layer, and thus the similarity variable is also  $\eta$ , and  $\theta = \theta(\eta)$ . Using the chain rule and substituting the  $u$  and  $v$  expressions from Eqs. 6–46 and 6–47 into the energy equation gives

$$V \frac{df}{d\eta} \frac{d\theta}{d\eta} \frac{\partial \eta}{\partial x} + \frac{1}{2} \sqrt{\frac{Vx}{V}} \left( \eta \frac{df}{d\eta} f \right) \frac{d\theta}{d\eta} \frac{\partial \eta}{\partial y} = \alpha \frac{d^2 \theta}{d\eta^2} \left( \frac{\partial \eta}{\partial y} \right)^2 \quad (6-57)$$

Simplifying and noting that  $\text{Pr} = v/\alpha$  gives

$$2 \frac{d^2 \theta}{d\eta^2} + \text{Pr} f \frac{d\theta}{d\eta} = 0 \quad (6-58)$$

with the boundary conditions  $\theta(0) = 0$  and  $\theta(\infty) = 1$ . Obtaining an equation for  $\theta$  as a function of  $\eta$  alone confirms that the temperature profiles are similar, and thus a similarity solution exists. Again a closed-form solution cannot be obtained for this boundary value problem, and it must be solved numerically.

It is interesting to note that for  $\text{Pr} = 1$ , this equation reduces to Eq. 6–49 when  $\theta$  is replaced by  $df/d\eta$ , which is equivalent to  $u/V$  (see Eq. 6–46). The boundary conditions for  $\theta$  and  $df/d\eta$  are also identical. Thus we conclude that the velocity and thermal boundary layers coincide, and the nondimensional velocity and temperature profiles ( $u/V$  and  $\theta$ ) are identical for steady, incompressible, laminar flow of a fluid with constant properties and  $\text{Pr} = 1$  over an isothermal flat plate (Fig. 6–34). The value of the temperature gradient at the surface ( $y = 0$  or  $\eta = 0$ ) in this case is, from Table 6–3,  $d\theta/d\eta = d^2f/d\eta^2 = 0.332$ .

Equation 6–58 is solved for numerous values of Prandtl numbers. For  $\text{Pr} > 0.6$ , the nondimensional temperature gradient at the surface is found to be proportional to  $\text{Pr}^{1/3}$ , and is expressed as

$$\left. \frac{d\theta}{d\eta} \right|_{\eta=0} = 0.332 \text{ Pr}^{1/3} \quad (6-59)$$

The temperature gradient at the surface is

$$\begin{aligned} \left. \frac{\partial T}{\partial y} \right|_{y=0} &= (T_\infty - T_s) \left. \frac{\partial \theta}{\partial y} \right|_{y=0} = (T_\infty - T_s) \left. \frac{d\theta}{d\eta} \right|_{\eta=0} \left. \frac{\partial \eta}{\partial y} \right|_{y=0} \\ &= 0.332 \text{ Pr}^{1/3} (T_\infty - T_s) \sqrt{\frac{V}{vx}} \end{aligned} \quad (6-60)$$

Then the local convection coefficient and Nusselt number become

$$h_x = \frac{\dot{q}_s}{T_s - T_\infty} = \frac{-k(\partial T/\partial y)|_{y=0}}{T_s - T_\infty} = 0.332 \text{ Pr}^{1/3} k \sqrt{\frac{V}{vx}} \quad (6-61)$$

**FIGURE 6–34**

When  $\text{Pr} = 1$ , the velocity and thermal boundary layers coincide, and the nondimensional velocity and temperature profiles are identical for steady, incompressible, laminar flow over a flat plate.

and

$$\text{Nu}_x = \frac{h_x x}{k} = 0.332 \text{Pr}^{1/3} \text{Re}_x^{1/2} \quad \text{Pr} > 0.6 \quad (6-62)$$

The  $\text{Nu}_x$  values obtained from this relation agree well with measured values.

Solving Eq. 6–58 numerically for the temperature profile for different Prandtl numbers, and using the definition of the thermal boundary layer, it is determined that  $\delta/\delta_t \cong \text{Pr}^{1/3}$ . Then the thermal boundary layer thickness becomes

$$\delta_t = \frac{\delta}{\text{Pr}^{1/3}} = \frac{4.91x}{\text{Pr}^{1/3} \sqrt{\text{Re}_x}} \quad (6-63)$$

Note that these relations are valid only for laminar flow over an isothermal flat plate. Also, the effect of variable properties can be accounted for by evaluating all such properties at the film temperature defined as  $T_f = (T_s + T_\infty)/2$ .

The Blasius solution gives important insights, but its value is largely historical because of the limitations it involves. Today both laminar and turbulent flows over surfaces are routinely analyzed using numerical methods.

## 6–9 • NONDIMENSIONALIZED CONVECTION EQUATIONS AND SIMILARITY

When viscous dissipation is negligible, the continuity, momentum, and energy equations for steady, laminar flow of a fluid with constant properties are given by Eqs. 6–28, 6–29, and 6–35.

These equations and the boundary conditions can be nondimensionalized by dividing all dependent and independent variables by relevant and meaningful constant quantities: all lengths by a characteristic length  $L$  (which is the length for a plate), all velocities by a reference velocity  $V$  (which is the free stream velocity for a plate), pressure by  $\rho V^2$  (which is twice the free stream dynamic pressure for a plate), and temperature by a suitable temperature difference (which is  $T_\infty - T_s$  for a plate). We get

$$x^* = \frac{x}{L}, \quad y^* = \frac{y}{L}, \quad u^* = \frac{u}{V}, \quad v^* = \frac{v}{V}, \quad P^* = \frac{P}{\rho V^2}, \quad \text{and} \quad T^* = \frac{T - T_s}{T_\infty - T_s}$$

where the asterisks are used to denote nondimensional variables. Introducing these variables into Eqs. 6–28, 6–29, and 6–35 and simplifying give

$$\text{Continuity:} \quad \frac{\partial u^*}{\partial x^*} + \frac{\partial v^*}{\partial y^*} = 0 \quad (6-64)$$

$$\text{Momentum:} \quad u^* \frac{\partial u^*}{\partial x^*} + v^* \frac{\partial u^*}{\partial y^*} = \frac{1}{\text{Re}_L} \frac{\partial^2 u^*}{\partial y^{*2}} - \frac{dP^*}{dx^*} \quad (6-65)$$

$$\text{Energy:} \quad u^* \frac{\partial T^*}{\partial x^*} + v^* \frac{\partial T^*}{\partial y^*} = \frac{1}{\text{Re}_L \text{Pr}} \frac{\partial^2 T^*}{\partial y^{*2}} \quad (6-66)$$

with the boundary conditions

$$u^*(0, y^*) = 1, \quad u^*(x^*, 0) = 0, \quad u^*(x^*, \infty) = 1, \quad v^*(x^*, 0) = 0, \quad (6-67)$$

$$T^*(0, y^*) = 1, \quad T^*(x^*, 0) = 0, \quad T^*(x^*, \infty) = 1$$

**FIGURE 6-35**

Two geometrically similar bodies have the same value of friction coefficient at the same Reynolds number.

Parameters before nondimensionalizing:  
 $L, V, T_\infty, T_s, \nu, \alpha$   
 Parameters after nondimensionalizing:  
 $\text{Re}, \text{Pr}$

**FIGURE 6-36**

The number of parameters is reduced greatly by nondimensionalizing the convection equations.

where  $\text{Re}_L = VL/\nu$  is the dimensionless Reynolds number and  $\text{Pr} = \nu/\alpha$  is the Prandtl number. For a given type of geometry, the solutions of problems with the same  $\text{Re}$  and  $\text{Nu}$  numbers are similar, and thus  $\text{Re}$  and  $\text{Nu}$  numbers serve as *similarity parameters*. Two physical phenomena are *similar* if they have the same dimensionless forms of governing differential equations and boundary conditions (Fig. 6-35).

A major advantage of nondimensionalizing is the significant reduction in the number of parameters. The original problem involves 6 parameters ( $L, V, T_\infty, T_s, \nu, \alpha$ ), but the nondimensionalized problem involves just 2 parameters ( $\text{Re}_L$  and  $\text{Pr}$ ). For a given geometry, problems that have the same values for the similarity parameters have identical solutions. For example, determining the convection heat transfer coefficient for flow over a given surface requires numerical solutions or experimental investigations for several fluids, with several sets of velocities, surface lengths, wall temperatures, and free stream temperatures. The same information can be obtained with far fewer investigations by grouping data into the dimensionless  $\text{Re}$  and  $\text{Pr}$  numbers. Another advantage of similarity parameters is that they enable us to group the results of a large number of experiments and to report them conveniently in terms of such parameters (Fig. 6-36).

## 6-10 • FUNCTIONAL FORMS OF FRICTION AND CONVECTION COEFFICIENTS

The three nondimensionalized boundary layer equations (Eqs. 6-64, 6-65, and 6-66) involve three unknown functions  $u^*$ ,  $v^*$ , and  $T^*$ , two independent variables  $x^*$  and  $y^*$ , and two parameters  $\text{Re}_L$  and  $\text{Pr}$ . The pressure  $P^*(x^*)$  depends on the geometry involved (it is constant for a flat plate), and it has the same value inside and outside the boundary layer at a specified  $x^*$ . Therefore, it can be determined separately from the free stream conditions, and  $dP^*/dx^*$  in Eq. 6-65 can be treated as a known function of  $x^*$ . Note that the boundary conditions do not introduce any new parameters.

For a given geometry, the solution for  $u^*$  can be expressed as

$$u^* = f_1(x^*, y^*, \text{Re}_L) \quad (6-68)$$

Then the shear stress at the surface becomes

$$\tau_w = \mu \frac{\partial u}{\partial y} \Big|_{y=0} = \frac{\mu V}{L} \frac{\partial u^*}{\partial y^*} \Big|_{y^*=0} = \frac{\mu V}{L} f_2(x^*, \text{Re}_L) \quad (6-69)$$

Substituting into its definition gives the local friction coefficient,

$$C_{f,x} = \frac{\tau_w}{\rho V^2/2} = \frac{\mu V/L}{\rho V^2/2} f_2(x^*, \text{Re}_L) = \frac{2}{\text{Re}_L} f_2(x^*, \text{Re}_L) = f_3(x^*, \text{Re}_L) \quad (6-70)$$

Thus we conclude that the friction coefficient for a given geometry can be expressed in terms of the Reynolds number  $\text{Re}$  and the dimensionless space variable  $x^*$  alone (instead of being expressed in terms of  $x, L, V, \rho$ , and  $\mu$ ). This is a very significant finding, and shows the value of nondimensionalized equations.

Similarly, the solution of Eq. 6–66 for the dimensionless temperature  $T^*$  for a given geometry can be expressed as

$$T^* = g_1(x^*, y^*, \text{Re}_L, \text{Pr}) \quad (6-71)$$

Using the definition of  $T^*$ , the convection heat transfer coefficient becomes

$$h_x = \frac{-k(\partial T/\partial y)|_{y=0}}{T_s - T_\infty} = \frac{-k(T_\infty - T_s)}{L(T_s - T_\infty)} \frac{\partial T^*}{\partial y^*}|_{y^*=0} = \frac{k}{L} \frac{\partial T^*}{\partial y^*}|_{y^*=0} \quad (6-72)$$

Substituting this into the Nusselt number relation gives [or alternately, we can rearrange the relation above in dimensionless form as  $hL/k = (\partial T^*/\partial y^*)|_{y^*=0}$  and define the dimensionless group  $hL/k$  as the Nusselt number]

$$\text{Nu}_x = \frac{h_x L}{k} = \frac{\partial T^*}{\partial y^*}|_{y^*=0} = g_2(x^*, \text{Re}_L, \text{Pr}) \quad (6-73)$$

Note that the Nusselt number is equivalent to the *dimensionless temperature gradient at the surface*, and thus it is properly referred to as the dimensionless heat transfer coefficient (Fig. 6–37). Also, the Nusselt number for a given geometry can be expressed in terms of the Reynolds number  $\text{Re}$ , the Prandtl number  $\text{Pr}$ , and the space variable  $x^*$ , and such a relation can be used for different fluids flowing at different velocities over similar geometries of different lengths.

The average friction and heat transfer coefficients are determined by integrating  $C_{f,x}$  and  $\text{Nu}_x$  over the surface of the given body with respect to  $x^*$  from 0 to 1. Integration removes the dependence on  $x^*$ , and the average friction coefficient and Nusselt number can be expressed as

$$C_f = f_4(\text{Re}_L) \quad \text{and} \quad \text{Nu} = g_3(\text{Re}_L, \text{Pr}) \quad (6-74)$$

These relations are extremely valuable as they state that for a given geometry, the friction coefficient can be expressed as a function of Reynolds number alone, and the Nusselt number as a function of Reynolds and Prandtl numbers alone (Fig. 6–38). Therefore, experimentalists can study a problem with a minimum number of experiments, and report their friction and heat transfer coefficient measurements conveniently in terms of Reynolds and Prandtl numbers. For example, a friction coefficient relation obtained with air for a given surface can also be used for water at the same Reynolds number. But it should be kept in mind that the validity of these relations is limited by the limitations on the boundary layer equations used in the analysis.

The experimental data for heat transfer is often represented with reasonable accuracy by a simple power-law relation of the form

$$\text{Nu} = C \text{Re}_L^m \text{Pr}^n \quad (6-75)$$

where  $m$  and  $n$  are constant exponents (usually between 0 and 1), and the value of the constant  $C$  depends on geometry. Sometimes more complex relations are used for better accuracy.

## 6–11 • ANALOGIES BETWEEN MOMENTUM AND HEAT TRANSFER

In forced convection analysis, we are primarily interested in the determination of the quantities  $C_f$  (to calculate shear stress at the wall) and  $\text{Nu}$  (to calculate heat transfer rates). Therefore, it is very desirable to have a relation between

**FIGURE 6–37**

The Nusselt number is equivalent to the dimensionless temperature gradient at the surface.

*Local Nusselt number:*  
 $\text{Nu}_x = \text{function}(x^*, \text{Re}_L, \text{Pr})$

*Average Nusselt number:*  
 $\text{Nu} = \text{function}(\text{Re}_L, \text{Pr})$

*A common form of Nusselt number:*  
 $\text{Nu} = C \text{Re}_L^m \text{Pr}^n$

**FIGURE 6–38**

For a given geometry, the average Nusselt number is a function of Reynolds and Prandtl numbers.

|            |   |
|------------|---|
| Profiles:  | $u^* = T^*$   |
| Gradients: | $\frac{\partial u^*}{\partial y^*} \Big _{y^*=0} = \frac{\partial T^*}{\partial y^*} \Big _{y^*=0}$ |
| Analogy:   | $C_{f,x} \frac{Re_L}{2} = Nu_x$   |

**FIGURE 6-39**

When  $Pr = 1$  and  $\partial P^*/\partial x^* \approx 0$ , the nondimensional velocity and temperature profiles become identical, and  $Nu$  is related to  $C_f$  by Reynolds analogy.

**FIGURE 6-40**

**Sir Thomas Edward Stanton** (1865–1931), was a British engineer, born at Atherstone in Warwickshire, England. From 1891 to 1896 he worked in Osborne Reynolds' laboratory at Owens College, Manchester, England. Stanton's main field of interest was fluid flow and friction, and the related problem of heat transmission. From 1902 to 1907 he executed a large research program concerning wind forces on structures, such as bridges and roofs. After 1908, the year when the Wright Brothers made their first airplane flights in Europe, Stanton was devoted to problems of airplane and airship design and the dissipation of heat from air-cooled engines. The dimensionless heat transfer coefficient **Stanton number** is named after him.

*Courtesy of University of Bristol.*

$C_f$  and  $Nu$  so that we can calculate one when the other is available. Such relations are developed on the basis of the similarity between momentum and heat transfers in boundary layers, and are known as *Reynolds analogy* (Fig. 6-21) and *Chilton–Colburn analogy*.

Reconsider the nondimensionalized momentum and energy equations for steady, incompressible, laminar flow of a fluid with constant properties and negligible viscous dissipation (Eqs. 6-65 and 6-66). When  $Pr = 1$  (which is approximately the case for gases) and  $\partial P^*/\partial x^* = 0$  (which is the case when,  $u = V = \text{constant}$  in the free stream, as in flow over a flat plate), these equations simplify to

$$\text{Momentum: } u^* \frac{\partial u^*}{\partial x^*} + v^* \frac{\partial u^*}{\partial y^*} = \frac{1}{Re_L} \frac{\partial^2 u^*}{\partial y^{*2}} \quad (6-76)$$

$$\text{Energy: } u^* \frac{\partial T^*}{\partial x^*} + v^* \frac{\partial T^*}{\partial y^*} = \frac{1}{Re_L} \frac{\partial^2 T^*}{\partial y^{*2}} \quad (6-77)$$

which are exactly of the same form for the dimensionless velocity  $u^*$  and temperature  $T^*$ . The boundary conditions for  $u^*$  and  $T^*$  are also identical. Therefore, the functions  $u^*$  and  $T^*$  must be identical, and thus the first derivatives of  $u^*$  and  $T^*$  at the surface must be equal to each other,

$$\frac{\partial u^*}{\partial y^*} \Big|_{y^*=0} = \frac{\partial T^*}{\partial y^*} \Big|_{y^*=0} \quad (6-78)$$

Then from Eqs. 6-69, 6-70, and 6-73 we have

$$C_{f,x} \frac{Re_L}{2} = Nu_x \quad (\text{Pr} = 1) \quad (6-79)$$

which is known as the **Reynolds analogy** (Fig. 6-39). This is an important analogy since it allows us to determine the heat transfer coefficient for fluids with  $Pr \approx 1$  from a knowledge of friction coefficient which is easier to measure. Reynolds analogy is also expressed alternately as

$$\frac{C_{f,x}}{2} = St_x \quad (\text{Pr} = 1) \quad (6-80)$$

where

$$St = \frac{h}{\rho c_p V} = \frac{Nu}{Re_L Pr} \quad (6-81)$$

which is the **Stanton number** (Fig. 6-40), which is also a dimensionless heat transfer coefficient.

Reynolds analogy is of limited use because of the restrictions  $Pr = 1$  and  $\partial P^*/\partial x^* = 0$  on it, and it is desirable to have an analogy that is applicable over a wide range of  $Pr$ . This is done by adding a Prandtl number correction.

The friction coefficient and Nusselt number for a flat plate were determined in Section 6-8 to be,

$$C_{f,x} = 0.664 Re_x^{-1/2} \quad \text{and} \quad Nu_x = 0.332 Pr^{1/3} Re_x^{1/2} \quad (6-82)$$

Taking their ratio and rearranging give the desired relation, known as the **modified Reynolds analogy** or **Chilton–Colburn analogy**,

$$C_{f,x} \frac{Re_L}{2} = Nu_x Pr^{-1/3} \quad \text{or} \quad \frac{C_{f,x}}{2} = St_x Pr^{2/3} = j_H \quad (6-83)$$

for  $0.6 < \text{Pr} < 60$ . Here  $j_H$  is called the *Colburn j-factor* (Fig. 6–41). Although this relation is developed using relations for laminar flow over a flat plate (for which  $\partial P^*/\partial x^* = 0$ ), experimental studies show that it is also applicable approximately for turbulent flow over a surface, even in the presence of pressure gradients. For laminar flow, however, the analogy is not applicable unless  $\partial P^*/\partial x^* \approx 0$ . Therefore, it does not apply to laminar flow in a pipe. Analogies between  $C_f$  and Nu that are more accurate are also developed, but they are more complex and beyond the scope of this book. The analogies given above can be used for both local and average quantities.

### EXAMPLE 6–3 Finding Convection Coefficient from Drag Measurement

A 2-m  $\times$  3-m flat plate is suspended in a room, and is subjected to air flow parallel to its surfaces along its 3-m-long side. The free stream temperature and velocity of air are 20°C and 7 m/s. The total drag force acting on the plate is measured to be 0.86 N. Determine the average convection heat transfer coefficient for the plate (Fig. 6–42).

**SOLUTION** A flat plate is subjected to air flow, and the drag force acting on it is measured. The average convection coefficient is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The edge effects are negligible. 3 The local atmospheric pressure is 1 atm.

**Properties** The properties of air at 20°C and 1 atm are (Table A–15):

$$\rho = 1.204 \text{ kg/m}^3, \quad c_p = 1.007 \text{ kJ/kg}\cdot\text{K}, \quad \text{Pr} = 0.7309$$

**Analysis** The flow is along the 3-m side of the plate, and thus the characteristic length is  $L = 3$  m. Both sides of the plate are exposed to air flow, and thus the total surface area is

$$A_s = 2WL = 2(2 \text{ m})(3 \text{ m}) = 12 \text{ m}^2$$

For flat plates, the drag force is equivalent to friction force. The average friction coefficient  $C_f$  can be determined from Eq. 6–11,

$$F_f = C_f A_s \frac{\rho V^2}{2}$$

Solving for  $C_f$  and substituting,

$$C_f = \frac{F_f}{\rho A_s V^2 / 2} = \frac{0.86 \text{ N}}{(1.204 \text{ kg/m}^3)(12 \text{ m}^2)(7 \text{ m/s})^2 / 2} \left( \frac{1 \text{ kg}\cdot\text{m/s}^2}{1 \text{ N}} \right) = 0.00243$$

Then the average heat transfer coefficient can be determined from the modified Reynolds analogy (Eq. 6–83) to be

$$h = \frac{C_f \rho V c_p}{2 \text{ Pr}^{2/3}} = \frac{0.00243}{2} \frac{(1.204 \text{ kg/m}^3)(7 \text{ m/s})(1007 \text{ J/kg}\cdot\text{K})}{0.7309^{2/3}} = 12.7 \text{ W/m}^2\cdot\text{K}$$

**Discussion** This example shows the great utility of momentum-heat transfer analogies in that the convection heat transfer coefficient can be obtained from a knowledge of friction coefficient, which is easier to determine.

FIGURE 6–41

**Allan Philip Colburn** (1904–1955), an American engineer, was born in Madison, Wisconsin. His research was on condensation of water vapor from saturated air streams. He brought together for the first time in American engineering work the fundamentals of momentum, heat and mass transfer along with thermodynamic principles to deal with this complex problem. The dimensionless empirical parameter **Colburn j-factor** ( $j_H = St_x \text{Pr}^{2/3}$ ) is named after him.

## TOPIC OF SPECIAL INTEREST

*Microscale Heat Transfer\**

Heat transfer considerations play a crucial role in the design and operation of many modern devices. New approaches and methods of analyses have been developed to understand and modulated (enhance or suppress) such energy interactions. Modulation typically occurs through actively controlling the surface phenomena, or focusing of the volumetric energy. In this section we discuss one such example—microscale heat transfer.

Recent inventions in micro ( $\sim 10^{-6}$  m) and nano ( $\sim 10^{-9}$  m) scale systems have shown tremendous benefits in fluid flow and heat transfer processes. These devices are extremely tiny and only visible through electron microscopes. The detailed understanding of the governing mechanism of these systems will be at the heart of realizing many future technologies. Examples include chemical and biological sensors, hydrogen storage, space exploration devices, and drug screening. Micro-nanoscale device development also poses several new challenges, however. For example, the classical heat transfer knowledge originates from thermal equilibrium approach and the equations are derived for material continuum. As the length scale of the system becomes minuscule, the heat transfer through these particles in nanoscale systems is no longer an equilibrium process and the continuum based equilibrium approach is no longer valid. Thus, a more general understanding of the concept of heat transfer becomes essential.

Both length and time scales are crucial in micro- and nanoscale heat transfer. The significance of length scale becomes evident from the fact that the surface area per unit volume of an object increases as the length scale of the object shrinks. This means the heat transfer through the surface becomes orders of magnitude more important in microscale than in large everyday objects. Transport of thermal energy in electronic and thermoelectric equipments often occurs at a range of length scales from millimeters to nanometers. For example, in a microelectronic chip (say MOSFET in Fig. 6–43) heat is generated in a nanometer-size drain region and ultimately conducted to the surrounding through substrates whose thickness is of the order of a millimeter. Clearly energy transport and conversion mechanisms in devices involve a wide range of length scales and are quite difficult to model.

Small time scales also play an important role in energy transport mechanisms. For example, ultra-short (pico-second and femto-second) pulse lasers are extremely useful for material processing industry. Here the tiny time scales permit localized laser-material interaction beneficial for high energy deposition and transport.

The applicability of the continuum model is determined by the local value of the non-dimensional Knudsen number ( $Kn$ ) which is defined as the ratio of the mean free path (mfp) of the heat-carrier medium to the system reference length scale (say thermal diffusion length). Microscale effects become

---

\*This section is contributed by Subrata Roy, Computational Plasma Dynamics Laboratory, Mechanical Engineering, Kettering University, Flint, MI.

**FIGURE 6–43**

Metal-Oxide Semiconductor Field-Effect Transistor (MOSFET) used in microelectronics.

important when the mfp becomes comparable to or greater than the reference length of the device, say at  $\text{Kn} > 0.001$ . As a result, thermophysical properties of materials become dependent on structure, and heat conduction processes are no longer local phenomena, but rather exhibit long-range radiative effects.

The conventional macroscopic Fourier conduction model violates this non-local feature of microscale heat transfer, and alternative approaches are necessary for analysis. The most suitable model to date is the concept of *phonon*. The thermal energy in a uniform solid material can be interpreted as the vibrations of a regular lattice of closely bound atoms inside. These atoms exhibit collective modes of sound waves (phonons) which transports energy at the speed of sound in a material. Following quantum mechanical principles, phonons exhibit particle-like properties of bosons with zero spin (wave-particle duality). Phonons play an important role in many of the physical properties of solids, such as the thermal and the electrical conductivities. In insulating solids, phonons are also the primary mechanism by which heat conduction takes place.

The variation of temperature near the bounding wall continues to be a major determinant of heat transfer through the surface. However, when the continuum approach breaks down, the conventional Newton's law of cooling using wall and bulk fluid temperature needs to be modified. Specifically, unlike in macroscale objects where the wall and adjacent fluid temperatures are equal ( $T_w = T_g$ ), in a micro device there is a temperature slip and the two values are different. One well known relation for calculating the temperature jump at the wall of a microgeometry was derived by von Smoluchowski in 1898,

$$T_g - T_w = \frac{2 - \sigma_T}{\sigma_T} \left[ \frac{2\gamma}{\gamma + 1} \right] \frac{\lambda}{\text{Pr}} \left( \frac{\partial T}{\partial y} \right)_w \quad (6-84)$$

where  $T$  is the temperature in K,  $\sigma_T$  is the thermal accommodation coefficient and indicates the molecular fraction reflected diffusively from the wall,  $\gamma$  is the specific heat ratio, and  $\text{Pr}$  is the Prandtl number. Once this value is known, the heat transfer rate may be calculated from:

$$-k \left( \frac{\partial T}{\partial y} \right)_w = \frac{\sigma_T \sqrt{2\pi RT}}{2 - \sigma_T} \left[ \frac{\gamma + 1}{2\gamma} \right] \frac{5\rho c_p}{16} (T_w - T_g) \quad (6-85)$$

As an example, the temperature distribution and Mach number contours inside a micro-tube of width  $H = 1.2 \mu\text{m}$  are plotted in Fig. 6–44 for supersonic

**FIGURE 6-44**

Fluid-thermal characteristics inside a microchannel.

From Raju and Roy, 2005.

flow of nitrogen and helium. For nitrogen gas with an inlet  $\text{Kn} = 0.062$ , the gas temperature ( $T_g$ ) adjacent to the wall differs substantially from the fixed wall temperature, as shown in Fig. 6-44a, where  $T_w$  is 323 K and  $T_g$  is almost 510 K. The effect of this wall heat transfer is to reduce the Mach number, as shown in Figure 6-44b, but the flow remains supersonic. For helium gas with inlet  $\text{Kn} = 0.14$  and a lower wall temperature of 298 K, the gas temperature immediately adjacent to the wall is even higher—up to 586 K, as shown in the Fig. 6-44c. This creates very high wall heat flux that is untenable in macroscale applications. In this case, shown in Fig. 6-44d, heat transfer is large enough to choke the flow.

## SUMMARY

Convection heat transfer is expressed by *Newton's law of cooling* as

$$\dot{Q}_{\text{conv}} = hA_s(T_s - T_\infty)$$

where  $h$  is the convection heat transfer coefficient,  $T_s$  is the surface temperature, and  $T_\infty$  is the free-stream temperature. The convection coefficient is also expressed as

$$h = \frac{-k_{\text{fluid}}(\partial T / \partial y)_{y=0}}{T_s - T_\infty}$$

The *Nusselt number*, which is the dimensionless heat transfer coefficient, is defined as

$$\text{Nu} = \frac{hL_c}{k}$$

where  $k$  is the thermal conductivity of the fluid and  $L_c$  is the characteristic length.

The highly ordered fluid motion characterized by smooth streamlines is called *laminar*. The highly disordered fluid motion that typically occurs at high velocities characterized by velocity fluctuations is called *turbulent*. The random and rapid fluctuations of groups of fluid particles, called *eddies*, provide an additional mechanism for momentum and heat transfer.

The region of the flow above the plate bounded by  $\delta$  in which the effects of the viscous shearing forces caused by fluid viscosity are felt is called the *velocity boundary layer*. The *boundary layer thickness*,  $\delta$ , is defined as the distance from the surface at which  $u = 0.99V$ . The hypothetical line of  $u = 0.99V$  divides the flow over a plate into the *boundary layer region* in which the viscous effects and the velocity changes are significant, and the *irrotational flow region*, in which the frictional effects are negligible.

The friction force per unit area is called *shear stress*, and the shear stress at the wall surface is expressed as

$$\tau_w = \mu \left. \frac{\partial u}{\partial y} \right|_{y=0} \quad \text{or} \quad \tau_w = C_f \frac{\rho V^2}{2}$$

where  $\mu$  is the dynamic viscosity,  $V$  is the upstream velocity, and  $C_f$  is the dimensionless *friction coefficient*. The property  $v = \mu/\rho$  is the *kinematic viscosity*. The friction force over the entire surface is determined from

$$F_f = C_f A_s \frac{\rho V^2}{2}$$

The flow region over the surface in which the temperature variation in the direction normal to the surface is significant is the *thermal boundary layer*. The *thickness* of the thermal boundary layer  $\delta_t$  at any location along the surface is the distance from the surface at which the temperature difference  $T - T_s$  equals  $0.99(T_\infty - T_s)$ . The relative thickness of the velocity and the thermal boundary layers is best described by the dimensionless *Prandtl number*, defined as

$$\text{Pr} = \frac{\text{Molecular diffusivity of momentum}}{\text{Molecular diffusivity of heat}} = \frac{v}{\alpha} = \frac{\mu c_p}{k}$$

For external flow, the dimensionless *Reynolds number* is expressed as

$$\text{Re} = \frac{\text{Inertia forces}}{\text{Viscous forces}} = \frac{VL_c}{v} = \frac{\rho VL_c}{\mu}$$

For a flat plate, the characteristic length is the distance  $x$  from the leading edge. The Reynolds number at which the flow becomes turbulent is called the *critical Reynolds number*. For flow over a flat plate, its value is taken to be  $\text{Re}_{\text{cr}} = Vx_{\text{cr}}/v = 5 \times 10^5$ .

The continuity, momentum, and energy equations for steady two-dimensional incompressible flow with constant properties are determined from mass, momentum, and energy balances to be

$$\text{Continuity: } \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

$$x\text{-momentum: } \rho \left( u \frac{\partial u}{\partial x} + v \frac{\partial u}{\partial y} \right) = \mu \frac{\partial^2 u}{\partial y^2} - \frac{\partial P}{\partial x}$$

$$\text{Energy: } \rho c_p \left[ u \frac{\partial T}{\partial x} + v \frac{\partial T}{\partial y} \right] = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) + \mu \Phi$$

where the *viscous dissipation function*  $\Phi$  is

$$\Phi = 2 \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial v}{\partial y} \right)^2 \right] + \left( \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right)^2$$

Using the boundary layer approximations and a similarity variable, these equations can be solved for parallel steady incompressible flow over a flat plate, with the following results:

$$\text{Velocity boundary layer thickness: } \delta = \frac{4.91}{\sqrt{V/vx}} = \frac{4.91x}{\sqrt{\text{Re}_x}}$$

$$\text{Local friction coefficient: } C_{f,x} = \frac{\tau_w}{\rho V^2/2} = 0.664 \text{ Re}_x^{-1/2}$$

$$\text{Local Nusselt number: } \text{Nu}_x = \frac{h_x x}{k} = 0.332 \text{ Pr}^{1/3} \text{ Re}_x^{1/2}$$

$$\text{Thermal boundary layer thickness: } \delta_t = \frac{\delta}{\text{Pr}^{1/3}} = \frac{4.91x}{\text{Pr}^{1/3}\sqrt{\text{Re}_x}}$$

The average friction coefficient and Nusselt number are expressed in functional form as

$$C_f = f(\text{Re}_L) \quad \text{and} \quad \text{Nu} = g(\text{Re}_L, \text{Pr})$$

The Nusselt number can be expressed by a simple power-law relation of the form

$$\text{Nu} = C \text{Re}_L^m \text{Pr}^n$$

where  $m$  and  $n$  are constant exponents, and the value of the constant  $C$  depends on geometry. The *Reynolds analogy* relates the convection coefficient to the friction coefficient for fluids with  $\text{Pr} \approx 1$ , and is expressed as

$$C_{f,x} \frac{\text{Re}_L}{2} = \text{Nu}_x \quad \text{or} \quad \frac{C_{f,x}}{2} = \text{St}_x$$

where

$$\text{St} = \frac{h}{\rho c_p V} = \frac{\text{Nu}}{\text{Re}_L \text{Pr}}$$

is the *Stanton number*. The analogy is extended to other Prandtl numbers by the *modified Reynolds analogy* or *Chilton–Colburn analogy*, expressed as

$$C_{f,x} \frac{\text{Re}_L}{2} = \text{Nu}_x \text{Pr}^{-1/3}$$

or

$$\frac{C_{f,x}}{2} = \text{St}_x \text{Pr}^{2/3} = j_H (0.6 < \text{Pr} < 60)$$

These analogies are also applicable approximately for turbulent flow over a surface, even in the presence of pressure gradients.

**PROBLEMS\*****Mechanism and Types of Convection**

**6–1C** Define incompressible flow and incompressible fluid. Must the flow of a compressible fluid necessarily be treated as compressible?

**6–2C** What is forced convection? How does it differ from natural convection? Is convection caused by winds forced or natural convection?

**6–3C** What is external forced convection? How does it differ from internal forced convection? Can a heat transfer system involve both internal and external convection at the same time? Give an example.

**6–4C** In which mode of heat transfer is the convection heat transfer coefficient usually higher, natural convection or forced convection? Why?

**6–5C** Consider a hot baked potato. Will the potato cool faster or slower when we blow the warm air coming from our lungs on it instead of letting it cool naturally in the cooler air in the room? Explain.

**6–6C** What is the physical significance of the Nusselt number? How is it defined?

**6–7C** When is heat transfer through a fluid conduction and when is it convection? For what case is the rate of heat transfer higher? How does the convection heat transfer coefficient differ from the thermal conductivity of a fluid?

**6–8** An average man has a body surface area of  $1.8 \text{ m}^2$  and a skin temperature of  $33^\circ\text{C}$ . The convection heat transfer coefficient for a clothed person walking in still air is expressed as  $h = 8.6V^{0.53}$  for  $0.5 < V < 2 \text{ m/s}$ , where  $V$  is the walking velocity in m/s. Assuming the average surface temperature of the clothed person to be  $30^\circ\text{C}$ , determine the rate of heat loss from an average man walking in still air at  $10^\circ\text{C}$  by convection at a walking velocity of (a)  $0.5 \text{ m/s}$ , (b)  $1.0 \text{ m/s}$ , (c)  $1.5 \text{ m/s}$ , and (d)  $2.0 \text{ m/s}$ .

**6–9** The convection heat transfer coefficient for a clothed person standing in moving air is expressed as  $h = 14.8V^{0.69}$  for  $0.15 < V < 1.5 \text{ m/s}$ , where  $V$  is the air velocity. For a person with a body surface area of  $1.7 \text{ m}^2$  and an average surface temperature of  $29^\circ\text{C}$ , determine the rate of heat loss from the person in windy air at  $10^\circ\text{C}$  by convection for air velocities of (a)  $0.5 \text{ m/s}$ , (b)  $1.0 \text{ m/s}$ , and (c)  $1.5 \text{ m/s}$ .

\*Problems designated by a "C" are concept questions, and students are encouraged to answer them all. Problems designated by an "E" are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature, and are intended to be solved with an equation solver such as EES.

**6–10** During air cooling of potatoes, the heat transfer coefficient for combined convection, radiation, and evaporation is determined experimentally to be as shown:

| Air Velocity, m/s | Heat Transfer Coefficient,<br>$\text{W/m}^2\cdot\text{K}$ |
|-------------------|---|
| 0.66              | 14.0  |
| 1.00              | 19.1  |
| 1.36              | 20.2  |
| 1.73              | 24.4  |

Consider an 8-cm-diameter potato initially at  $20^\circ\text{C}$ . Potatoes are cooled by refrigerated air at  $5^\circ\text{C}$  at a velocity of  $1 \text{ m/s}$ . Determine the initial rate of heat transfer from a potato, and the initial value of the temperature gradient in the potato at the surface.

**6–11** The upper surface of a 50-cm-thick solid plate ( $k = 237 \text{ W/m}\cdot\text{K}$ ) is being cooled by water with temperature of  $20^\circ\text{C}$ . The upper and lower surfaces of the solid plate maintained at constant temperatures of  $60^\circ\text{C}$  and  $120^\circ\text{C}$ , respectively. Determine the water convection heat transfer coefficient and the water temperature gradient at the upper plate surface.

**FIGURE P6–11**

**6–12** Consider airflow over a plate surface maintained at a temperature of  $220^\circ\text{C}$ . The temperature profile of the airflow is given as

$$T(y) = T_\infty - (T_\infty - T_s) \exp\left(-\frac{V}{\alpha_{\text{fluid}}}y\right)$$

The airflow at 1 atm has a free stream velocity and temperature of  $0.08 \text{ m/s}$  and  $20^\circ\text{C}$ , respectively. Determine the heat flux on the plate surface and the convection heat transfer coefficient of the airflow.

**6–13** During air cooling of oranges, grapefruit, and tangelos, the heat transfer coefficient for combined convection, radiation, and evaporation for air velocities of  $0.11 < V < 0.33 \text{ m/s}$  is determined experimentally and is expressed as  $h = 5.05 k_{\text{air}} \text{Re}^{1/3}/D$ , where the diameter  $D$

is the characteristic length. Oranges are cooled by refrigerated air at 5°C and 1 atm at a velocity of 0.3 m/s. Determine (a) the initial rate of heat transfer from a 7-cm-diameter orange initially at 15°C with a thermal conductivity of 0.50 W/m·K, (b) the value of the initial temperature gradient inside the orange at the surface, and (c) the value of the Nusselt number.

**FIGURE P6–13**

**6–14** During air cooling of steel balls, the convection heat transfer coefficient is determined experimentally as a function of air velocity to be  $h = 17.9V^{0.54}$  for  $0.5 < V < 2$  m/s, where  $h$  and  $V$  are in  $\text{W}/\text{m}^2\cdot\text{K}$  and m/s, respectively. Consider a 24-mm-diameter steel ball initially at 300°C with a thermal conductivity of 15  $\text{W}/\text{m}\cdot\text{K}$ . The steel balls are cooled in air at 10°C and a velocity of 1.5 m/s. Determine the initial values of the heat flux and the temperature gradient in the steel ball at the surface.

**6–15** A ball bearing manufacturing plant is using air to cool chromium steel balls ( $k = 40 \text{ W}/\text{m}\cdot\text{K}$ ). The convection heat transfer coefficient for the cooling is determined experimentally as a function of air velocity to be  $h = 18.05V^{0.56}$ , where  $h$  and  $V$  are in  $\text{W}/\text{m}^2\cdot\text{K}$  and m/s, respectively. At a given moment during the cooling process with the air temperature at 5°C, a chromium steel ball has a surface temperature of 450°C. Using EES (or other) software, determine the effect of the air velocity ( $V$ ) on the temperature gradient in the chromium steel ball at the surface. By varying the air velocity from 0.2 to 2.4 m/s with increments of 0.2 m/s, plot the temperature gradient in the chromium steel ball at the surface as a function of air velocity.

**6–16** Consider the surface of a metal plate being cooled by forced convection. Determine the ratio of the temperature gradient in the fluid to the temperature gradient in the metal plate at the surface.

**6–17** A metal plate is being cooled by air ( $k_{\text{fluid}} = 0.259 \text{ W}/\text{m}\cdot\text{K}$ ) at the upper surface while the lower surface is subjected to a uniform heat flux of  $1000 \text{ W}/\text{m}^2$ . Determine the temperature gradient in the air at the upper surface of the metal plate.

**FIGURE P6–17**

**6–18** The top surface of a metal plate ( $k_{\text{plate}} = 237 \text{ W}/\text{m}\cdot\text{K}$ ) is being cooled by air ( $k_{\text{air}} = 0.243 \text{ W}/\text{m}\cdot\text{K}$ ) while the bottom surface is exposed to a hot steam at 100°C with a convection heat transfer coefficient of  $30 \text{ W}/\text{m}^2\cdot\text{K}$ . If the bottom surface temperature of the plate is 80°C, determine the temperature gradient in the air and the temperature gradient in the plate at the top surface of the plate.

**FIGURE P6–18**

**6–19** During air cooling of a flat plate ( $k = 1.4 \text{ W}/\text{m}\cdot\text{K}$ ), the convection heat transfer coefficient is given as a function of air velocity to be  $h = 27V^{0.85}$ , where  $h$  and  $V$  are in  $\text{W}/\text{m}^2\cdot\text{K}$  and m/s, respectively. At a given moment, the surface temperature of the plate is 75°C and the air ( $k = 0.266 \text{ W}/\text{m}\cdot\text{K}$ ) temperature is 5°C. Using EES (or other) software, determine the effect of the air velocity ( $V$ ) on the air temperature gradient at the plate surface. By varying the air velocity from 0 to 1.2 m/s with increments of 0.1 m/s, plot the air temperature gradient at the plate surface as a function of air velocity.

**6–20** A metal plate ( $k = 180 \text{ W}/\text{m}\cdot\text{K}$ ,  $\rho = 2800 \text{ kg}/\text{m}^3$ , and  $c_p = 880 \text{ J}/\text{kg}\cdot\text{K}$ ) with a thickness of 1 cm is being cooled by air at 5°C with a convection heat transfer coefficient of  $30 \text{ W}/\text{m}^2\cdot\text{K}$ . If the initial temperature of the plate is 300°C, determine the plate temperature gradient at the surface after 2 minutes of cooling. Hint: Use the lumped system analysis to calculate the plate surface temperature. Make sure to verify the application of this method to this problem.

**6–21** Air at 5°C, with a convection heat transfer coefficient of  $30 \text{ W}/\text{m}^2\cdot\text{K}$ , is used for cooling metal plates coming out of a heat treatment oven at an initial

temperature of  $300^\circ\text{C}$ . The plates ( $k = 180 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg}\cdot\text{K}$ ) have a thickness of 10 mm. Using EES (or other) software, determine the effect of cooling time on the temperature gradient in the metal plates at the surface. By varying the cooling time from 0 to 3000 s, plot the temperature gradient in the plates at the surface as a function of cooling time. Hint: Use the lumped system analysis to calculate the plate surface temperature. Make sure to verify the application of this method to this problem.

**6-22** A 5-mm-thick stainless steel strip ( $k = 21 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8000 \text{ kg/m}^3$ , and  $c_p = 570 \text{ J/kg}\cdot\text{K}$ ) is being heat treated as it moves through a furnace at a speed of 1 cm/s. The air temperature in the furnace is maintained at  $900^\circ\text{C}$  with a convection heat transfer coefficient of  $80 \text{ W/m}^2\cdot\text{K}$ . If the furnace length is 3 m and the stainless steel strip enters it at  $20^\circ\text{C}$ , determine the surface temperature gradient of the strip at mid-length of the furnace. Hint: Use the lumped system analysis to calculate the plate surface temperature. Make sure to verify the application of this method to this problem.

**6-23**  A long steel strip is being conveyed through a 3-m long furnace to be heat treated at a speed of 0.01 m/s. The steel strip ( $k = 21 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8000 \text{ kg/m}^3$ , and  $c_p = 570 \text{ J/kg}\cdot\text{K}$ ) has a thickness of 5 mm, and it enters the furnace at an initial temperature of  $20^\circ\text{C}$ . Inside the furnace, the air temperature is maintained at  $900^\circ\text{C}$  with a convection heat transfer coefficient of  $80 \text{ W/m}^2\cdot\text{K}$ . Using EES (or other) software, determine the surface temperature gradient of the steel strip as a function of location inside the furnace. By varying the location in the furnace for  $0 \leq x \leq 3 \text{ m}$  with increments of 0.2 m, plot the surface temperature gradient of the strip as a function of furnace location. Hint: Use the lumped system analysis to calculate the plate surface temperature. Make sure to verify the application of this method to this problem.

### Boundary Layers and Flow Regimes

**6-24C** What is the no-slip condition? What causes it?

**6-25C** What is Newtonian fluid? Is water a Newtonian fluid?

**6-26C** What is viscosity? What causes viscosity in liquids and in gases? Is dynamic viscosity typically higher for a liquid or for a gas?

**6-27C** Consider two identical small glass balls dropped into two identical containers, one filled with water and the other with oil. Which ball will reach the bottom of the container first? Why?

**6-28C** How does the dynamic viscosity of (a) liquids and (b) gases vary with temperature?

**6-29C** What fluid property is responsible for the development of the velocity boundary layer? For what kind of fluids will there be no velocity boundary layer on a flat plate?

**6-30C** What is the physical significance of the Prandtl number? Does the value of the Prandtl number depend on the type of flow or the flow geometry? Does the Prandtl number of air change with pressure? Does it change with temperature?

**6-31C** Will a thermal boundary layer develop in flow over a surface even if both the fluid and the surface are at the same temperature?

**6-32C** What is the physical significance of the Reynolds number? How is it defined for external flow over a plate of length  $L$ ?

**6-33C** How does turbulent flow differ from laminar flow? For which flow is the heat transfer coefficient higher?

**6-34C** What does the friction coefficient represent in flow over a flat plate? How is it related to the drag force acting on the plate?

**6-35C** What is the physical mechanism that causes the friction factor to be higher in turbulent flow?

**6-36C** What is turbulent viscosity? What is it caused by?

**6-37C** What is turbulent thermal conductivity? What is it caused by?

**6-38** Consider fluid flow over a surface with a velocity profile given as

$$u(y) = 100(y + 2y^2 - 0.5y^3) \text{ m/s}$$

Determine the shear stress at the wall surface, if the fluid is (a) air at 1 atm and (b) liquid water, both at  $20^\circ\text{C}$ . Also calculate the wall shear stress ratio for the two fluids and interpret the result.

**6-39** Consider a flow over a surface with the velocity and temperature profiles given as

$$u(y) = C_1(y + y^2 - y^3)$$

$$T(y) = C_2 - e^{-2C_2y}$$

where the coefficients  $C_1$  and  $C_2$  are constants. Determine the expressions for the friction coefficient ( $C_f$ ) and the convection heat transfer coefficient ( $h$ ).

**6-40** Air flowing over a 1-m-long flat plate at a velocity of 7 m/s has a friction coefficient given as  $C_f = 0.664(Vx/\nu)^{-0.5}$ , where  $x$  is the location along the plate. Determine the wall shear stress and the air velocity gradient on the plate surface at mid-length of the plate. Evaluate the air properties at  $20^\circ\text{C}$  and 1 atm.

**6-41**  Friction coefficient of air flowing over a flat plate is given as  $C_f = 0.664(Vx/\nu)^{-0.5}$ , where  $x$  is the location along the plate. Using EES (or other) software, determine the effect of the air velocity ( $V$ ) on the wall shear stress ( $\tau_w$ ) at the plate locations of  $x = 0.5$  m and 1 m. By varying the air velocity from 0.5 to 6 m/s with increments of 0.5 m/s, plot the wall shear stress as a function of air velocity at  $x = 0.5$  m and 1 m. Evaluate the air properties at 20°C and 1 atm.

**6-42**  Air flowing over a flat plate at 5 m/s has a friction coefficient given as  $C_f = 0.664(Vx/\nu)^{-0.5}$ , where  $x$  is the location along the plate. Using EES (or other) software, determine the effect of the location along the plate ( $x$ ) on the wall shear stress ( $\tau_w$ ). By varying  $x$  from 0.01 to 1 m, plot the wall shear stress as a function of  $x$ . Evaluate the air properties at 20°C and 1 atm.

**6-43** Consider a flat plate positioned inside a wind tunnel, and air at 1 atm and 20°C is flowing with a free stream velocity of 60 m/s. What is the minimum length of the plate necessary for the Reynolds number to reach  $2 \times 10^7$ ? If the critical Reynolds number is  $5 \times 10^5$ , what type of flow regime would the airflow experience at 0.2 m from the leading edge?

**6-44** Air flows over a flat plate at 40 m/s, 25°C and 1 atm pressure. (a) What plate length should be used to achieve a Reynolds number of  $1 \times 10^8$  at the end of the plate? (b) If the critical Reynolds number is  $5 \times 10^5$ , at what distance from the leading edge of the plate would transition occur?

**6-45** Consider fluid flowing with a free stream velocity of 5 m/s over a flat plate, where the critical Reynolds number is  $5 \times 10^5$ . Determine the distance from the leading edge at which the transition from laminar to turbulent flow occurs for air (at 1 atm), liquid water, methanol, and engine oil, all at 20°C, and mercury at 25°C.

**6-46E** Consider fluid flowing with a free stream velocity of 1 ft/s over a flat plate, where the critical Reynolds number is  $5 \times 10^5$ . Determine the distance from the leading edge at which the transition from laminar to turbulent flow occurs for air (at 1 atm), liquid water, isobutane, and engine oil, and mercury. Evaluate all properties at 50°F.

### Convection Equations and Similarity Solutions

**6-47C** Consider steady, laminar, two-dimensional, incompressible flow with constant properties and a Prandtl number of unity. For a given geometry, is it correct to say that both the average friction and heat transfer coefficients depend on the Reynolds number only?

**6-48C** Express continuity equation for steady two-dimensional flow with constant properties, and explain what each term represents.

**6-49C** Is the acceleration of a fluid particle necessarily zero in steady flow? Explain.

**6-50C** For steady two-dimensional flow, what are the boundary layer approximations?

**6-51C** For what types of fluids and flows is the viscous dissipation term in the energy equation likely to be significant?

**6-52C** For steady two-dimensional flow over an isothermal flat plate in the  $x$ -direction, express the boundary conditions for the velocity components  $u$  and  $v$ , and the temperature  $T$  at the plate surface and at the edge of the boundary layer.

**6-53C** What is a similarity variable, and what is it used for? For what kinds of functions can we expect a similarity solution for a set of partial differential equations to exist?

**6-54C** Consider steady, laminar, two-dimensional flow over an isothermal plate. Does the thickness of the velocity boundary layer increase or decrease with (a) distance from the leading edge, (b) free-stream velocity, and (c) kinematic viscosity?

**6-55C** Consider steady, laminar, two-dimensional flow over an isothermal plate. Does the wall shear stress increase, decrease, or remain constant with distance from the leading edge?

**6-56C** What are the advantages of nondimensionalizing the convection equations?

**6-57C** Under what conditions can a curved surface be treated as a flat plate in fluid flow and convection analysis?

**6-58** Consider a 5-cm-diameter shaft rotating at 4000 rpm in a 25-cm-long bearing with a clearance of 0.5 mm. Determine the power required to rotate the shaft if the fluid in the gap is (a) air, (b) water, and (c) oil at 40°C and 1 atm.

**6-59** Oil flow in a journal bearing can be treated as parallel flow between two large isothermal plates with one plate moving at a constant velocity of 12 m/s and the other stationary. Consider such a flow with a uniform spacing of 0.7 mm between the plates. The temperatures of the upper and lower plates are 40°C and 15°C, respectively. By simplifying and solving the continuity, momentum, and energy equations, determine (a) the velocity and temperature distributions in the oil, (b) the maximum temperature and where it occurs, and (c) the heat flux from the oil to each plate.

FIGURE P6-59

**6-60** Repeat Prob. 6-59 for a spacing of 0.4 mm.

**6-61** Consider the flow of fluid between two large parallel isothermal plates separated by a distance  $L$ . The upper plate is moving at a constant velocity of  $V$  and maintained at temperature  $T_0$  while the lower plate is stationary and insulated. By simplifying and solving the continuity, momentum, and

energy equations, obtain relations for the maximum temperature of fluid, the location where it occurs, and heat flux at the upper plate.

**6-62** Reconsider Prob. 6-61. Using the results of this problem, obtain a relation for the volumetric heat generation rate  $\dot{e}_{\text{gen}}$ , in  $\text{W/m}^3$ . Then express the convection problem as an equivalent conduction problem in the oil layer. Verify your model by solving the conduction problem and obtaining a relation for the maximum temperature, which should be identical to the one obtained in the convection analysis.

**6-63** A 6-cm-diameter shaft rotates at 3000 rpm in a 20-cm-long bearing with a uniform clearance of 0.2 mm. At steady operating conditions, both the bearing and the shaft in the vicinity of the oil gap are at  $50^\circ\text{C}$ , and the viscosity and thermal conductivity of lubricating oil are  $0.05 \text{ N}\cdot\text{s/m}^2$  and  $0.17 \text{ W/m}\cdot\text{K}$ . By simplifying and solving the continuity, momentum, and energy equations, determine (a) the maximum temperature of oil, (b) the rates of heat transfer to the bearing and the shaft, and (c) the mechanical power wasted by the viscous dissipation in the oil. *Answers: (a)  $53.3^\circ\text{C}$ , (b) 419 W, (c) 838 W*

FIGURE P6-63

**6-64** Repeat Prob. 6-63 by assuming the shaft to have reached peak temperature and thus heat transfer to the shaft to be negligible, and the bearing surface still to be maintained at  $50^\circ\text{C}$ .

**6-65** Reconsider Prob. 6-63. Using EES (or other) software, investigate the effect of shaft velocity on the mechanical power wasted by viscous dissipation. Let the shaft rotation vary from 0 rpm to 5000 rpm. Plot the power wasted versus the shaft rpm, and discuss the results.

**6-66** A 5-cm-diameter shaft rotates at 4500 rpm in a 15-cm-long, 8-cm-outer-diameter cast iron bearing ( $k = 70 \text{ W/m}\cdot\text{K}$ ) with a uniform clearance of 0.6 mm filled with lubricating oil ( $\mu = 0.03 \text{ N}\cdot\text{s/m}^2$  and  $k = 0.14 \text{ W/m}\cdot\text{K}$ ). The bearing is cooled externally by a liquid, and its outer surface is maintained at  $40^\circ\text{C}$ . Disregarding heat conduction through the shaft and assuming one-dimensional heat transfer, determine (a) the rate of heat transfer to the coolant, (b) the surface temperature of the shaft, and (c) the mechanical power wasted by the viscous dissipation in oil.

FIGURE P6-66

**6-67** Repeat Prob. 6-66 for a clearance of 1 mm.

**6-68E** Glycerin at  $50^\circ\text{F}$  is flowing over a flat plate at a free stream velocity of 6 ft/s. Determine the velocity and thermal boundary layer thicknesses at a distance of 0.5 ft from the leading edge. Also calculate the ratio of the velocity boundary thickness to the thermal boundary layer thickness for this flow and interpret the result.

**6-69** Water at  $20^\circ\text{C}$  is flowing with velocity of 0.5 m/s between two parallel flat plates placed 1 cm apart. Determine the distances from the entrance at which the velocity and thermal boundary layers meet.

FIGURE P6-69

**6-70E** Consider a laminar boundary layer flow over a flat plate. Determine the  $\delta/\delta_t$  ratios for air (at 1 atm), liquid water, isobutane, and engine oil, and mercury. Evaluate all properties at  $50^\circ\text{F}$ .

**6-71** For laminar boundary layers it is reasonable to expect that  $\delta/\delta_t \approx \text{Pr}^n$ , where  $n$  is a positive exponent. Consider laminar boundary layer flow over a flat plate with air at  $100^\circ\text{C}$  and 1 atm, the thermal boundary layer thickness is approximately 15% larger than the velocity boundary layer thickness. Determine the ratio of  $\delta/\delta_t$  if the fluid is engine oil (unused) under the same flow conditions.

**6-72** Air at  $15^\circ\text{C}$  and 1 atm is flowing over a 0.3-m-long plate at  $65^\circ\text{C}$  at velocity of 3.0 m/s. Using EES, Excel, or other software, plot the following on a combined graph for the range of  $x = 0.0 \text{ m}$  to  $x = x_{\text{cr}}$ .

- The hydrodynamic boundary layer as a function of  $x$ .
- The thermal boundary layer as a function of  $x$ .

**6-73** Liquid water at  $15^\circ\text{C}$  is flowing over a 0.3-m-wide plate at  $65^\circ\text{C}$  at a velocity of 3.0 m/s. Using EES, Excel, or other comparable software, plot (a) the hydrodynamic boundary layer and (b) the thermal boundary layer as a function of  $x$  on the same graph for the range of  $x = 0.0 \text{ m}$  to  $x = x_{\text{cr}}$ . Use a critical Reynolds number of 500,000.

**6-74**  Saturated liquid water at 5°C is flowing over a flat plate at a velocity of 1 m/s. Using EES (or other) software, determine the effect of the location along the plate ( $x$ ) on the velocity and thermal boundary layer thicknesses. By varying  $x$  for  $0 < x \leq 0.5$  m, plot the velocity and thermal boundary layer thicknesses as a function of  $x$ . Discuss the results.

**6-75**  Mercury at 0°C is flowing over a flat plate at a velocity of 0.1 m/s. Using EES (or other) software, determine the effect of the location along the plate ( $x$ ) on the velocity and thermal boundary layer thicknesses. By varying  $x$  for  $0 < x \leq 0.5$  m, plot the velocity and thermal boundary layer thicknesses as a function of  $x$ . Discuss the results.

**6-76**  Water vapor at 0°C and 1 atm is flowing over a flat plate at a velocity of 10 m/s. Using EES (or other) software, determine the effect of the location along the plate ( $x$ ) on the velocity and thermal boundary layer thicknesses. By varying  $x$  for  $0 < x \leq 0.5$  m, plot the velocity and thermal boundary layer thicknesses as a function of  $x$ . Discuss the results.

**6-77** Consider a laminar ideal gas flow over a flat plate, where the local Nusselt number can be expressed as  $Nu_x = 0.332Re_x^{1/2}Pr^{1/3}$ . Using the expression for the local Nusselt number, show that it can be rewritten in terms of local convection heat transfer coefficient as  $h_x = C[V/(xT)]^m$ , where  $C$  and  $m$  are constants.

**6-78** Consider air flowing over a 1-m-long flat plate at a velocity of 3 m/s. Determine the convection heat transfer coefficients and the Nusselt numbers at  $x = 0.5$  m and 0.75 m. Evaluate the air properties at 40°C and 1 atm.

**6-79**  Air with a temperature of 20°C is flowing over a flat plate ( $k = 15$  W/m·K) at a velocity of 3 m/s. The plate surface temperature is maintained at 60°C. Using EES (or other) software, determine the effect of the location along the plate ( $x$ ) on the heat transfer coefficient and the surface temperature gradient of the plate. By varying  $x$  for  $0 < x \leq 0.5$  m, plot the heat transfer coefficient and the surface temperature gradient of the plate as a function of  $x$ . Evaluate the air properties at 40°C and 1 atm.

**6-80** For laminar flow over a flat plate the local heat transfer coefficient varies as  $h_x = Cx^{-0.5}$ , where  $x$  is measured from the leading edge of the plate and  $C$  is a constant. Determine the ratio of the average convection heat transfer coefficient over the entire plate of length  $L$  to the local convection heat transfer coefficient at the end of the plate ( $x = L$ ).

**6-81E** An airfoil with a characteristic length of 0.2 ft is placed in airflow at 1 atm and 60°F with free stream velocity of 150 ft/s and convection heat transfer coefficient of 21 Btu/h·ft<sup>2</sup>·°F. If a second airfoil with a characteristic length of 0.4 ft is placed in the airflow at 1 atm and 60°F with free stream velocity of 75 ft/s, determine the heat flux from the second airfoil. Both airfoils are maintained at a constant surface temperature of 180°F.

FIGURE P6-81E

### Momentum and Heat Transfer Analogies

**6-82C** How is Reynolds analogy expressed? What is the value of it? What are its limitations?

**6-83C** How is the modified Reynolds analogy expressed? What is the value of it? What are its limitations?

**6-84** Consider an airplane cruising at an altitude of 10 km where standard atmospheric conditions are -50°C and 26.5 kPa at a speed of 800 km/h. Each wing of the airplane can be modeled as a 25-m × 3-m flat plate, and the friction coefficient of the wings is 0.0016. Using the momentum-heat transfer analogy, determine the heat transfer coefficient for the wings at cruising conditions. *Answer: 89.6 W/m<sup>2</sup>·K*

**6-85** A metallic airfoil of elliptical cross section has a mass of 50 kg, surface area of 12 m<sup>2</sup>, and a specific heat of 0.50 kJ/kg·K. The airfoil is subjected to air flow at 1 atm, 25°C, and 5 m/s along its 3-m-long side. The average temperature of the airfoil is observed to drop from 160°C to 150°C within 2 min of cooling. Assuming the surface temperature of the airfoil to be equal to its average temperature and using momentum-heat transfer analogy, determine the average friction coefficient of the airfoil surface. *Answer: 0.000363*

**6-86** Repeat Prob. 6-85 for an air-flow velocity of 10 m/s.

**6-87** The electrically heated 0.6-m-high and 1.8-m-long windshield of a car is subjected to parallel winds at 1 atm, 0°C, and 80 km/h. The electric power consumption is observed to be 50 W when the exposed surface temperature of the windshield is 4°C. Disregarding radiation and heat transfer from the inner surface and using the momentum-heat transfer analogy, determine drag force the wind exerts on the windshield.

**6-88**  A 5-m × 5-m flat plate maintained at a constant temperature of 80°C is subjected to parallel flow of air at 1 atm, 20°C, and 10 m/s. The total drag force acting on the upper surface of the plate is measured to be 2.4 N. Using momentum-heat transfer analogy, determine the average convection heat transfer coefficient, and the rate of heat transfer between the upper surface of the plate and the air.

**6-89** Air (1 atm, 5°C) with free stream velocity of 2 m/s flowing in parallel to a stationary thin 1 m × 1 m flat plate over the top and bottom surfaces. The flat plate has a uniform surface

temperature of 35°C. If the friction force asserted on the flat plate is 0.1 N, determine the rate of heat transfer from the plate. *Answer: 1862 W*

**FIGURE P6–89**

**6–90** Air at 1 atm and 20°C is flowing over the top surface of a 0.2 m × 0.5 m-thin metal foil. The air stream velocity is 100 m/s and the metal foil is heated electrically with a uniform heat flux of 6100 W/m<sup>2</sup>. If the friction force on the metal foil surface is 0.3 N, determine the surface temperature of the metal foil. Evaluate the fluid properties at 100°C.

**FIGURE P6–90**

**6–91** Air at 1 atm is flowing over a flat plate with a free stream velocity of 70 m/s. If the convection heat transfer coefficient can be correlated by  $Nu_x = 0.03 Re_x^{0.8} Pr^{1/3}$ , determine the friction coefficient and wall shear stress at a location 2 m from the leading edge. Evaluate fluid properties at 20°C.

**6–92** Metal plates are being cooled with air blowing in parallel over each plate. The average friction coefficient over each plate is given as  $C_f = 1.33(Re_L)^{-0.5}$  for  $Re_L < 5 \times 10^5$ . Each metal plate length parallel to the air flow is 1 m. Determine the average convection heat transfer coefficient for the plate, if the air velocity is 5 m/s. Evaluate the air properties at 20°C and 1 atm.

**6–93** A flat plate is subject to air flow parallel to its surface. The average friction coefficient over the plate is given as

$$C_f = 1.33(Re_L)^{-1/2} \quad \text{for } Re_L < 5 \times 10^5 \quad (\text{laminar flow})$$

$$C_f = 0.074(Re_L)^{-1/5} \quad \text{for } 5 \times 10^5 \leq Re_L \leq 10^7 \quad (\text{turbulent flow})$$

The plate length parallel to the air flow is 1 m. Using EES (or other) software, determine the effect of air velocity on the average convection heat transfer coefficient for the plate. By varying the air velocity for  $0 < V \leq 20$  m/s, plot the average convection heat transfer coefficient as a function of air velocity. Evaluate the air properties at 20°C and 1 atm.

### Special Topic: Microscale Heat Transfer

**6–94** Using a cylinder, a sphere, and a cube as examples, show that the rate of heat transfer is inversely proportional to the nominal size of the object. That is, heat transfer per unit area increases as the size of the object decreases.

**FIGURE P6–94**

**6–95** Determine the heat flux at the wall of a microchannel of width 1 μm if the wall temperature is 50°C and the average gas temperature near the wall is 100°C for the cases of

- (a)  $\sigma_T = 1.0$ ,  $\gamma = 1.667$ ,  $k = 0.15 \text{ W/m}\cdot\text{K}$ ,  $\lambda/\text{Pr} = 0.5$
- (b)  $\sigma_T = 0.8$ ,  $\gamma = 2$ ,  $k = 0.1 \text{ W/m}\cdot\text{K}$ ,  $\lambda/\text{Pr} = 5$

**6–96** If  $(\partial T/\partial y)_w = 80 \text{ K/m}$ , calculate the Nusselt number for a microchannel of width 1.2 μm if the wall temperature is 50°C and it is surrounded by (a) ambient air at temperature 30°C, (b) nitrogen gas at temperature –100°C.

### Review Problems

**6–97E** Evaluate the Prandtl number from the following data:  $c_p = 0.5 \text{ Btu/lbm}\cdot\text{R}$ ,  $k = 2 \text{ Btu/h}\cdot\text{ft}\cdot\text{R}$ ,  $\mu = 0.3 \text{ lbm/ft}\cdot\text{s}$ .

**6–98** A fluid flows at 5 m/s over a wide flat plate 15 cm long. For each from the following list, calculate the Reynolds number at the downstream end of the plate. Indicate whether the flow at that point is laminar or turbulent. Assume all fluids are at 50°C. (a) Air, (b) CO<sub>2</sub>, (c) Water, (d) Engine oil (unused).

**6–99E** Consider a fluid flowing over a flat plate at a constant free stream velocity. The critical Reynolds number is  $5 \times 10^5$  and the distance from the leading edge at which the transition from laminar to turbulent flow occurs is  $x_{cr} = 7 \text{ ft}$ . Determine the characteristic length ( $L_c$ ) at which the Reynolds number is  $1 \times 10^5$ .

**6–100** Consider the Couette flow of a fluid with a viscosity of  $\mu = 0.8 \text{ N}\cdot\text{s}/\text{m}^2$  and thermal conductivity of  $k_f = 0.145 \text{ W/m}\cdot\text{K}$ . The lower plate is stationary and made of a material of thermal conductivity  $k_p = 1.5 \text{ W/m}\cdot\text{K}$  and thickness  $b = 3 \text{ mm}$ . Its outer surface is maintained at  $T_s = 40^\circ\text{C}$ . The upper plate is insulated and moves with a uniform speed  $V = 5 \text{ m/s}$ . The distance between plates is  $L = 5 \text{ mm}$ .

- (a) Sketch the temperature distribution,  $T(y)$ , in the fluid and in the stationary plate.
- (b) Determine the temperature distribution function,  $T(y)$ , in the fluid ( $0 < y < L$ ).

- (c) Calculate the maximum temperature of the fluid, as well as the temperature of the fluid at the contact surfaces with the lower and upper plates.

FIGURE P6–100

is 3 m/s and the shear stress of the circuit board surface is 0.075 N/m<sup>2</sup>, determine the temperature difference between the circuit board surface temperature and the airstream temperature. Evaluate the fluid properties at 40°C.

FIGURE P6–105

- 6–101** Engine oil at 15°C is flowing over a 0.3-m-wide plate at 65°C at a velocity of 3.0 m/s. Using EES, Excel, or other comparable software, plot (a) the hydrodynamic boundary layer and (b) the thermal boundary layer as a function of  $x$  on the same graph for the range of  $x = 0.0$  m to  $x = x_{cr}$ . Use a critical Reynolds number of 500,000.

- 6–102** Object 1 with a characteristic length of 0.5 m is placed in airflow at 1 atm and 20°C with free stream velocity of 50 m/s. The heat flux transfer from object 1 when placed in the airflow is measured to be 12,000 W/m<sup>2</sup>. If object 2 has the same shape and geometry as object 1 (but with a characteristic length of 5 m) is placed in the airflow at 1 atm and 20°C with free stream velocity of 5 m/s, determine the average convection heat transfer coefficient for object 2. Both objects are maintained at a constant surface temperature of 120°C.

- 6–103** A rectangular bar with a characteristic length of 0.5 m is placed in a free stream flow where the convection heat transfer coefficients were found to be 100 W/m<sup>2</sup>·K and 50 W/m<sup>2</sup>·K when the free stream velocities were 25 m/s and 5 m/s, respectively. If the Nusselt number can be expressed as  $\text{Nu} = C \text{Re}^m \text{Pr}^n$ , where  $C$ ,  $m$ , and  $n$  are constants, determine the convection heat transfer coefficients for similar bars with (a)  $L = 1$  m and  $V = 5$  m/s, and (b)  $L = 2$  m and  $V = 50$  m/s.

- 6–104** In an effort to prevent the formation of ice on the surface of a wing, electrical heaters are embedded inside the wing. With a characteristic length of 2.5 m, the wing has a friction coefficient of 0.001. If the wing is moving at a speed of 200 m/s through air at 1 atm and -20°C, determine the heat flux necessary to keep the wing surface above 0°C. Evaluate fluid properties at -10°C.

- 6–105** A 15 cm × 20 cm circuit board is being cooled by forced convection of air at 1 atm. The heat from the circuit board is estimated to be 1000 W/m<sup>2</sup>. If the air stream velocity

#### Fundamentals of Engineering (FE) Exam Problems

- 6–106** The transition from laminar flow to turbulent flow in a forced convection situation is determined by which one of the following dimensionless numbers?

- (a) Grasshof   (b) Nusselt   (c) Reynolds  
(d) Stanton   (e) Mach

- 6–107** The \_\_\_\_\_ number is a significant dimensionless parameter for forced convection and the \_\_\_\_\_ number is a significant dimensionless parameter for natural convection.

- (a) Reynolds, Grashof   (b) Reynolds, Mach  
(c) Reynolds, Eckert   (d) Reynolds, Schmidt  
(e) Grashof, Sherwood

- 6–108** In any forced or natural convection situation, the velocity of the flowing fluid is zero where the fluid wets any stationary surface. The magnitude of heat flux where the fluid wets a stationary surface is given by

(a)  $k(T_{\text{fluid}} - T_{\text{wall}})$    (b)  $k \frac{dT}{dy}\Big|_{\text{wall}}$

(c)  $k \frac{d^2T}{dy^2}\Big|_{\text{wall}}$    (d)  $h \frac{dT}{dy}\Big|_{\text{wall}}$

- (e) None of them

- 6–109** The coefficient of friction  $C_f$  for a fluid flowing across a surface in terms of the surface shear stress,  $\tau_s$ , is given by

- (a)  $2PV^2/\tau_w$    (b)  $2\tau_w/\rho V^2$    (c)  $2\tau_w/\rho V^2 \Delta T$   
(d)  $4\tau_w/\rho V^2$    (e) None of them

- 6–110** Most correlations for the convection heat transfer coefficient use the dimensionless Nusselt number, which is defined as

- (a)  $h/k$    (b)  $k/h$    (c)  $hL_c/k$   
(d)  $kL_c/h$    (e)  $k/\rho c_p$

**6–111** For the same initial conditions, one can expect the laminar thermal and momentum boundary layers on a flat plate to have the same thickness when the Prandtl number of the flowing fluid is

- (a) Close to zero    (b) Small    (c) Approximately one
- (d) Large    (e) Very large

**6–112** One can expect the heat transfer coefficient for turbulent flow to be \_\_\_\_\_ for laminar flow.

- (a) less than    (b) same as    (c) greater than

**6–113** An electrical water ( $k = 0.61 \text{ W/m}\cdot\text{K}$ ) heater uses natural convection to transfer heat from a 1-cm-diameter by 0.65-m-long, 110 V electrical resistance heater to the water. During operation, the surface temperature of this heater is 120°C while the temperature of the water is 35°C, and the Nusselt number (based on the diameter) is 5. Considering only the side surface of the heater (and thus  $A = \pi DL$ ), the current passing through the electrical heating element is

- (a) 2.2 A    (b) 2.7 A    (c) 3.6 A    (d) 4.8 A    (e) 5.6 A

**6–114** In turbulent flow, one can estimate the Nusselt number using the analogy between heat and momentum transfer (Colburn analogy). This analogy relates the Nusselt number to the coefficient of friction,  $C_f$ , as

- (a)  $\text{Nu} = 0.5 C_f \text{Re} \text{Pr}^{1/3}$     (b)  $\text{Nu} = 0.5 C_f \text{Re} \text{Pr}^{2/3}$
- (c)  $\text{Nu} = C_f \text{Re} \text{Pr}^{1/3}$     (d)  $\text{Nu} = C_f \text{Re} \text{Pr}^{2/3}$

### Design and Essay Problems

**6–115** Design an experiment to measure the viscosity of liquids using a vertical funnel with a cylindrical reservoir of height  $h$  and a narrow flow section of diameter  $D$  and length  $L$ . Making appropriate assumptions, obtain a relation for viscosity in terms of easily measurable quantities such as density and volume flow rate.

**6–116** A facility is equipped with a wind tunnel, and can measure the friction coefficient for flat surfaces and airfoils. Design an experiment to determine the mean heat transfer coefficient for a surface using friction coefficient data.

# EXTERNAL FORCED CONVECTION

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Distinguish between internal and external flow,
- Develop an intuitive understanding of friction drag and pressure drag, and evaluate the average drag and convection coefficients in external flow,
- Evaluate the drag and heat transfer associated with flow over a flat plate for both laminar and turbulent flow,
- Calculate the drag force exerted on cylinders and spheres during cross flow, and the average heat transfer coefficient, and
- Determine the pressure drop and the average heat transfer coefficient associated with flow across a tube bank for both in-line and staggered configurations.

In Chapter 6, we considered the general and theoretical aspects of forced convection, with emphasis on differential formulation and analytical solutions. In this chapter, we consider the practical aspects of forced convection to or from flat or curved surfaces subjected to *external flow*, characterized by the freely growing boundary layers surrounded by a free flow region that involves no velocity and temperature gradients.

We start this chapter with an overview of external flow, with emphasis on friction and pressure drag, flow separation, and the evaluation of average drag and convection coefficients. We continue with *parallel flow over flat plates*. In Chapter 6, we solved the boundary layer equations for steady, laminar, parallel flow over a flat plate, and obtained relations for the local friction coefficient and the Nusselt number. Using these relations as the starting point, we determine the average friction coefficient and Nusselt number. We then extend the analysis to turbulent flow over flat plates with and without an unheated starting length.

Next, we consider *cross flow over cylinders and spheres*, and present graphs and empirical correlations for the drag coefficients and the Nusselt numbers, and discuss their significance. Finally, we consider *cross flow over tube banks* in aligned and staggered configurations, and present correlations for the pressure drop and the average Nusselt number for both configurations.

## 7–1 ■ DRAG AND HEAT TRANSFER IN EXTERNAL FLOW

Fluid flow over solid bodies frequently occurs in practice, and it is responsible for numerous physical phenomena such as the *drag force* acting on the automobiles, power lines, trees, and underwater pipelines; the *lift* developed by airplane wings; *upward draft* of rain, snow, hail, and dust particles in high winds; and the *cooling* of metal or plastic sheets, steam and hot water pipes, and extruded wires (Fig. 7–1). Therefore, developing a good understanding of external flow and external forced convection is important in the mechanical and thermal design of many engineering systems such as aircraft, automobiles, buildings, electronic components, and turbine blades.

The flow fields and geometries for most external flow problems are too complicated to be solved analytically, and thus we have to rely on correlations based on experimental data. The availability of high-speed computers has made it possible to conduct series of “numerical experimentations” quickly by solving the governing equations numerically, and to resort to the expensive and time-consuming testing and experimentation only in the final stages of design. In this chapter, we mostly rely on relations developed experimentally.

The velocity of the fluid relative to an immersed solid body sufficiently far from the body (outside the boundary layer) is called the **free-stream velocity**. It is usually taken to be equal to the **upstream velocity  $V$** , also called the **approach velocity**, which is the velocity of the approaching fluid far ahead of the body. This idealization is nearly exact for very thin bodies, such as a flat plate parallel to flow, but approximate for blunt bodies such as a large cylinder. The fluid velocity ranges from zero at the surface (the no-slip condition) to the free-stream value away from the surface, and the subscript “infinity” serves as a reminder that this is the value at a distance where the presence of the body is not felt. The upstream velocity, in general, may vary with location and time (e.g., the wind blowing past a building). But in the design and analysis, the upstream velocity is usually assumed to be *uniform* and *steady* for convenience, and this is what we will do in this chapter.

### Friction and Pressure Drag

It is common experience that a body meets some resistance when it is forced to move through a fluid, especially a liquid. You may have seen high winds knocking down trees, power lines, and even trailers, and have felt the strong “push” the wind exerts on your body. You experience the same feeling when you extend your arm out of the window of a moving car. The force a flowing fluid exerts on a body in the flow direction is called **drag** (Fig. 7–2).

A stationary fluid exerts only normal pressure forces on the surface of a body immersed in it. A moving fluid, however, also exerts tangential shear forces on the surface because of the no-slip condition caused by viscous effects. Both of these forces, in general, have components in the direction of flow, and thus the drag force is due to the combined effects of pressure and wall shear forces in the flow direction. The components of the pressure and wall shear forces in the *normal* direction to flow tend to move the body in that direction, and their sum is called **lift**.

In general, both the skin friction (wall shear) and pressure contribute to the drag and the lift. In the special case of a thin flat plate aligned parallel to the flow direction, the drag force depends on the wall shear only and is independent

**FIGURE 7–1**

Flow over bodies is commonly encountered in practice.

**FIGURE 7–2**

Schematic for measuring the drag force acting on a car in a wind tunnel.

FIGURE 7-3

(a) Drag force acting on a flat plate parallel to the flow depends on wall shear only. (b) Drag force acting on a flat plate normal to the flow depends on the pressure only and is independent of the wall shear, which acts normal to the free-stream flow.

of pressure. When the flat plate is placed normal to the flow direction, however, the drag force depends on the pressure only and is independent of the wall shear since the shear stress in this case acts in the direction normal to flow (Fig. 7-3). For slender bodies such as wings, the shear force acts nearly parallel to the flow direction. The drag force for such slender bodies is mostly due to shear forces (the skin friction).

The drag force  $F_D$  depends on the density  $\rho$  of the fluid, the upstream velocity  $V$ , and the size, shape, and orientation of the body, among other things. The drag characteristics of a body is represented by the dimensionless **drag coefficient**  $C_D$  defined as

$$\text{Drag coefficient:} \quad C_D = \frac{F_D}{\frac{1}{2}\rho V^2 A} \quad (7-1)$$

where  $A$  is the *frontal area* (the area projected on a plane normal to the direction of flow) for blunt bodies—bodies that tend to block the flow. The frontal area of a cylinder of diameter  $D$  and length  $L$ , for example, is  $A = LD$ . For parallel flow over flat plates or thin airfoils,  $A$  is the surface area. The drag coefficient is primarily a function of the shape of the body, but it may also depend on the Reynolds number and the surface roughness.

The drag force is the net force exerted by a fluid on a body in the direction of flow due to the combined effects of wall shear and pressure forces. The part of drag that is due directly to wall shear stress  $\tau_w$  is called the **skin friction drag** (or just *friction drag*) since it is caused by frictional effects, and the part that is due directly to pressure  $P$  is called the **pressure drag** (also called the *form drag* because of its strong dependence on the form or shape of the body). When the friction and pressure drag coefficients are available, the total drag coefficient is determined by simply adding them,

$$C_D + C_{D, \text{friction}} + C_{D, \text{pressure}} \quad (7-2)$$

The *friction drag* is the component of the wall shear force in the direction of flow, and thus it depends on the orientation of the body as well as the magnitude of the wall shear stress  $\tau_w$ . The friction drag is *zero* for a surface normal to flow, and *maximum* for a surface parallel to flow since the friction drag in this case equals the total shear force on the surface. Therefore, for parallel flow over a flat plate, the drag coefficient is equal to the *friction drag coefficient*, or simply the *friction coefficient* (Fig. 7-4). That is,

$$\text{Flat plate:} \quad C_D = C_{D, \text{friction}} = C_f \quad (7-3)$$

Once the average friction coefficient  $C_f$  is available, the drag (or friction) force over the surface can be determined from Eq. 7-1. In this case,  $A$  is the surface area of the plate exposed to fluid flow. When both sides of a thin plate are subjected to flow,  $A$  becomes the total area of the top and bottom surfaces. Note that the friction coefficient, in general, varies with location along the surface.

Friction drag is a strong function of viscosity, and an “idealized” fluid with zero viscosity would produce zero friction drag since the wall shear stress would be zero. The pressure drag would also be zero in this case during steady flow regardless of the shape of the body since there are no pressure losses. For flow in the horizontal direction, for example, the pressure along a horizontal

FIGURE 7-4

For parallel flow over a flat plate, the pressure drag is zero, and thus the drag coefficient is equal to the friction coefficient and the drag force is equal to the friction force.

line is constant (just like stationary fluids) since the upstream velocity is constant, and thus there is no net pressure force acting on the body in the horizontal direction. Therefore, the total drag is zero for the case of ideal inviscid fluid flow.

At low Reynolds numbers, most drag is due to friction drag. This is especially the case for highly streamlined bodies such as airfoils. The friction drag is also proportional to the surface area. Therefore, bodies with a larger surface area experience a larger friction drag. Large commercial airplanes, for example, reduce their total surface area and thus drag by retracting their wing extensions when they reach the cruising altitudes to save fuel. The friction drag coefficient is independent of *surface roughness* in laminar flow, but is a strong function of surface roughness in turbulent flow due to surface roughness elements protruding further into the boundary layer.

The pressure drag is proportional to the frontal area and to the *difference* between the pressures acting on the front and back of the immersed body. Therefore, the pressure drag is usually dominant for blunt bodies, negligible for streamlined bodies such as airfoils, and zero for thin flat plates parallel to the flow.

When a fluid separates from a body, it forms a separated region between the body and the fluid stream. This low-pressure region behind the body where recirculating and backflows occur is called the **separated region**. The larger the separated region, the larger the pressure drag. The effects of flow separation are felt far downstream in the form of reduced velocity (relative to the upstream velocity). The region of flow trailing the body where the effects of the body on velocity are felt is called the **wake** (Fig. 7–5). The separated region comes to an end when the two flow streams reattach. Therefore, the separated region is an enclosed volume, whereas the wake keeps growing behind the body until the fluid in the wake region regains its velocity and the velocity profile becomes nearly flat again. Viscous and rotational effects are the most significant in the boundary layer, the separated region, and the wake.

**FIGURE 7–5**

Separation during flow over a tennis ball and the wake region.

## Heat Transfer

The phenomena that affect drag force also affect heat transfer, and this effect appears in the Nusselt number. By nondimensionalizing the boundary layer equations, it was shown in Chapter 6 that the local and average Nusselt numbers have the functional form

$$\text{Nu}_x = f_1(x^*, \text{Re}_x, \text{Pr}) \quad \text{and} \quad \text{Nu} = f_2(\text{Re}_L, \text{Pr}) \quad (7-4a, b)$$

The experimental data for heat transfer is often represented conveniently with reasonable accuracy by a simple power-law relation of the form

$$\text{Nu} = C \text{Re}_L^m \text{Pr}^n \quad (7-5)$$

where  $m$  and  $n$  are constant exponents, and the value of the constant  $C$  depends on geometry and flow.

The fluid temperature in the thermal boundary layer varies from  $T_s$  at the surface to about  $T_\infty$  at the outer edge of the boundary. The fluid properties also

vary with temperature, and thus with position across the boundary layer. In order to account for the variation of the properties with temperature, the fluid properties are usually evaluated at the so-called **film temperature**, defined as

$$T_f = \frac{T_s + T_\infty}{2} \quad (7-6)$$

which is the *arithmetic average* of the surface and the free-stream temperatures. The fluid properties are then assumed to remain constant at those values during the entire flow. An alternative way of accounting for the variation of properties with temperature is to evaluate all properties at the free stream temperature and to multiply the Nusselt number relation in Eq. 7-5 by  $(Pr_\infty/Pr_s)^r$  or  $(\mu_\infty/\mu_s)^r$  where  $r$  is an experimentally determined constant.

The local drag and convection coefficients vary along the surface as a result of the changes in the velocity boundary layers in the flow direction. We are usually interested in the drag force and the heat transfer rate for the *entire* surface, which can be determined using the *average* friction and convection coefficient. Therefore, we present correlations for both local (identified with the subscript  $x$ ) and average friction and convection coefficients. When relations for local friction and convection coefficients are available, the *average* friction and convection coefficients for the entire surface can be determined by integration from

$$C_f = \frac{1}{L} \int_0^L C_{f,x} dx \quad (7-7)$$

and

$$h = \frac{1}{L} \int_0^L h_x dx \quad (7-8)$$

When the average drag and convection coefficients are available, the drag force can be determined from Eq. 7-1 and the rate of heat transfer to or from an isothermal surface can be determined from

$$\dot{Q} = h A_s (T_s - T_\infty) \quad (7-9)$$

where  $A_s$  is the surface area.

## 7-2 • PARALLEL FLOW OVER FLAT PLATES

Consider the parallel flow of a fluid over a flat plate of length  $L$  in the flow direction, as shown in Fig. 7-6. The  $x$ -coordinate is measured along the plate surface from the leading edge in the direction of the flow. The fluid approaches the plate in the  $x$ -direction with a uniform velocity  $V$  and temperature  $T_\infty$ . The flow in the velocity boundary layers starts out as laminar, but if the plate is sufficiently long, the flow becomes turbulent at a distance  $x_{cr}$  from the leading edge where the Reynolds number reaches its critical value for transition.

The transition from laminar to turbulent flow depends on the *surface geometry*, *surface roughness*, *upstream velocity*, *surface temperature*, and the *type of fluid*, among other things, and is best characterized by the Reynolds number.

**FIGURE 7-6**

Laminar and turbulent regions of the boundary layer during flow over a flat plate.

The Reynolds number at a distance  $x$  from the leading edge of a flat plate is expressed as

$$\text{Re}_x = \frac{\rho Vx}{\mu} = \frac{Vx}{\nu} \quad (7-10)$$

Note that the value of the Reynolds number varies for a flat plate along the flow, reaching  $\text{Re}_L = VL/\nu$  at the end of the plate.

For flow over a flat plate, transition from laminar to turbulent begins at about  $\text{Re} \approx 1 \times 10^5$ , but does not become fully turbulent before the Reynolds number reaches much higher values, typically around  $3 \times 10^6$ . In engineering analysis, a generally accepted value for the critical Reynold number is

$$\text{Re}_{\text{cr}} = \frac{\rho Vx_{\text{cr}}}{\mu} = 5 \times 10^5 \quad (7-11)$$

The actual value of the engineering critical Reynolds number for a flat plate may vary somewhat from  $10^5$  to  $3 \times 10^6$ , depending on the surface roughness, the turbulence level, and the variation of pressure along the surface.

## Friction Coefficient

Based on analysis, the boundary layer thickness and the local friction coefficient at location  $x$  for laminar flow over a flat plate were determined in Chapter 6 to be

$$\text{Laminar: } \delta = \frac{4.91x}{\text{Re}_x^{1/2}} \quad \text{and} \quad C_{f,x} = \frac{0.664}{\text{Re}_x^{1/2}}, \quad \text{Re}_x < 5 \times 10^5 \quad (7-12a, b)$$

From experiments the corresponding relations for turbulent flow are

$$\text{Turbulent: } \delta = \frac{0.38x}{\text{Re}_x^{1/5}} \quad \text{and} \quad C_{f,x} = \frac{0.059}{\text{Re}_x^{1/5}}, \quad 5 \times 10^5 \leq \text{Re}_x \leq 10^7 \quad (7-13a, b)$$

where  $x$  is the distance from the leading edge of the plate and  $\text{Re}_x = Vx/\nu$  is the Reynolds number at location  $x$ . Note that  $C_{f,x}$  is proportional to  $\text{Re}_x^{-1/2}$  and thus to  $x^{-1/2}$  for laminar flow. Therefore,  $C_{f,x}$  is supposedly *infinite* at the leading edge ( $x = 0$ ) and decreases by a factor of  $x^{-1/2}$  in the flow direction. The local friction coefficients are higher in turbulent flow than they are in laminar flow because of the intense mixing that occurs in the turbulent boundary layer. Note that  $C_{f,x}$  reaches its highest values when the flow becomes fully turbulent, and then decreases by a factor of  $x^{-1/5}$  in the flow direction.

The *average* friction coefficient over the entire plate is determined by substituting the relations above into Eq. 7-7 and performing the integrations (Fig. 7-7). We get

$$\text{Laminar: } C_f = \frac{1.33}{\text{Re}_L^{1/2}} \quad \text{Re}_L < 5 \times 10^5 \quad (7-14)$$

$$\text{Turbulent: } C_f = \frac{0.074}{\text{Re}_L^{1/5}} \quad 5 \times 10^5 \leq \text{Re}_L \leq 10^7 \quad (7-15)$$

The first relation gives the average friction coefficient for the entire plate when the flow is *laminar* over the *entire* plate. Note that the average friction coefficient over the entire plate in case of laminar flow is twice the value of local friction coefficient at the end of the plate,  $C_f = 2C_{f,x=L}$ . The second relation gives the average friction coefficient for the entire plate only when

|         |  |
|---------|--|
| $\circ$ |  |
| $\circ$ | $C_f = \frac{1}{L} \int_0^L C_{f,x} dx$  |

| $\circ$ |  |

FIGURE 7-7

The average friction coefficient over a surface is determined by integrating the local friction coefficient over the entire surface. The values shown here are for a laminar flat plate boundary layer.

the flow is *turbulent* over the *entire* plate, or when the laminar flow region of the plate is too small relative to the turbulent flow region (that is,  $x_{cr} \ll L$ ).

In some cases, a flat plate is sufficiently long for the flow to become turbulent, but not long enough to disregard the laminar flow region. In such cases, the *average* friction coefficient over the entire plate is determined by performing the integration in Eq. 7–7 over two parts: use Eq. 7–12b for the laminar region  $0 \leq x \leq x_{cr}$  and Eq. 7–13b for the turbulent region  $x_{cr} < x \leq L$  as

$$C_f = \frac{1}{L} \left( \int_0^{x_{cr}} C_{f,x} \text{ laminar } dx + \int_{x_{cr}}^L C_{f,x} \text{ turbulent } dx \right) \quad (7-16)$$

Note that we included the transition region with the turbulent region. Again taking the critical Reynolds number to be  $Re_{cr} = 5 \times 10^5$  and performing the integrations of Eq. 7–16 after substituting the indicated expressions, the *average* friction coefficient over the entire plate is determined to be

$$C_f = \frac{0.074}{Re_L^{1/5}} - \frac{1742}{Re_L} \quad 5 \times 10^5 \leq Re_L \leq 10^7 \quad (7-17)$$

For a completely turbulent boundary layer ( $Re_{cr} = 0$ ) or a very short  $x_{cr}$  ( $L \gg x_{cr}$  or  $Re_L \gg Re_{cr}$ ), Eq. 7–17 simplifies to the equation for turbulent flow, Eq. 7–15. For a completely turbulent boundary layer ( $Re_{cr} = 0$ ) or a very short  $x_{cr}$  ( $L \gg x_{cr}$  or  $Re_L \gg Re_{cr}$ ), Eq. 7–17 simplifies to the equation for turbulent flow, Eq. 7–15. The constants in Eq. 7–17 will be different for different critical Reynolds numbers. Also, the surfaces are assumed to be *smooth*, and the free stream to be *turbulent free*. For laminar flow, the friction coefficient depends on only the Reynolds number, and the surface roughness has no effect. For turbulent flow, however, surface roughness causes the friction coefficient to increase severalfold, to the point that in fully turbulent regime the friction coefficient is a function of surface roughness alone, and independent of the Reynolds number (Fig. 7–8). This is also the case in pipe flow.

A curve fit of experimental data for the average friction coefficient in this regime is given by Schlichting (1979) as

$$\text{Rough surface, turbulent: } C_f = \left( 1.89 - 1.62 \log \frac{\varepsilon}{L} \right)^{-2.5} \quad (7-18)$$

where  $\varepsilon$  is the surface roughness, and  $L$  is the length of the plate in the flow direction. In the absence of a better relation, the relation above can be used for turbulent flow on rough surfaces for  $Re > 10^6$ , especially when  $\varepsilon/L > 10^{-4}$ .

## Heat Transfer Coefficient

The local Nusselt number at a location  $x$  for laminar flow over a flat plate was determined in Chapter 6 by solving the differential energy equation to be

$$\text{Laminar: } Nu_x = \frac{h_x x}{k} = 0.332 Re_x^{0.5} Pr^{1/3} \quad Pr > 0.6, \quad Re_x < 5 \times 10^5 \quad (7-19)$$

From experiments the corresponding relation for turbulent flow is

$$\text{Turbulent: } Nu_x = \frac{h_x x}{k} = 0.0296 Re_x^{0.8} Pr^{1/3} \quad \begin{array}{l} 0.6 \leq Pr \leq 60 \\ 5 \times 10^5 \leq Re_x \leq 10^7 \end{array} \quad (7-20)$$

Note that  $h_x$  is proportional to  $Re_x^{0.5}$  and thus to  $x^{-0.5}$  for laminar flow. Therefore,  $h_x$  is *infinite* at the leading edge ( $x = 0$ ) and decreases by a factor of  $x^{-0.5}$  in

FIGURE 7–8

For turbulent flow, surface roughness may cause the friction coefficient to increase severalfold.

the flow direction. The variation of the boundary layer thickness  $\delta$  and the friction and heat transfer coefficients along an isothermal flat plate are shown in Fig. 7–9. The local friction and heat transfer coefficients are higher in turbulent flow than they are in laminar flow. Also,  $h_x$  reaches its highest values when the flow becomes fully turbulent, and then decreases by a factor of  $x^{-0.2}$  in the flow direction, as shown in the figure.

The *average* Nusselt number over the entire plate is determined by substituting the relations above into Eq. 7–8 and performing the integrations. We get

$$\text{Laminar: } \text{Nu} = \frac{hL}{k} = 0.664 \text{Re}_L^{0.5} \text{Pr}^{1/3} \quad \text{Re}_L < 5 \times 10^5, \text{Pr} > 0.6 \quad (7-21)$$

$$\text{Turbulent: } \text{Nu} = \frac{hL}{k} = 0.037 \text{Re}_L^{0.8} \text{Pr}^{1/3} \quad 0.6 \leq \text{Pr} \leq 60 \quad 5 \times 10^5 \leq \text{Re}_L \leq 10^7 \quad (7-22)$$

The first relation gives the average heat transfer coefficient for the entire plate when the flow is *laminar* over the *entire* plate. Note that the average Nusselt number over the entire plate in case of laminar flow is twice the value of local Nusselt number at the end to the plate,  $\text{Nu} = 2\text{Nu}_{x=L}$  or  $h = 2h_{x=L}$ . This is only true for laminar flow and does not carry over to the turbulent flow. The second relation gives the average heat transfer coefficient for the entire plate only when the flow is *turbulent* over the *entire* plate, or when the laminar flow region of the plate is too small relative to the turbulent flow region.

In some cases, a flat plate is sufficiently long for the flow to become turbulent, but not long enough to disregard the laminar flow region. In such cases, the *average* heat transfer coefficient over the entire plate is determined by performing the integration in Eq. 7–8 over two parts: use Eq. 7–21 for the laminar region  $0 \leq x \leq x_{cr}$  and Eq. 7–22 for the turbulent region  $x_{cr} \leq x \leq L$  as

$$h = \frac{1}{L} \left( \int_0^{x_{cr}} h_{x,\text{laminar}} dx + \int_{x_{cr}}^L h_{x,\text{turbulent}} dx \right) \quad (7-23)$$

Again taking the critical Reynolds number to be  $\text{Re}_{cr} = 5 \times 10^5$  and performing the integrations in Eq. 7–23 after substituting the indicated expressions, the *average* Nusselt number over the *entire* plate is determined to be (Fig. 7–10)

$$\text{Nu} = \frac{hL}{k} = (0.037 \text{Re}_L^{0.8} - 871) \text{Pr}^{1/3} \quad 0.6 \leq \text{Pr} \leq 60 \quad 5 \times 10^5 \leq \text{Re}_L \leq 10^7 \quad (7-24)$$

For a completely turbulent boundary layer ( $\text{Re}_{cr} = 0$ ) or a very short  $x_{cr}$  ( $L \gg x_{cr}$  or  $\text{Re}_L \gg \text{Re}_{cr}$ ), Eq. 7–24 simplifies to the equation for turbulent flow, Eq. 7–22. The constants in Eq. 7–24 will be different for different critical Reynolds numbers.

*Liquid metals* such as mercury have high thermal conductivities, and are commonly used in applications that require high heat transfer rates. However, they have very small Prandtl numbers, and thus the thermal boundary layer develops much faster than the velocity boundary layer. Then we can assume the velocity in the thermal boundary layer to be constant at the free stream value and solve the energy equation. It gives

$$\text{Nu}_x = 0.565(\text{Pe}_x \text{Pr})^{1/2} = 0.565 \text{Pe}_x^{1/2} \quad \text{Pr} \leq 0.05, \text{Pe}_x \geq 100 \quad (7-25)$$

where  $\text{Pe}_x = \text{Re}_x \text{Pr}$  is the dimensionless **Peclet number** (Fig. 7–11).

FIGURE 7-9

The variation of the local friction and heat transfer coefficients for flow over a flat plate.

FIGURE 7-10

Graphical representation of the average heat transfer coefficient for a flat plate with combined laminar and turbulent flow.

**FIGURE 7-11**

**Jean Claude Eugène Peclet** (1793–1857), a French physicist, was born in Besançon, France. He was one of the first scholars of the Ecole Normale at Paris. His publications were famous for their clarity of style, sharp minded views and well performed experiments. The dimensionless **Peclet number** is named after him.

*École Centrale Paris.*

**FIGURE 7-12**

Flow over a flat plate with an unheated starting length.

It is desirable to have a single correlation that applies to *all fluids*, including liquid metals. By curve-fitting existing data, Churchill and Ozoe (1973) proposed the following relation which is applicable for *all Prandtl numbers* and is claimed to be accurate to  $\pm 1\%$ ,

$$\text{Nu}_x = \frac{h_x}{k} = \frac{0.3387 \text{Pr}^{1/3} \text{Re}_x^{1/2}}{[1 + (0.0468/\text{Pr})^{2/3}]^{1/4}} \quad \text{Re}_x \text{Pr} \geq 100 \quad (7-26)$$

These relations have been obtained for the case of *isothermal* surfaces but could also be used approximately for the case of nonisothermal surfaces by assuming the surface temperature to be constant at some average value. Also, the surfaces are assumed to be *smooth*, and the free stream to be *turbulent free*. The effect of variable properties can be accounted for by evaluating all properties at the film temperature.

## Flat Plate with Unheated Starting Length

So far we have limited our consideration to situations for which the entire plate is heated from the leading edge. But many practical applications involve surfaces with an unheated starting section of length  $\xi$ , shown in Fig. 7-12, and thus there is no heat transfer for  $0 < x < \xi$ . In such cases, the velocity boundary layer starts to develop at the leading edge ( $x = 0$ ), but the thermal boundary layer starts to develop where heating starts ( $x = \xi$ ).

Consider a flat plate whose heated section is maintained at a constant temperature ( $T = T_s$  constant for  $x > \xi$ ). Using integral solution methods (see Kays and Crawford, 1994), the local Nusselt numbers for both laminar and turbulent flows are determined to be

$$\text{Laminar: } \text{Nu}_x = \frac{\text{Nu}_x \text{ (for } \xi = 0)}{[1 - (\xi/x)^{3/4}]^{1/3}} = \frac{0.332 \text{Re}_x^{0.5} \text{Pr}^{1/3}}{[1 - (\xi/x)^{3/4}]^{1/3}} \quad (7-27)$$

$$\text{Turbulent: } \text{Nu}_x = \frac{\text{Nu}_x \text{ (for } \xi = 0)}{[1 - (\xi/x)^{9/10}]^{1/9}} = \frac{0.0296 \text{Re}_x^{0.8} \text{Pr}^{1/3}}{[1 - (\xi/x)^{9/10}]^{1/9}} \quad (7-28)$$

for  $x > \xi$ . Note that for  $\xi = 0$ , these  $\text{Nu}_x$  relations reduce to  $\text{Nu}_x$  (for  $\xi = 0$ ), which is the Nusselt number relation for a flat plate without an unheated starting length. Therefore, the terms in brackets in the denominator serve as correction factors for plates with unheated starting lengths.

The determination of the average Nusselt number for the heated section of a plate requires the integration of the local Nusselt number relations above, which cannot be done analytically. Therefore, integrations must be done numerically. The results of numerical integrations have been correlated for the average convection coefficients (Thomas, 1977) as

$$\text{Laminar: } h = \frac{2[1 - (\xi/L)^{3/4}]}{1 - \xi/L} h_{x=L} \quad (7-29)$$

$$\text{Turbulent: } h = \frac{5[1 - (\xi/L)^{9/10}]}{4(1 - \xi/L)} h_{x=L} \quad (7-30)$$

The first relation gives the average convection coefficient for the entire heated section of the plate when the flow is laminar over the entire plate. Note that for  $\xi = 0$  it reduces to  $h = 2h_{x=L}$ , as expected. The second relation gives the average

convection coefficient for the case of turbulent flow over the entire plate or when the laminar flow region is small relative to the turbulent region.

## Uniform Heat Flux

When a flat plate is subjected to *uniform heat flux* instead of uniform temperature, the local Nusselt number is given by

$$\text{Laminar: } \text{Nu}_x = 0.453 \text{Re}_x^{0.5} \text{Pr}^{1/3} \quad \text{Pr} > 0.6, \quad \text{Re}_x < 5 \times 10^5 \quad (7-31)$$

$$\text{Turbulent: } \text{Nu}_x = 0.0308 \text{Re}_x^{0.8} \text{Pr}^{1/3} \quad 0.6 \leq \text{Pr} \leq 60, \quad 5 \times 10^5 \leq \text{Re}_x \leq 10^7 \quad (7-32)$$

These relations give values that are 36 percent higher for laminar flow and 4 percent higher for turbulent flow relative to the isothermal plate case. When the plate involves an unheated starting length, the relations developed for the uniform surface temperature case can still be used provided that Eqs. 7–31 and 7–32 are used for  $\text{Nu}_{x(\text{for } \xi = 0)}$  in Eqs. 7–27 and 7–28, respectively.

When heat flux  $\dot{q}_s$  is prescribed, the rate of heat transfer to or from the plate and the surface temperature at a distance  $x$  are determined from

$$\dot{Q} = \dot{q}_s A_s \quad (7-33)$$

and

$$\dot{q}_s = h_x [T_s(x) - T_\infty] \rightarrow T_s(x) = T_\infty + \frac{\dot{q}_s}{h_x} \quad (7-34)$$

where  $A_s$  is the heat transfer surface area.

### EXAMPLE 7–1 Flow of Hot Oil over a Flat Plate

Engine oil at  $60^\circ\text{C}$  flows over the upper surface of a 5-m-long flat plate whose temperature is  $20^\circ\text{C}$  with a velocity of 2 m/s (Fig. 7–13). Determine the total drag force and the rate of heat transfer per unit width of the entire plate.

**SOLUTION** Engine oil flows over a flat plate. The total drag force and the rate of heat transfer per unit width of the plate are to be determined.

**Assumptions** 1 The flow is steady and incompressible. 2 The critical Reynolds number is  $\text{Re}_{cr} = 5 \times 10^5$ .

**Properties** The properties of engine oil at the film temperature of  $T_f = (T_s + T_\infty)/2 = (20 + 60)/2 = 40^\circ\text{C}$  are (Table A–13)

$$\rho = 876 \text{ kg/m}^3 \quad \text{Pr} = 2962$$

$$k = 0.1444 \text{ W/m}\cdot\text{K} \quad \nu = 2.485 \times 10^{-4} \text{ m}^2/\text{s}$$

**Analysis** Noting that  $L = 5 \text{ m}$ , the Reynolds number at the end of the plate is

$$\text{Re}_L = \frac{VL}{\nu} = \frac{(2 \text{ m/s})(5 \text{ m})}{2.485 \times 10^{-4} \text{ m}^2/\text{s}} = 4.024 \times 10^4$$

which is less than the critical Reynolds number. Thus we have *laminar flow* over the entire plate, and the average friction coefficient is

$$C_f = 1.33 \text{Re}_L^{-0.5} = 1.33 \times (4.024 \times 10^4)^{-0.5} = 0.00663$$

**FIGURE 7–13**  
Schematic for Example 7–1.

Noting that the pressure drag is zero and thus  $C_D = C_f$  for parallel flow over a flat plate, the drag force acting on the plate per unit width becomes

$$F_D = C_f A \frac{\rho V^2}{2} = 0.00663(5 \times 1 \text{ m}^2) \frac{(876 \text{ kg/m}^3)(2 \text{ m/s})^2}{2} \left( \frac{1 \text{ N}}{1 \text{ kg}\cdot\text{m/s}^2} \right) = 58.1 \text{ N}$$

The total drag force acting on the entire plate can be determined by multiplying the value obtained above by the width of the plate.

This force per unit width corresponds to the weight of a mass of about 6 kg. Therefore, a person who applies an equal and opposite force to the plate to keep it from moving will feel like he or she is using as much force as is necessary to hold a 6-kg mass from dropping.

Similarly, the Nusselt number is determined using the laminar flow relations for a flat plate,

$$\text{Nu} = \frac{hL}{k} = 0.664 \text{ Re}_L^{0.5} \text{ Pr}^{1/3} = 0.664 \times (4.024 \times 10^4)^{0.5} \times 2962^{1/3} = 1913$$

Then,

$$h = \frac{k}{L} \text{ Nu} = \frac{0.1444 \text{ W/m}\cdot\text{K}}{5 \text{ m}} (1913) = 55.25 \text{ W/m}^2\cdot\text{K}$$

and

$$\dot{Q} = hA_s(T_\infty - T_s) = (55.25 \text{ W/m}^2\cdot\text{K})(5 \times 1 \text{ m}^2)(60 - 20)^\circ\text{C} = 11,050 \text{ W}$$

**Discussion** Note that heat transfer is always from the higher-temperature medium to the lower-temperature one. In this case, it is from the oil to the plate. The heat transfer rate is per m width of the plate. The heat transfer for the entire plate can be obtained by multiplying the value obtained by the actual width of the plate.

**FIGURE 7-14**

Schematic for Example 7-2.

### PFD EXAMPLE 7-2

### Prevention of Fire Hazard in the Event of Oil Leakage

Heat dissipated from an engine in operation can cause hot spots on its surface. If the outer surface of an engine is situated in a place where oil leakage is possible, then when leaked oil comes in contact with hot spots above the oil's autoignition temperature, it can ignite spontaneously. Consider an engine cover that is made of a stainless steel plate with a thickness of 1 cm and a thermal conductivity of 14 W/m·K. The stainless steel plate is covered with a 5-mm-thick insulation layer ( $k = 0.5 \text{ W/m}\cdot\text{K}$ ). The inner surface of the engine cover is exposed to hot air at 350°C with a convection heat transfer coefficient of 7 W/m²·K (Fig. 7-14). The 2-m-long engine outer surface is cooled by air blowing in parallel over it at 7 m/s, in an environment where the ambient air is at 60°C. To prevent fire hazard in the event of oil leak on the engine cover, the engine cover surface should be kept below 180°C. It has been determined that the 5-mm-thick insulation layer is not sufficient to keep the engine cover surface below 180°C. To solve this problem, one of the plant supervisors suggested adjusting the blower capacity to provide an increase in the cooling air velocity by 10%. Determine if this is a viable method for keeping the engine cover surface below 180°C. Evaluate the air properties at 120°C.

**SOLUTION** In this example, the concepts of Prevention through Design (PtD) are applied in conjunction with external forced convection and thermal resistance analysis. An engine cover with a layer of insulation is subjected to convection heat transfer on the inner and outer surfaces. To prevent fire hazard by keeping the engine outer surface temperature below 180°C, it is suggested to increase the cooling air velocity by 10%. The effectiveness of this method is to be evaluated.

**Assumptions** 1 The thermal properties of the plate and insulation are constant. 2 One-dimensional heat conduction through the plate. 3 Uniform plate surface temperature. 4 Thermal contact resistance at interface is negligible. 5 Radiation effects are negligible. 6 Local atmospheric pressure is 1 atm. 7 The critical Reynolds number is  $Re_{cr} = 5 \times 10^5$ .

**Properties** The thermal conductivities of the stainless steel and the insulation are given to be  $k_{ss} = 14 \text{ W/m}\cdot\text{K}$  and  $k_{ins} = 0.5 \text{ W/m}\cdot\text{K}$ , respectively. The properties of air are evaluated at  $T_f = 120^\circ\text{C}$ :  $k = 0.03235 \text{ W/m}\cdot\text{K}$ ,  $\nu = 2.522 \times 10^{-5} \text{ m}^2/\text{s}$ , and  $Pr = 0.7073$  (from Table A-15).

**Analysis** With increasing the cooling air velocity by 10% (7.7 m/s), the Reynolds number for the 2-m-long plate is

$$Re_L = \frac{VL}{\nu} = \frac{(7.7 \text{ m/s})(2 \text{ m})}{2.522 \times 10^{-5} \text{ m}^2/\text{s}} = 610,626 > 5 \times 10^5$$

With the Reynolds number between  $5 \times 10^5 < Re_L < 10^7$ , the proper equation is the combined laminar and turbulent relation for the Nusselt number:

$$\begin{aligned} Nu &= \frac{hL}{k} = (0.037Re_L^{0.8} - 871)Pr^{1/3} \\ &= [0.037(610,626)^{0.8} - 871](0.7073)^{1/3} \\ &= 625.77 \end{aligned}$$

The convection heat transfer coefficient on the engine outer surface is

$$h = Nu \frac{k}{L} = 625.77 \left( \frac{0.03235 \text{ W/m}\cdot\text{K}}{2 \text{ m}} \right) = 10.122 \text{ W/m}^2\cdot\text{K}$$

From Chapter 3, the thermal resistances of different layers are

$$R_{\text{conv},i} = \frac{1}{h_i A} \text{ (inside surface convection resistance)},$$

$$R_{ss} = \frac{L_{ss}}{k_{ss}A} \text{ (stainless steel layer resistance)},$$

$$R_{ins} = \frac{L_{ins}}{k_{ins}A} \text{ (insulation layer resistance)},$$

$$R_{\text{conv},o} = \frac{1}{h_o A} \text{ (outside surface convection resistance)}$$

Then,

$$\begin{aligned} AR_{\text{total}} &= A(R_{\text{conv},i} + R_{ss} + R_{ins} + R_{\text{conv},o}) = \frac{1}{h_i} + \frac{L_{ss}}{k_{ss}} + \frac{L_{ins}}{k_{ins}} + \frac{1}{h_o} \\ &= \frac{1}{7 \text{ W/m}^2\cdot\text{K}} + \frac{0.01 \text{ m}}{14 \text{ W/m}\cdot\text{K}} + \frac{0.005 \text{ m}}{0.5 \text{ W/m}\cdot\text{K}} + \frac{1}{10.122 \text{ W/m}^2\cdot\text{K}} \\ &= 0.25237 \text{ m}^2\cdot\text{K/W} \end{aligned}$$

and

$$AR_{\text{conv},o} = \frac{1}{h_o} = \frac{1}{10.122 \text{ W/m}^2\cdot\text{K}} = 0.09879 \text{ m}^2\cdot\text{K/W}$$

The heat flux through the layers is

$$\dot{q} = \frac{\dot{Q}}{A} = \frac{T_{\infty,i} - T_{\infty,o}}{AR_{\text{total}}} = \frac{T_{s,o} - T_{\infty,o}}{AR_{\text{conv},o}} \rightarrow T_{s,o} = \frac{R_{\text{conv},o}}{R_{\text{total}}}(T_{\infty,i} - T_{\infty,o}) + T_{\infty,o}$$

The outer surface temperature is

$$T_{s,o} = \frac{0.09879 \text{ m}^2\cdot\text{K/W}}{0.25237 \text{ m}^2\cdot\text{K/W}}(350 - 60)^\circ\text{C} + 60^\circ\text{C} = 173.5^\circ\text{C}$$

Yes, the suggested method is a viable method.

**Discussion** Increasing the cooling air velocity from 7 m/s to 7.7 m/s (by only 10%), kept the engine outer surface temperature below the fire hazard limit of 180°C. Another method that could be explored would be to increase the insulation thickness.

FIGURE 7–15

Schematic for Example 7–3.

### EXAMPLE 7–3 Cooling of Plastic Sheets by Forced Air

The forming section of a plastics plant puts out a continuous sheet of plastic that is 4 ft wide and 0.04 in thick at a velocity of 30 ft/min. The temperature of the plastic sheet is 200°F when it is exposed to the surrounding air, and a 2-ft-long section of the plastic sheet is subjected to air flow at 80°F at a velocity of 10 ft/s on both sides along its surfaces normal to the direction of motion of the sheet, as shown in Fig. 7–15. Determine (a) the rate of heat transfer from the plastic sheet to air by forced convection and radiation and (b) the temperature of the plastic sheet at the end of the cooling section. Take the density, specific heat, and emissivity of the plastic sheet to be  $\rho = 75 \text{ lbm/ft}^3$ ,  $c_p = 0.4 \text{ Btu/lbm}\cdot^\circ\text{F}$ , and  $\varepsilon = 0.9$ .

**SOLUTION** Plastic sheets are cooled as they leave the forming section of a plastics plant. The rate of heat loss from the plastic sheet by convection and radiation and the exit temperature of the plastic sheet are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The critical Reynolds number is  $Re_{cr} = 5 \times 10^5$ . 3 Air is an ideal gas. 4 The local atmospheric pressure is 1 atm. 5 The surrounding surfaces are at the temperature of the room air.

**Properties** The properties of the plastic sheet are given in the problem statement. The properties of air at the film temperature of  $T_f = (T_s + T_\infty)/2 = (200 + 80)/2 = 140^\circ\text{F}$  and 1 atm pressure are (Table A–15E)

$$k = 0.01623 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F} \quad \Pr = 0.7202 \\ \nu = 0.204 \times 10^{-3} \text{ ft}^2/\text{s}$$

**Analysis** (a) We expect the temperature of the plastic sheet to drop somewhat as it flows through the 2-ft-long cooling section, but at this point we do not know the magnitude of that drop. Therefore, we assume the plastic sheet to be isothermal at 200°F to get started. We will repeat the calculations if necessary to account for the temperature drop of the plastic sheet.

Noting that  $L = 4$  ft, the Reynolds number at the end of the air flow across the plastic sheet is

$$\text{Re}_L = \frac{VL}{\nu} = \frac{(10 \text{ ft/s})(4 \text{ ft})}{0.204 \times 10^{-3} \text{ ft}^2/\text{s}} = 1.961 \times 10^5$$

which is less than the critical Reynolds number. Thus, we have *laminar flow* over the entire sheet, and the Nusselt number is determined from the laminar flow relations for a flat plate to be

$$\text{Nu} = \frac{hL}{k} = 0.664 \text{ Re}_L^{0.5} \text{ Pr}^{1/3} = 0.664 \times (1.961 \times 10^5)^{0.5} \times (0.7202)^{1/3} = 263.6$$

Then,

$$h = \frac{k}{L} \text{ Nu} = \frac{0.01623 \text{ Btu/h}\cdot\text{ft}\cdot{}^{\circ}\text{F}}{4 \text{ ft}} (263.6) = 1.07 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^{\circ}\text{F}$$

$$A_s = (2 \text{ ft})(4 \text{ ft})(2 \text{ sides}) = 16 \text{ ft}^2$$

and

$$\begin{aligned} \dot{Q}_{\text{conv}} &= hA_s(T_s - T_{\infty}) \\ &= (1.07 \text{ Btu/h}\cdot\text{ft}^2\cdot{}^{\circ}\text{F})(16 \text{ ft}^2)(200 - 80){}^{\circ}\text{F} \\ &= 2054 \text{ Btu/h} \\ \dot{Q}_{\text{rad}} &= \varepsilon\sigma A_s(T_s^4 - T_{\text{surr}}^4) \\ &= (0.9)(0.1714 \times 10^{-8} \text{ Btu/h}\cdot\text{ft}^2\cdot\text{R}^4)(16 \text{ ft}^2)[(660 \text{ R})^4 - (540 \text{ R})^4] \\ &= 2585 \text{ Btu/h} \end{aligned}$$

Therefore, the rate of cooling of the plastic sheet by combined convection and radiation is

$$\dot{Q}_{\text{total}} = \dot{Q}_{\text{conv}} + \dot{Q}_{\text{rad}} = 2054 + 2585 = \mathbf{4639 \text{ Btu/h}}$$

(b) To find the temperature of the plastic sheet at the end of the cooling section, we need to know the mass of the plastic rolling out per unit time (or the mass flow rate), which is determined from

$$\dot{m} = \rho A_c V_{\text{plastic}} = (75 \text{ lbm/ft}^3) \left( \frac{4 \times 0.04}{12} \text{ ft}^2 \right) \left( \frac{30}{60} \text{ ft/s} \right) = 0.5 \text{ lbm/s}$$

Then, an energy balance on the cooled section of the plastic sheet yields

$$\dot{Q} = \dot{m}c_p(T_2 - T_1) \rightarrow T_2 = T_1 + \frac{\dot{Q}}{\dot{m}c_p}$$

Noting that  $\dot{Q}$  is a negative quantity (heat loss) for the plastic sheet and substituting, the temperature of the plastic sheet as it leaves the cooling section is determined to be

$$T_2 = 200{^{\circ}\text{F}} + \frac{-4639 \text{ Btu/h}}{(0.5 \text{ lbm/s})(0.4 \text{ Btu/lbm}\cdot{}^{\circ}\text{F})} \left( \frac{1 \text{ h}}{3600 \text{ s}} \right) = \mathbf{193.6{^{\circ}\text{F}}}$$

**Discussion** The average temperature of the plastic sheet drops by about  $6.4{^{\circ}\text{F}}$  as it passes through the cooling section. The calculations now can be repeated by taking the average temperature of the plastic sheet to be  $196.8{^{\circ}\text{F}}$  instead of  $200{^{\circ}\text{F}}$  for better accuracy, but the change in the results will be insignificant because of the small change in temperature.

## 7–3 ■ FLOW ACROSS CYLINDERS AND SPHERES

Flow across cylinders and spheres is frequently encountered in practice. For example, the tubes in a shell-and-tube heat exchanger involve both *internal flow* through the tubes and *external flow* over the tubes, and both flows must be considered in the analysis of the heat exchanger. Also, many sports such as soccer, tennis, and golf involve flow over spherical balls.

The characteristic length for a circular cylinder or sphere is taken to be the *external diameter*  $D$ . Thus, the Reynolds number is defined as  $\text{Re} = \text{Re}_D = VD/\nu$  where  $V$  is the uniform velocity of the fluid as it approaches the cylinder or sphere. The critical Reynolds number for flow across a circular cylinder or sphere is about  $\text{Re}_{\text{cr}} \approx 2 \times 10^5$ . That is, the boundary layer remains laminar for about  $\text{Re} \leq 2 \times 10^5$  and becomes turbulent for  $\text{Re} \geq 2 \times 10^5$ .

Cross-flow over a cylinder exhibits complex flow patterns, as shown in Fig. 7–16. The fluid approaching the cylinder branches out and encircles the cylinder, forming a boundary layer that wraps around the cylinder. The fluid particles on the midplane strike the cylinder at the stagnation point, bringing the fluid to a complete stop and thus raising the pressure at that point. The pressure decreases in the flow direction while the fluid velocity increases.

At very low upstream velocities ( $\text{Re} \leq 1$ ), the fluid completely wraps around the cylinder and the two arms of the fluid meet on the rear side of the cylinder in an orderly manner. Thus, the fluid follows the curvature of the cylinder. At higher velocities, the fluid still hugs the cylinder on the frontal side, but it is too fast to remain attached to the surface as it approaches the top (or bottom) of the cylinder. As a result, the boundary layer detaches from the surface, forming a separation region behind the cylinder. Flow in the wake region is characterized by periodic vortex formation and pressures much lower than the stagnation point pressure.

The nature of the flow across a cylinder or sphere strongly affects the total drag coefficient  $C_D$ . Both the *friction drag* and the *pressure drag* can be significant. The high pressure in the vicinity of the stagnation point and the low pressure on the opposite side in the wake produce a net force on the body in the direction of flow. The drag force is primarily due to friction drag at low Reynolds numbers ( $\text{Re} < 10$ ) and to pressure drag at high Reynolds numbers ( $\text{Re} > 5000$ ). Both effects are significant at intermediate Reynolds numbers.

From dimensional analysis it can be shown that the average drag coefficients  $C_D$  for a smooth single circular cylinder and a sphere is a function of Reynolds number,  $C_D = f(\text{Re}_D)$ , as shown in Fig. 7–17. The curves exhibit different behaviors in different ranges of Reynolds numbers:

**FIGURE 7–16**

Laminar boundary layer separation with a turbulent wake; flow over a circular cylinder at  $\text{Re} = 2000$ .

*Courtesy ONERA, photograph by Werlé.*

**FIGURE 7-17**

Average drag coefficient for cross-flow over a smooth circular cylinder and a smooth sphere.

*From H. Schlichting, Boundary Layer Theory 7e. Copyright ©1979 The McGraw-Hill Companies, Inc. Used by permission.*

- For  $Re \leq 1$ , we have creeping flow, and the drag coefficient decreases with increasing Reynolds number. For a sphere, it is  $C_D = 24/Re$ . There is no flow separation in this regime.
- At about  $Re = 10$ , separation starts occurring on the rear of the body with vortex shedding starting at about  $Re \approx 90$ . The region of separation increases with increasing Reynolds number up to about  $Re = 10^3$ . At this point, the drag is mostly (about 95 percent) due to pressure drag. The drag coefficient continues to decrease with increasing Reynolds number in this range of  $10 < Re < 10^3$ . (A decrease in the drag coefficient does not necessarily indicate a decrease in drag. The drag force is proportional to the square of the velocity, and the increase in velocity at higher Reynolds numbers usually more than offsets the decrease in the drag coefficient.)
- In the moderate range of  $10^3 < Re < 10^5$ , the drag coefficient remains relatively constant. This behavior is characteristic of blunt bodies. The flow in the boundary layer is laminar in this range, but the flow in the separated region past the cylinder or sphere is highly turbulent with a wide turbulent wake.
- There is a sudden drop in the drag coefficient somewhere in the range of  $10^5 < Re < 10^6$  (usually, at about  $2 \times 10^5$ ). This large reduction in  $C_D$  is due to the flow in the boundary layer becoming *turbulent*, which moves the separation point further on the rear of the body, reducing the size of the wake and thus the magnitude of the pressure drag. This is in contrast to streamlined bodies, which experience an increase in the drag coefficient (mostly due to friction drag) when the boundary layer becomes turbulent.

Flow separation occurs at about  $\theta \approx 80^\circ$  (measured from the front stagnation point of a cylinder) when the boundary layer is *laminar* and at about  $\theta \approx 140^\circ$  when it is *turbulent* (Fig. 7-18). The delay of separation in turbulent flow is caused by the rapid fluctuations of the fluid in the transverse direction, which enables the turbulent boundary layer to travel farther along the surface before separation occurs, resulting in a narrower wake and a smaller pressure drag. Keep in mind that turbulent flow has a fuller velocity profile as compared to the laminar case, and thus it requires a stronger adverse pressure

(a)

(b)

**FIGURE 7-18**

Flow visualization of flow over (a) a smooth sphere at  $Re = 15,000$ , and (b) a sphere at  $Re = 30,000$  with a trip wire. The delay of boundary layer separation is clearly seen by comparing the two photographs.

*Courtesy ONERA, photograph by Werlé.*

gradient to overcome the additional momentum close to the wall. In the range of Reynolds numbers where the flow changes from laminar to turbulent, even the drag force  $F_D$  decreases as the velocity (and thus the Reynolds number) increases. This results in a sudden decrease in drag of a flying body (sometimes called the *drag crisis*) and instabilities in flight.

## Effect of Surface Roughness

We mentioned earlier that *surface roughness*, in general, increases the drag coefficient in turbulent flow. This is especially the case for streamlined bodies. For blunt bodies such as a circular cylinder or sphere, however, an increase in the surface roughness may actually *decrease* the drag coefficient, as shown in Fig. 7–19 for a sphere. This is done by tripping the boundary layer into turbulence at a lower Reynolds number, and thus causing the fluid to close in behind the body, narrowing the wake and reducing pressure drag considerably. This results in a much smaller drag coefficient and thus drag force for a rough-surfaced cylinder or sphere in a certain range of Reynolds number compared to a smooth one of identical size at the same velocity. At  $Re = 2 \times 10^5$ , for example,  $C_D \approx 0.1$  for a rough sphere with  $\epsilon/D = 0.0015$ , whereas  $C_D \approx 0.5$  for a smooth one. Therefore, the drag coefficient in this case is reduced by a factor of 5 by simply roughening the surface. Note, however, that at  $Re = 10^6$ ,  $C_D \approx 0.4$  for a very rough sphere while  $C_D \approx 0.1$  for the smooth one. Obviously, roughening the sphere in this case will increase the drag by a factor of 4 (Fig. 7–20).

The preceding discussion shows that roughening the surface can be used to great advantage in reducing drag, but it can also backfire on us if we are not careful—specifically, if we do not operate in the right range of the Reynolds number. With this consideration, golf balls are intentionally roughened to induce *turbulence* at a lower Reynolds number to take advantage of the sharp *drop* in the drag coefficient at the onset of turbulence in the boundary layer (the typical velocity range of golf balls is 15 to 150 m/s, and the Reynolds number is less than  $4 \times 10^5$ ). The critical Reynolds number of dimpled golf balls is about  $4 \times 10^4$ . The occurrence of turbulent flow at this Reynolds number reduces the drag

**FIGURE 7–19**

The effect of surface roughness on the drag coefficient of a sphere.

From Blevins (1984).

coefficient of a golf ball by about half, as shown in Fig. 7–19. For a given hit, this means a longer distance for the ball. Experienced golfers also give the ball a spin during the hit, which helps the rough ball develop a lift and thus travel higher and farther. A similar argument can be given for a tennis ball. For a table tennis ball, however, the distances are very short, and the balls never reach the speeds in the turbulent range. Therefore, the surfaces of table tennis balls are made smooth.

Once the drag coefficient is available, the drag force acting on a body in cross-flow can be determined from Eq. 7–1 where  $A$  is the *frontal area* ( $A = LD$  for a cylinder of length  $L$  and  $A = \pi D^2/4$  for a sphere). It should be kept in mind that free-stream turbulence and disturbances by other bodies in the flow (such as flow over tube bundles) may affect the drag coefficients significantly.

### EXAMPLE 7–4 Drag Force Acting on a Pipe in a River

A 2.2-cm-outer-diameter pipe is to span across a river at a 30-m-wide section while being completely immersed in water (Fig. 7–21). The average flow velocity of water is 4 m/s and the water temperature is 15°C. Determine the drag force exerted on the pipe by the river.

**SOLUTION** A pipe is submerged in a river. The drag force that acts on the pipe is to be determined.

**Assumptions** 1 The outer surface of the pipe is smooth so that Fig. 7–17 can be used to determine the drag coefficient. 2 Water flow in the river is steady. 3 The direction of water flow is normal to the pipe. 4 Turbulence in river flow is not considered.

**Properties** The density and dynamic viscosity of water at 15°C are  $\rho = 999.1 \text{ kg/m}^3$  and  $\mu = 1.138 \times 10^{-3} \text{ kg/m}\cdot\text{s}$  (Table A–9).

**Analysis** Noting that  $D = 0.022 \text{ m}$ , the Reynolds number is

$$\text{Re} = \frac{VD}{\nu} = \frac{\rho VD}{\mu} = \frac{(999.1 \text{ kg/m}^3)(4 \text{ m/s})(0.022 \text{ m})}{1.138 \times 10^{-3} \text{ kg/m}\cdot\text{s}} = 7.73 \times 10^4$$

The drag coefficient corresponding to this value is, from Fig. 7–17,  $C_D = 1.0$ . Also, the frontal area for flow past a cylinder is  $A = LD$ . Then the drag force acting on the pipe becomes

$$\begin{aligned} F_D &= C_D A \frac{\rho V^2}{2} = 1.0(30 \times 0.022 \text{ m}^2) \frac{(999.1 \text{ kg/m}^3)(4 \text{ m/s})^2}{2} \left( \frac{1 \text{ N}}{1 \text{ kg}\cdot\text{m/s}^2} \right) \\ &= 5275 \text{ N} \approx \mathbf{5.30 \text{ kN}} \end{aligned}$$

**Discussion** Note that this force is equivalent to the weight of a mass over 500 kg. Therefore, the drag force the river exerts on the pipe is equivalent to hanging a total of over 500 kg in mass on the pipe supported at its ends 30 m apart. The necessary precautions should be taken if the pipe cannot support this force. If the river were to flow at a faster speed or if turbulent fluctuations in the river were more significant, the drag force would be even larger. *Unsteady* forces on the pipe might then be significant.

FIGURE 7–20

Surface roughness may increase or decrease the drag coefficient of a spherical object, depending on the value of the Reynolds number.

**FIGURE 7-22**

Variation of the local heat transfer coefficient along the circumference of a circular cylinder in cross flow of air.  
From Giedt, 1949.

## Heat Transfer Coefficient

Flows across cylinders and spheres, in general, involve *flow separation*, which is difficult to handle analytically. Therefore, such flows must be studied experimentally or numerically. Indeed, flow across cylinders and spheres has been studied experimentally by numerous investigators, and several empirical correlations have been developed for the heat transfer coefficient.

The complicated flow pattern across a cylinder greatly influences heat transfer. The variation of the local Nusselt number  $Nu_\theta$  around the periphery of a cylinder subjected to cross flow of air is given in Fig. 7-22. Note that, for all cases, the value of  $Nu_\theta$  starts out relatively high at the stagnation point ( $\theta = 0^\circ$ ) but decreases with increasing  $\theta$  as a result of the thickening of the laminar boundary layer. On the two curves at the bottom corresponding to  $Re = 70,800$  and  $101,300$ ,  $Nu_\theta$  reaches a minimum at  $\theta \approx 80^\circ$ , which is the separation point in laminar flow. Then  $Nu_\theta$  increases with increasing  $\theta$  as a result of the intense mixing in the separated flow region (the wake). The curves at the top corresponding to  $Re = 140,000$  to  $219,000$  differ from the first two curves in that they have *two* minima for  $Nu_\theta$ . The sharp increase in  $Nu_\theta$  at about  $\theta \approx 90^\circ$  is due to the transition from laminar to turbulent flow. The later decrease in  $Nu_\theta$  is again due to the thickening of the boundary layer.  $Nu_\theta$  reaches its second minimum at about  $\theta \approx 140^\circ$ , which is the flow separation point in turbulent flow, and increases with  $\theta$  as a result of the intense mixing in the turbulent wake region.

The discussions above on the local heat transfer coefficients are insightful; however, they are of limited value in heat transfer calculations since the calculation of heat transfer requires the *average* heat transfer coefficient over the entire surface. Of the several such relations available in the literature for the average Nusselt number for cross flow over a cylinder, we present the one proposed by Churchill and Bernstein (1977):

$$Nu_{cyl} = \frac{hD}{k} = 0.3 + \frac{0.62 Re^{1/2} Pr^{1/3}}{[1 + (0.4/Pr)^{2/3}]^{1/4}} \left[ 1 + \left( \frac{Re}{282,000} \right)^{5/8} \right]^{4/5} \quad (7-35)$$

This relation is quite comprehensive in that it correlates available data well for  $RePr > 0.2$ . The fluid properties are evaluated at the *film temperature*  $T_f = \frac{1}{2}(T_\infty + T_s)$ , which is the average of the free-stream and surface temperatures.

For flow over a *sphere*, Whitaker (1972) recommends the following comprehensive correlation:

$$Nu_{sph} = \frac{hD}{k} = 2 + [0.4 Re^{1/2} + 0.06 Re^{2/3}] Pr^{0.4} \left( \frac{\mu_\infty}{\mu_s} \right)^{1/4} \quad (7-36)$$

which is valid for  $3.5 \leq Re \leq 8 \times 10^4$ ,  $0.7 \leq Pr \leq 380$  and  $1.0 \leq (\mu_\infty/\mu_s) \leq 3.2$ . The fluid properties in this case are evaluated at the free-stream temperature  $T_\infty$ , except for  $\mu_s$ , which is evaluated at the surface temperature  $T_s$ . Although the two relations above are considered to be quite accurate, the results obtained from them can be off by as much as 30 percent.

The average Nusselt number for flow across cylinders can be expressed compactly as

$$Nu_{cyl} = \frac{hD}{k} = C Re^m Pr^n \quad (7-37)$$

where  $n = \frac{1}{3}$  and the experimentally determined constants  $C$  and  $m$  are given in Table 7-1 for circular as well as various noncircular cylinders.

The characteristic length  $D$  for use in the calculation of the Reynolds and the Nusselt numbers for different geometries is as indicated on the figure. All fluid properties are evaluated at the film temperature. Note that the values presented in Table 7–1 for non-circular geometries have been updated based on the recommendations of Sparrow et al. (2004).

**TABLE 7–1**

Empirical correlations for the average Nusselt number for forced convection over circular and noncircular cylinders in cross flow (from Zukauskas, 1972, Jakob 1949, and Sparrow et al., 2004)

| Cross-section of the cylinder   | Fluid         | Range of Re   | Nusselt number  |
|---|---------------|---|---|
| Circle<br>                 | Gas or liquid | 0.4–4<br>4–40<br>40–4000<br>4000–40,000<br>40,000–400,000 | $\text{Nu} = 0.989\text{Re}^{0.330}\text{Pr}^{1/3}$<br>$\text{Nu} = 0.911\text{Re}^{0.385}\text{Pr}^{1/3}$<br>$\text{Nu} = 0.683\text{Re}^{0.466}\text{Pr}^{1/3}$<br>$\text{Nu} = 0.193\text{Re}^{0.618}\text{Pr}^{1/3}$<br>$\text{Nu} = 0.027\text{Re}^{0.805}\text{Pr}^{1/3}$ |
| Square<br>                 | Gas           | 3900–79,000   | $\text{Nu} = 0.094\text{Re}^{0.675}\text{Pr}^{1/3}$   |
| Square (tilted 45°)<br>   | Gas           | 5600–111,000  | $\text{Nu} = 0.258\text{Re}^{0.588}\text{Pr}^{1/3}$   |
| Hexagon<br>              | Gas           | 4500–90,700   | $\text{Nu} = 0.148\text{Re}^{0.638}\text{Pr}^{1/3}$   |
| Hexagon (tilted 45°)<br> | Gas           | 5200–20,400<br>20,400–105,000                             | $\text{Nu} = 0.162\text{Re}^{0.638}\text{Pr}^{1/3}$<br>$\text{Nu} = 0.039\text{Re}^{0.782}\text{Pr}^{1/3}$  |
| Vertical plate<br>       | Gas           | 6300–23,600   | $\text{Nu} = 0.257\text{Re}^{0.731}\text{Pr}^{1/3}$   |
| Ellipse<br>              | Gas           | 1400–8200   | $\text{Nu} = 0.197\text{Re}^{0.612}\text{Pr}^{1/3}$   |

The relations for cylinders above are for *single* cylinders or cylinders oriented such that the flow over them is not affected by the presence of others. Also, they are applicable to *smooth* surfaces. *Surface roughness* and the *free-stream turbulence* may affect the drag and heat transfer coefficients significantly. Eq. 7-37 provides a simpler alternative to Eq. 7-35 for flow over cylinders. However, Eq. 7-35 is more accurate, and thus should be preferred in calculations whenever possible.

**FIGURE 7-23**

Schematic for Example 7-5.

### EXAMPLE 7-5 Heat Loss from a Steam Pipe in Windy Air

A long 10-cm-diameter steam pipe whose external surface temperature is  $110^\circ\text{C}$  passes through some open area that is not protected against the winds (Fig. 7-23). Determine the rate of heat loss from the pipe per unit of its length when the air is at 1 atm pressure and  $10^\circ\text{C}$  and the wind is blowing across the pipe at a velocity of 8 m/s.

**SOLUTION** A steam pipe is exposed to windy air. The rate of heat loss from the steam is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Radiation effects are negligible. 3 Air is an ideal gas.

**Properties** The properties of air at the average film temperature of  $T_f = (T_s + T_\infty)/2 = (110 + 10)/2 = 60^\circ\text{C}$  and 1 atm pressure are (Table A-15)

$$k = 0.02808 \text{ W/m}\cdot\text{K} \quad \text{Pr} = 0.7202 \quad \nu = 1.896 \times 10^{-5} \text{ m}^2/\text{s}$$

**Analysis** The Reynolds number is

$$\text{Re} = \frac{VD}{\nu} = \frac{(8 \text{ m/s})(0.1 \text{ m})}{1.896 \times 10^{-5} \text{ m}^2/\text{s}} = 4.219 \times 10^4$$

The Nusselt number can be determined from

$$\begin{aligned} \text{Nu} &= \frac{hD}{k} = 0.3 + \frac{0.62 \text{ Re}^{1/2} \text{ Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}} \left[ 1 + \left( \frac{\text{Re}}{282,000} \right)^{5/8} \right]^{4/5} \\ &= 0.3 + \frac{0.62(4.219 \times 10^4)^{1/2} (0.7202)^{1/3}}{[1 + (0.4/0.7202)^{2/3}]^{1/4}} \left[ 1 + \left( \frac{4.219 \times 10^4}{282,000} \right)^{5/8} \right]^{4/5} \\ &= 124 \end{aligned}$$

and

$$h = \frac{k}{D} \text{ Nu} = \frac{0.02808 \text{ W/m}\cdot\text{K}}{0.1 \text{ m}} (124) = 34.8 \text{ W/m}^2\cdot\text{K}$$

Then, the rate of heat transfer from the pipe per unit of its length becomes

$$A_s = pL = \pi DL = \pi(0.1 \text{ m})(1 \text{ m}) = 0.314 \text{ m}^2$$

$$\dot{Q} = hA_s(T_s - T_\infty) = (34.8 \text{ W/m}^2\cdot\text{K})(0.314 \text{ m}^2)(110 - 10)^\circ\text{C} = 1093 \text{ W}$$

The rate of heat loss from the entire pipe can be obtained by multiplying the value above by the length of the pipe in m.

**Discussion** The simpler Nusselt number relation in Table 7-1 in this case would give  $\text{Nu} = 128$ , which is 3 percent higher than the value obtained above using Eq. 7-35.

**EXAMPLE 7–6 Cooling of a Steel Ball by Forced Air**

A 25-cm-diameter stainless steel ball ( $\rho = 8055 \text{ kg/m}^3$ ,  $c_p = 480 \text{ J/kg}\cdot\text{K}$ ) is removed from the oven at a uniform temperature of  $300^\circ\text{C}$  (Fig. 7–24). The ball is then subjected to the flow of air at 1 atm pressure and  $25^\circ\text{C}$  with a velocity of 3 m/s. The surface temperature of the ball eventually drops to  $200^\circ\text{C}$ . Determine the average convection heat transfer coefficient during this cooling process and estimate how long the process will take.

**SOLUTION** A hot stainless steel ball is cooled by forced air. The average convection heat transfer coefficient and the cooling time are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Radiation effects are negligible. 3 Air is an ideal gas. 4 The outer surface temperature of the ball is uniform at all times. 5 The surface temperature of the ball during cooling is changing. Therefore, the convection heat transfer coefficient between the ball and the air will also change. To avoid this complexity, we take the surface temperature of the ball to be constant at the average temperature of  $(300 + 200)/2 = 250^\circ\text{C}$  in the evaluation of the heat transfer coefficient and use the value obtained for the entire cooling process.

**Properties** The dynamic viscosity of air at the average surface temperature is  $\mu_s = \mu @ 250^\circ\text{C} = 2.76 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ . The properties of air at the free-stream temperature of  $25^\circ\text{C}$  and 1 atm are (Table A–15)

$$k = 0.02551 \text{ W/m}\cdot\text{K}$$

$$\nu = 1.562 \times 10^{-5} \text{ m}^2/\text{s}$$

$$\mu = 1.849 \times 10^{-5} \text{ kg/m}\cdot\text{s}$$

$$\text{Pr} = 0.7296$$

**Analysis** The Reynolds number is determined from

$$\text{Re} = \frac{VD}{\nu} = \frac{(3 \text{ m/s})(0.25 \text{ m})}{1.562 \times 10^{-5} \text{ m}^2/\text{s}} = 4.802 \times 10^4$$

The Nusselt number is

$$\begin{aligned} \text{Nu} &= \frac{hD}{k} = 2 + [0.4 \text{ Re}^{1/2} + 0.06 \text{ Re}^{2/3}] \text{ Pr}^{0.4} \left( \frac{\mu_\infty}{\mu_s} \right)^{1/4} \\ &= 2 + [0.4(4.802 \times 10^4)^{1/2} + 0.06(4.802 \times 10^4)^{2/3}] (0.7296)^{0.4} \\ &\quad \times \left( \frac{1.849 \times 10^{-5}}{2.76 \times 10^{-5}} \right)^{1/4} \\ &= 135 \end{aligned}$$

Then the average convection heat transfer coefficient becomes

$$h = \frac{k}{D} \text{ Nu} = \frac{0.02551 \text{ W/m}\cdot\text{K}}{0.25 \text{ m}} (135) = 13.8 \text{ W/m}^2\cdot\text{K}$$

In order to estimate the time of cooling of the ball from  $300^\circ\text{C}$  to  $200^\circ\text{C}$ , we determine the *average* rate of heat transfer from Newton's law of cooling by using the *average* surface temperature. That is,

$$A_s = \pi D^2 = \pi(0.25 \text{ m})^2 = 0.1963 \text{ m}^2$$

$$\dot{Q}_{\text{avg}} = hA_s(T_{s,\text{avg}} - T_\infty) = (13.8 \text{ W/m}^2\cdot\text{K})(0.1963 \text{ m}^2)(250 - 25)^\circ\text{C} = 610 \text{ W}$$

**FIGURE 7–24**

Schematic for Example 7–6.

Next we determine the *total* heat transferred from the ball, which is simply the change in the energy of the ball as it cools from 300°C to 200°C:

$$m = \rho V = \rho \frac{1}{6}\pi D^3 = (8055 \text{ kg/m}^3) \frac{1}{6}\pi(0.25 \text{ m})^3 = 65.9 \text{ kg}$$

$$Q_{\text{total}} = mc_p(T_2 - T_1) = (65.9 \text{ kg})(480 \text{ J/kg}\cdot\text{K})(300 - 200)^\circ\text{C} = 3,163,000 \text{ J}$$

In this calculation, we assumed that the entire ball is at 200°C, which is not necessarily true. The inner region of the ball will probably be at a higher temperature than its surface. With this assumption, the time of cooling is determined to be

$$\Delta t \approx \frac{Q}{\dot{Q}_{\text{avg}}} = \frac{3,163,000 \text{ J}}{610 \text{ J/s}} = 5185 \text{ s} = \mathbf{1 \text{ h } 26 \text{ min}}$$

**Discussion** The time of cooling could also be determined more accurately using the transient temperature charts or relations introduced in Chapter 4. But the simplifying assumptions we made above can be justified if all we need is a ballpark value. It will be naive to expect the time of cooling to be exactly 1 h 26 min, but, using our engineering judgment, it is realistic to expect the time of cooling to be somewhere between one and two hours.

**FIGURE 7-25**

Flow patterns for in-line and staggered tube banks.

## 7-4 ■ FLOW ACROSS TUBE BANKS

Cross-flow over tube banks is commonly encountered in practice in heat transfer equipment such as the condensers and evaporators of power plants, refrigerators, and air conditioners. In such equipment, one fluid moves through the tubes while the other moves over the tubes in a perpendicular direction.

In a heat exchanger that involves a tube bank, the tubes are usually placed in a *shell* (and thus the *name shell-and-tube heat exchanger*), especially when the fluid is a liquid, and the fluid flows through the space between the tubes and the shell. There are numerous types of shell-and-tube heat exchangers, some of which are considered in Chap. 11. In this section we consider the general aspects of flow over a tube bank, and try to develop a better and more intuitive understanding of the performance of heat exchangers involving a tube bank.

Flow *through* the tubes can be analyzed by considering flow through a single tube, and multiplying the results by the number of tubes. This is not the case for flow *over* the tubes, however, since the tubes affect the flow pattern and turbulence level downstream, and thus heat transfer to or from them, as shown in Fig. 7-25. Therefore, when analyzing heat transfer from a tube bank in cross flow, we must consider all the tubes in the bundle at once.

The tubes in a tube bank are usually arranged either *in-line* or *staggered* in the direction of flow, as shown in Fig. 7-26. The outer tube diameter  $D$  is taken as the characteristic length. The arrangement of the tubes in the tube bank is characterized by the *transverse pitch*  $S_T$ , *longitudinal pitch*  $S_L$ , and the *diagonal pitch*  $S_D$  between tube centers. The diagonal pitch is determined from

$$S_D = \sqrt{S_L^2 + (S_T/2)^2} \quad (7-38)$$

As the fluid enters the tube bank, the flow area decreases from  $A_1 = S_T L$  to  $A_T = (S_T - D)L$  between the tubes, and thus flow velocity increases. In staggered arrangement, the velocity may increase further in the diagonal region if the tube rows are very close to each other. In tube banks, the flow characteristics are dominated by the maximum velocity  $V_{\max}$  that occurs within the tube bank rather than the approach velocity  $V$ . Therefore, the Reynolds number is defined on the basis of maximum velocity as

$$\text{Re}_D = \frac{\rho V_{\max} D}{\mu} = \frac{V_{\max} D}{\nu} \quad (7-39)$$

The maximum velocity is determined from the conservation of mass requirement for steady incompressible flow. For *in-line* arrangement, the maximum velocity occurs at the minimum flow area between the tubes, and the conservation of mass can be expressed as (see Fig. 7-26a)  $\rho V A_1 = \rho V_{\max} A_T$  or  $VS_T = V_{\max}(S_T - D)$ . Then the maximum velocity becomes

$$V_{\max} = \frac{S_T}{S_T - D} V \quad (7-40)$$

In *staggered* arrangement, the fluid approaching through area  $A_1$  in Fig. 7-26b passes through area  $A_T$  and then through area  $2A_D$  as it wraps around the pipe in the next row. If  $2A_D > A_T$ , maximum velocity still occurs at  $A_T$  between the tubes and thus the  $V_{\max}$  relation Eq. 7-40 can also be used for staggered tube banks. But if  $2A_D < A_T$  [or, if  $2(S_D - D) < (S_T - D)$ ], maximum velocity occurs at the diagonal cross sections, and the maximum velocity in this case becomes

$$\text{Staggered and } S_D < (S_T + D)/2: \quad V_{\max} = \frac{S_T}{2(S_D - D)} V \quad (7-41)$$

since  $\rho V A_1 = \rho V_{\max}(2A_D)$  or  $VS_T = 2V_{\max}(S_D - D)$ .

The nature of flow around a tube in the first row resembles flow over a single tube discussed in Section 7-3, especially when the tubes are not too close to each other. Therefore, each tube in a tube bank that consists of a single transverse row can be treated as a single tube in cross-flow. The nature of flow around a tube in the second and subsequent rows is very different, however, because of wakes formed and the turbulence caused by the tubes upstream. The level of turbulence, and thus the heat transfer coefficient, increases with row number because of the combined effects of upstream rows. But there is no significant change in turbulence level after the first few rows, and thus the heat transfer coefficient remains constant.

Flow through tube banks is studied experimentally since it is too complex to be treated analytically. We are primarily interested in the average heat transfer coefficient for the entire tube bank, which depends on the number of tube rows along the flow as well as the arrangement and the size of the tubes.

Several correlations, all based on experimental data, have been proposed for the average Nusselt number for cross flow over tube banks. More recently, Zukauskas (1987) has proposed correlations whose general form is

$$\text{Nu}_D = \frac{hD}{k} = C \text{Re}_D^m \text{Pr}^n (\text{Pr}/\text{Pr}_s)^{0.25} \quad (7-42)$$

**FIGURE 7-26**

Arrangement of the tubes in in-line and staggered tube banks ( $A_1$ ,  $A_T$ , and  $A_D$  are flow areas at indicated locations, and  $L$  is the length of the tubes).

where the values of the constants  $C$ ,  $m$ , and  $n$  depend on Reynolds number. Such correlations are given in Table 7–2 for tube banks with more than 16 rows ( $N_L > 16$ ),  $0.7 < \text{Pr} < 500$  and  $0 < \text{Re}_D < 2 \times 10^6$ . The uncertainty in the values of Nusselt number obtained from these relations is  $\pm 15$  percent. Note that all properties except  $\text{Pr}_s$  are to be evaluated at the arithmetic mean temperature of the fluid determined from

$$T_m = \frac{T_i + T_e}{2} \quad (7-43)$$

where  $T_i$  and  $T_e$  are the fluid temperatures at the inlet and the exit of the tube bank, respectively.

The average Nusselt number relations in Table 7–2 are for tube banks with more than 16 rows. Those relations can also be used for tube banks with  $N_L < 16$  provided that they are modified as

$$\text{Nu}_{D, N_L < 16} = F \text{Nu}_D \quad (7-44)$$

where  $F$  is a *correction factor*  $F$  whose values are given in Table 7–3. For  $\text{Re}_D > 1000$ , the correction factor is independent of Reynolds number.

Once the Nusselt number and thus the average heat transfer coefficient for the entire tube bank is known, the heat transfer rate can be determined from

**TABLE 7–2**

Nusselt number correlations for cross flow over tube banks for  $N_L > 16$  and  $0.7 < \text{Pr} < 500$  (from Zukauskas, 1987)\*

| Arrangement | Range of $\text{Re}_D$            | Correlation   |
|-------------|-----------------------------------|---|
| In-line     | 0–100                             | $\text{Nu}_D = 0.9 \text{Re}_D^{0.4} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$                                 |
|             | 100–1000                          | $\text{Nu}_D = 0.52 \text{Re}_D^{0.5} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$                                |
|             | 1000– $2 \times 10^5$             | $\text{Nu}_D = 0.27 \text{Re}_D^{0.63} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$                               |
|             | $2 \times 10^5$ – $2 \times 10^6$ | $\text{Nu}_D = 0.033 \text{Re}_D^{0.8} \text{Pr}^{0.4} (\text{Pr}/\text{Pr}_s)^{0.25}$                                |
| Staggered   | 0–500                             | $\text{Nu}_D = 1.04 \text{Re}_D^{0.4} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$                                |
|             | 500–1000                          | $\text{Nu}_D = 0.71 \text{Re}_D^{0.5} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$                                |
|             | 1000– $2 \times 10^5$             | $\text{Nu}_D = 0.35 (\text{S}_T/\text{S}_L)^{0.2} \text{Re}_D^{0.6} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$  |
|             | $2 \times 10^5$ – $2 \times 10^6$ | $\text{Nu}_D = 0.031 (\text{S}_T/\text{S}_L)^{0.2} \text{Re}_D^{0.8} \text{Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25}$ |

\*All properties except  $\text{Pr}_s$  are to be evaluated at the arithmetic mean of the inlet and outlet temperatures of the fluid ( $\text{Pr}_s$  is to be evaluated at  $T_s$ ).

**TABLE 7–3**

Correction factor  $F$  to be used in  $\text{Nu}_{D, N_L < 16} = F \text{Nu}_D$  for  $N_L > 16$  and  $\text{Re}_D > 1000$  (from Zukauskas, 1987)

| $N_L$     | 1    | 2    | 3    | 4    | 5    | 7    | 10   | 13   |
|-----------|------|------|------|------|------|------|------|------|
| In-line   | 0.70 | 0.80 | 0.86 | 0.90 | 0.93 | 0.96 | 0.98 | 0.99 |
| Staggered | 0.64 | 0.76 | 0.84 | 0.89 | 0.93 | 0.96 | 0.98 | 0.99 |

Newton's law of cooling using a suitable temperature difference  $\Delta T$ . The first thought that comes to mind is to use  $\Delta T = T_s - T_{\text{avg}} = T_s - (T_i + T_e)/2$ . But this, in general, over predicts the heat transfer rate. We show in the next chapter that the proper temperature difference for internal flow (flow over tube banks is still internal flow through the shell) is the *log mean temperature difference*  $\Delta T_{\text{lm}}$  defined as

$$\Delta T_{\text{lm}} = \frac{(T_s - T_e) - (T_s - T_i)}{\ln[(T_s - T_e)/(T_s - T_i)]} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e/\Delta T_i)} \quad (7-45)$$

We also show that the exit temperature of the fluid  $T_e$  can be determined from

$$T_e = T_s - (T_s - T_i) \exp\left(-\frac{A_s h}{\dot{m} c_p}\right) \quad (7-46)$$

where  $A_s = N\pi DL$  is the heat transfer surface area and  $\dot{m} = \rho V(N_T S_T L)$  is the mass flow rate of the fluid. Here  $N$  is the total number of tubes in the bank which is the product of  $N_T$  (number of tubes in the transverse plane) and  $N_L$  (number of rows in the flow direction),  $L$  is the length of the tubes, and  $V$  is the velocity of the fluid just before entering the tube bank. Then the heat transfer rate can be determined from

$$\dot{Q} = h A_s \Delta T_{\text{lm}} = \dot{m} c_p (T_e - T_i) \quad (7-47)$$

The second relation is usually more convenient to use since it does not require the calculation of  $\Delta T_{\text{lm}}$ .

## Pressure Drop

Another quantity of interest associated with tube banks is the *pressure drop*  $\Delta P$ , which is the irreversible pressure loss between the inlet and the exit of the tube bank. It is a measure of the resistance the tubes offer to flow over them, and is expressed as

$$\Delta P = N_L f \chi \frac{\rho V_{\text{max}}^2}{2} \quad (7-48)$$

where  $f$  is the friction factor and  $\chi$  is the correction factor, both plotted in Figs. 7-27a and 7-27b against the Reynolds number based on the maximum velocity  $V_{\text{max}}$ . The friction factor in Fig. 7-27a is for a *square* in-line tube bank ( $S_T = S_L$ ), and the correction factor given in the insert is used to account for the effects of deviation of rectangular in-line arrangements from square arrangement. Similarly, the friction factor in Fig. 7-27b is for an *equilateral* staggered tube bank ( $S_T = S_D$ ), and the correction factor is to account for the effects of deviation from equilateral arrangement. Note that  $\chi = 1$  for both square and equilateral triangle arrangements. Also, pressure drop occurs in the flow direction, and thus we used  $N_L$  (the number of rows) in the  $\Delta P$  relation.

The power required to move a fluid through a tube bank is proportional to the pressure drop, and when the pressure drop is available, the pumping power required to overcome flow resistance can be determined from

$$\dot{W}_{\text{pump}} = \dot{V} \Delta P = \frac{\dot{m} \Delta P}{\rho} \quad (7-49)$$

where  $\dot{V} = V(N_T S_T L)$  is the volume flow rate and  $\dot{m} = \rho \dot{V} = \rho V(N_T S_T L)$  is the mass flow rate of the fluid through the tube bank. Note that the power required to keep a fluid flowing through the tube bank (and thus the operating cost) is proportional to the pressure drop. Therefore, the benefits of enhancing heat transfer in a tube bank via rearrangement should be weighed against the cost of additional power requirements.

In this section we limited our consideration to tube banks with base surfaces (no fins). Tube banks with finned surfaces are also commonly used in practice, especially when the fluid is a gas, and heat transfer and pressure drop correlations can be found in the literature for tube banks with pin fins, plate fins, strip fins, etc.

(a) In-line arrangement

**FIGURE 7-27**

Friction factor  $f$  and correction factor  $\chi$  for tube banks.

From Zukauskas and Ulinskas (1985).

**EXAMPLE 7-7** Preheating Air by Geothermal Water in a Tube Bank

In an industrial facility, air is to be preheated before entering a furnace by geothermal water at 120°C flowing through the tubes of a tube bank located in a duct. Air enters the duct at 20°C and 1 atm with a mean velocity of 4.5 m/s, and flows over the tubes in normal direction. The outer diameter of the tubes is 1.5 cm, and the tubes are arranged in-line with longitudinal and transverse pitches of  $S_L = S_T = 5$  cm. There are 6 rows in the flow direction with 10 tubes in each row, as shown in Fig. 7-28. Determine the rate of heat transfer per unit length of the tubes, and the pressure drop across the tube bank.

**SOLUTION** Air is heated by geothermal water in a tube bank. The rate of heat transfer to air and the pressure drop of air are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The surface temperature of the tubes is equal to the temperature of geothermal water.

**Properties** The exit temperature of air, and thus the mean temperature, is not known. We evaluate the air properties at the assumed mean temperature of 60°C (will be checked later) and 1 atm (Table A-15):

$$k = 0.02808 \text{ W/m}\cdot\text{K}$$

$$\rho = 1.059 \text{ kg/m}^3$$

$$c_p = 1.007 \text{ kJ/kg}\cdot\text{K}$$

$$\text{Pr} = 0.7202$$

$$\mu = 2.008 \times 10^{-5} \text{ kg/m}\cdot\text{s}$$

$$\text{Pr}_s = \text{Pr}_{120^\circ\text{C}} = 0.7073$$

Also, the density of air at the inlet temperature of 20°C (for use in the mass flow rate calculation at the inlet) is  $\rho_1 = 1.204 \text{ kg/m}^3$ .

**Analysis** It is given that  $D = 0.015 \text{ m}$ ,  $S_L = S_T = 0.05 \text{ m}$ , and  $V = 4.5 \text{ m/s}$ . Then the maximum velocity and the Reynolds number based on the maximum velocity become

$$V_{\max} = \frac{S_T}{S_T - D} V = \frac{0.05}{0.05 - 0.015} (4.5 \text{ m/s}) = 6.43 \text{ m/s}$$

$$\text{Re}_D = \frac{\rho V_{\max} D}{\mu} = \frac{(1.059 \text{ kg/m}^3)(6.43 \text{ m/s})(0.015 \text{ m})}{2.008 \times 10^{-5} \text{ kg/m}\cdot\text{s}} = 5086$$

The average Nusselt number is determined using the proper relation from Table 7-2 to be

$$\begin{aligned} \text{Nu}_D &= 0.27 \text{ Re}_D^{0.63} \text{ Pr}^{0.36} (\text{Pr}/\text{Pr}_s)^{0.25} \\ &= 0.27(5086)^{0.63}(0.7202)^{0.36}(0.7202/0.7073)^{0.25} = 52.1 \end{aligned}$$

This Nusselt number is applicable to tube banks with  $N_L > 16$ . In our case, the number of rows is  $N_L = 6$ , and the corresponding correction factor from Table 7-3 is  $F = 0.945$ . Then the average Nusselt number and heat transfer coefficient for all the tubes in the tube bank become

$$\text{Nu}_{D, N_{L<16}} = F \text{Nu}_D = (0.945)(52.1) = 49.3$$

FIGURE 7-28

Schematic for Example 7-7.

$$h = \frac{\text{Nu}_{D, N_{L<16}} k}{D} = \frac{49.3(0.02808 \text{ W/m}\cdot\text{K})}{0.015 \text{ m}} = 92.2 \text{ W/m}^2\cdot\text{K}$$

The total number of tubes is  $N = N_L \times N_T = 6 \times 10 = 60$ . For a unit tube length ( $L = 1 \text{ m}$ ), the heat transfer surface area and the mass flow rate of air (evaluated at the inlet) are

$$A_s = N\pi DL = 60\pi(0.015 \text{ m})(1 \text{ m}) = 2.827 \text{ m}^2$$

$$\dot{m} = \dot{m}_1 = \rho_1 V(N_T S_T L)$$

$$= (1.204 \text{ kg/m}^3)(4.5 \text{ m/s})(10)(0.05 \text{ m})(1 \text{ m}) = 2.709 \text{ kg/s}$$

Then the fluid exit temperature, the log mean temperature difference, and the rate of heat transfer become

$$T_e = T_s - (T_s - T_i) \exp\left(-\frac{A_s h}{\dot{m} c_p}\right)$$

$$= 120 - (120 - 20) \exp\left(-\frac{(2.827 \text{ m}^2)(92.2 \text{ W/m}^2\cdot\text{K})}{(2.709 \text{ kg/s})(1007 \text{ J/kg}\cdot\text{K})}\right) = 29.11^\circ\text{C}$$

$$\Delta T_{\text{lm}} = \frac{(T_s - T_e) - (T_s - T_i)}{\ln[(T_s - T_e)/(T_s - T_i)]} = \frac{(120 - 29.11) - (120 - 20)}{\ln[(120 - 29.11)/(120 - 20)]} = 95.4^\circ\text{C}$$

$$\dot{Q} = h A_s \Delta T_{\text{lm}} = (92.2 \text{ W/m}^2\cdot\text{K})(2.827 \text{ m}^2)(95.4^\circ\text{C}) = 2.49 \times 10^4 \text{ W}$$

The rate of heat transfer can also be determined in a simpler way from

$$\dot{Q} = h A_s \Delta T_{\text{lm}} = \dot{m} c_p (T_e - T_i)$$

$$= (2.709 \text{ kg/s})(1007 \text{ J/kg}\cdot\text{K})(29.11 - 20)^\circ\text{C} = 2.49 \times 10^4 \text{ W}$$

For this square in-line tube bank, the friction coefficient corresponding to  $\text{Re}_D = 5086$  and  $S_L/D = 5/1.5 = 3.33$  is, from Fig. 7-27a,  $f = 0.16$ . Also,  $\chi = 1$  for the square arrangements. Then the pressure drop across the tube bank becomes

$$\Delta P = N_L f \chi \frac{\rho V_{\text{max}}^2}{2}$$

$$= 6(0.16)(1) \frac{(1.059 \text{ kg/m}^3)(6.43 \text{ m/s})^2}{2} \left(\frac{1 \text{ N}}{1 \text{ kg}\cdot\text{m/s}^2}\right) = 21 \text{ Pa}$$

**Discussion** The arithmetic mean fluid temperature is  $(T_i + T_e)/2 = (20 + 29.11)/2 = 24.6^\circ\text{C}$ , which is not close to the assumed value of  $60^\circ\text{C}$ . Repeating calculations for  $25^\circ\text{C}$  gives  $2.57 \times 10^4 \text{ W}$  for the rate of heat transfer and 23.5 Pa for the pressure drop.

## SUMMARY

The force a flowing fluid exerts on a body in the flow direction is called *drag*. The part of drag that is due directly to wall shear stress  $\tau_w$  is called the *skin friction drag* since it is caused by frictional effects, and the part that is due directly to pressure is called the *pressure drag* or *form drag* because of its strong dependence on the form or shape of the body.

The *drag coefficient*  $C_D$  is a dimensionless number that represents the drag characteristics of a body, and is defined as

$$C_D = \frac{F_D}{\frac{1}{2}\rho V^2 A}$$

where  $A$  is the *frontal area* for blunt bodies, and surface area for parallel flow over flat plates or thin airfoils. For flow over a flat plate, the Reynolds number is

$$\text{Re}_x = \frac{\rho V x}{\mu} = \frac{V x}{\nu}$$

Transition from laminar to turbulent occurs at the *critical Reynolds number* of

$$\text{Re}_{x,\text{cr}} = \frac{\rho V x_{\text{cr}}}{\mu} = 5 \times 10^5$$

For parallel flow over a flat plate, the local friction and convection coefficients are

$$\text{Laminar: } C_{f,x} = \frac{0.664}{\text{Re}_x^{1/2}} \quad \text{Re}_x < 5 \times 10^5$$

$$\text{Nu}_x = \frac{h_x}{k} = 0.332 \text{Re}_x^{0.5} \text{Pr}^{1/3} \quad \text{Pr} > 0.6$$

*Turbulent:*

$$C_{f,x} = \frac{0.059}{\text{Re}_x^{1/5}} \quad 5 \times 10^5 \leq \text{Re}_x \leq 10^7$$

$$\text{Nu}_x = \frac{h_x}{k} = 0.0296 \text{Re}_x^{0.8} \text{Pr}^{1/3} \quad 0.6 \leq \text{Pr} \leq 60 \quad 5 \times 10^5 \leq \text{Re}_x \leq 10^7$$

The *average* friction coefficient relations for flow over a flat plate are:

$$\text{Laminar: } C_f = \frac{1.33}{\text{Re}_L^{1/2}} \quad \text{Re}_L < 5 \times 10^5$$

$$\text{Turbulent: } C_f = \frac{0.074}{\text{Re}_L^{1/5}} \quad 5 \times 10^5 \leq \text{Re}_L \leq 10^7$$

$$\text{Combined: } C_f = \frac{0.074}{\text{Re}_L^{1/5}} - \frac{1742}{\text{Re}_L} \quad 5 \times 10^5 \leq \text{Re}_L \leq 10^7$$

$$\text{Rough surface, turbulent: } C_f = \left( 1.89 - 1.62 \log \frac{\xi}{L} \right)^{-2.5}$$

The average Nusselt number relations for flow over a flat plate are:

$$\text{Laminar: } \text{Nu} = \frac{hL}{k} = 0.664 \text{Re}_L^{0.5} \text{Pr}^{1/3} \quad \begin{aligned} \text{Pr} &> 0.6 \\ \text{Re}_L &< 5 \times 10^5 \end{aligned}$$

*Turbulent:*

$$\text{Nu} = \frac{hL}{k} = 0.037 \text{Re}_L^{0.8} \text{Pr}^{1/3} \quad \begin{aligned} 0.6 &\leq \text{Pr} \leq 60 \\ 5 \times 10^5 &\leq \text{Re}_L \leq 10^7 \end{aligned}$$

*Combined:*

$$\text{Nu} = \frac{hL}{k} = (0.037 \text{Re}_L^{0.8} - 871) \text{Pr}^{1/3} \quad \begin{aligned} 0.6 &\leq \text{Pr} \leq 60 \\ 5 \times 10^5 &\leq \text{Re}_L \leq 10^7 \end{aligned}$$

For isothermal surfaces with an unheated starting section of length  $\xi$ , the local Nusselt number and the average convection coefficient relations are

$$\text{Laminar: } \text{Nu}_x = \frac{\text{Nu}_x \text{(for } \xi=0\text{)}}{[1 - (\xi/x)^{3/4}]^{1/3}} = \frac{0.332 \text{Re}_x^{0.5} \text{Pr}^{1/3}}{[1 - (\xi/x)^{3/4}]^{1/3}}$$

$$\text{Turbulent: } \text{Nu}_x = \frac{\text{Nu}_x \text{(for } \xi=0\text{)}}{[1 - (\xi/x)^{9/10}]^{1/9}} = \frac{0.0296 \text{Re}_x^{0.8} \text{Pr}^{1/3}}{[1 - (\xi/x)^{9/10}]^{1/9}}$$

$$\text{Laminar: } h = \frac{2[1 - (\xi/x)^{3/4}]}{1 - \xi/L} h_{x=L}$$

$$\text{Turbulent: } h = \frac{5[1 - (\xi/x)^{9/10}]}{(1 - \xi/L)} h_{x=L}$$

These relations are for the case of *isothermal* surfaces. When a flat plate is subjected to *uniform heat flux*, the local Nusselt number is given by

$$\text{Laminar: } \text{Nu}_x = 0.453 \text{Re}_x^{0.5} \text{Pr}^{1/3} \quad \begin{aligned} \text{Pr} &> 0.6 \\ \text{Re}_x &< 5 \times 10^5 \end{aligned}$$

$$\text{Turbulent: } \text{Nu}_x = 0.0308 \text{Re}_x^{0.8} \text{Pr}^{1/3} \quad \begin{aligned} 0.6 &\leq \text{Pr} \leq 60 \\ 5 \times 10^5 &\leq \text{Re}_x \leq 10^7 \end{aligned}$$

The average Nusselt numbers for cross flow over a *cylinder* and *sphere* are

$$\text{Nu}_{\text{cyl}} = \frac{hD}{k} = 0.3 + \frac{0.62 \text{Re}^{1/2} \text{Pr}^{1/3}}{[1 + (0.4/\text{Pr})^{2/3}]^{1/4}} \left[ 1 + \left( \frac{\text{Re}}{282,000} \right)^{5/8} \right]^{4/5}$$

which is valid for  $\text{Re Pr} > 0.2$ , and

$$\text{Nu}_{\text{sph}} = \frac{hD}{k} = 2 + [0.4 \text{Re}^{1/2} + 0.06 \text{Re}^{2/3}] \text{Pr}^{0.4} \left( \frac{\mu_{\infty}}{\mu_s} \right)^{1/4}$$

which is valid for  $3.5 \leq \text{Re} \leq 8 \times 10^4$ ,  $0.7 \leq \text{Pr} \leq 380$  and  $1.0 \leq (\mu_{\infty}/\mu_s) \leq 3.2$ . The fluid properties are evaluated at the film temperature  $T_f = (T_{\infty} + T_s)/2$  in the case of a cylinder, and at the free-stream temperature  $T_{\infty}$  (except for  $\mu_s$ , which is evaluated at the surface temperature  $T_s$ ) in the case of a sphere.

In tube banks, the Reynolds number is based on the maximum velocity  $V_{\max}$  that is related to the approach velocity  $V$  as

*In-line and Staggered* with  $S_D < (S_T + D)/2$ :

$$V_{\max} = \frac{S_T}{S_T - D} V$$

*Staggered with  $S_D < (S_T + D)/2$ :*

$$V_{\max} = \frac{S_T}{2(S_D - D)} V$$

where  $S_T$  the transverse pitch and  $S_D$  is the diagonal pitch. The average Nusselt number for cross flow over tube banks is expressed as

$$\text{Nu}_D = \frac{hD}{k} = C \text{Re}_D^m \text{Pr}^n (\text{Pr}/\text{Pr}_s)^{0.25}$$

where the values of the constants  $C$ ,  $m$ , and  $n$  depend on Reynolds number. Such correlations are given in Table 7–2. All properties except  $\text{Pr}_s$  are to be evaluated at the arithmetic mean of the inlet and exit temperatures of the fluid defined as  $T_m = (T_i + T_e)/2$ .

The average Nusselt number for tube banks with less than 16 rows is expressed as

$$\text{Nu}_{D, N_L < 16} = F \text{Nu}_D$$

where  $F$  is the *correction factor* whose values are given in Table 7–3. The heat transfer rate to or from a tube bank is determined from

$$\dot{Q} = hA_s \Delta T_{\text{lm}} = \dot{m}c_p(T_e - T_i)$$

where  $\Delta T_{\text{lm}}$  is the logarithmic mean temperature difference defined as

$$\Delta T_{\text{lm}} = \frac{(T_s - T_e) - (T_s - T_i)}{\ln[(T_s - T_e)/(T_s - T_i)]} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e/\Delta T_i)}$$

and the exit temperature of the fluid  $T_e$  is

$$T_e = T_s - (T_s - T_i) \exp \left( - \frac{A_s h}{\dot{m} c_p} \right)$$

where  $A_s = N\pi DL$  is the heat transfer surface area and  $\dot{m} = \rho V (N_T S_T L)$  is the mass flow rate of the fluid. The pressure drop  $\Delta P$  for a tube bank is expressed as

$$\Delta P = N_L f \chi \frac{\rho V_{\max}^2}{2}$$

where  $f$  is the friction factor and  $\chi$  is the correction factor, both given in Fig. 7–27.

## PROBLEMS\*

### Drag Force and Heat Transfer in External Flow

**7–1C** What is the difference between the upstream velocity and the free-stream velocity? For what types of flow are these two velocities equal to each other?

**7–2C** What is drag? What causes it? Why do we usually try to minimize it?

**7–3C** What is lift? What causes it? Does wall shear contribute to the lift?

**7–4C** During flow over a given body, the drag force, the upstream velocity, and the fluid density are measured. Explain how you would determine the drag coefficient. What area would you use in calculations?

**7–5C** Define frontal area of a body subjected to external flow. When is it appropriate to use the frontal area in drag and lift calculations?

**7–6C** What is the difference between skin friction drag and pressure drag? Which is usually more significant for slender bodies such as airfoils?

**7–7C** What is the difference between streamlined and blunt bodies? Is a tennis ball a streamlined or blunt body?

**7–8C** What is the effect of streamlining on (a) friction drag and (b) pressure drag? Does the total drag acting on a body necessarily decrease as a result of streamlining? Explain.

**7–9C** What is the effect of surface roughness on the friction drag coefficient in laminar and turbulent flows?

**7–10C** What is flow separation? What causes it? What is the effect of flow separation on the drag coefficient?

### Flow over Flat Plates

**7–11C** What does the friction coefficient represent in flow over a flat plate? How is it related to the drag force acting on the plate?

**7–12C** Consider laminar flow over a flat plate. Will the friction coefficient change with distance from the leading edge? How about the heat transfer coefficient?

**7–13C** How are the average friction and heat transfer coefficients determined in flow over a flat plate?

**7–14** Air at 25°C and 1 atm is flowing over a long flat plate with a velocity of 8 m/s. Determine the distance from the leading edge of the plate where the flow becomes turbulent, and the thickness of the boundary layer at that location.

\*Problems designated by a "C" are concept questions, and students are encouraged to answer them all. Problems designated by an "E" are in English units, and the SI users can ignore them. Problems with the icon are solved using EES, and complete solutions together with parametric studies are included on the text website. Problems with the icon are comprehensive in nature, and are intended to be solved with an equation solver such as EES. Problems with the icon are Prevention through Design problems.

**7-15** Repeat Prob. 7-14 for water.

**7-16** The weight of a thin flat plate  $40\text{ cm} \times 40\text{ cm}$  in size is balanced by a counterweight that has a mass of 2 kg, as shown in the figure. Now a fan is turned on, and air at 1 atm and  $25^\circ\text{C}$  flows downward over both surfaces of the plate with a free-stream velocity of 10 m/s. Determine the mass of the counterweight that needs to be added in order to balance the plate in this case.

FIGURE P7-16

**7-17** Air at  $15^\circ\text{C}$  and 1 atm flows over a 0.3-m-wide plate at  $65^\circ\text{C}$  at a velocity of 3.0 m/s. Compute the following quantities at  $x = 0.3\text{ m}$ :

- Hydrodynamic boundary layer thickness, m
- Local friction coefficient
- Average friction coefficient
- Total drag force due to friction, N
- Local convection heat transfer coefficient,  $\text{W}/\text{m}^2 \cdot \text{K}$
- Average convection heat transfer coefficient,  $\text{W}/\text{m}^2 \cdot \text{K}$
- Rate of convective heat transfer, W

**7-18** Engine oil at  $80^\circ\text{C}$  flows over a 10-m-long flat plate whose temperature is  $30^\circ\text{C}$  with a velocity of 2.5 m/s. Determine the total drag force and the rate of heat transfer over the entire plate per unit width.

**7-19E** Air at  $60^\circ\text{F}$  flows over a 10-ft-long flat plate at 7 ft/s. Determine the local friction and heat transfer coefficients at intervals of 1 ft, and plot the results against the distance from the leading edge.

**7-20E**  Reconsider Prob. 7-19E. Using EES (or other) software, evaluate the local friction and heat transfer coefficients along the plate at intervals of 0.1 ft, and plot them against the distance from the leading edge.

**7-21** Consider laminar flow of a fluid over a flat plate maintained at a constant temperature. Now the free-stream velocity of the fluid is doubled. Determine the change in the drag force on the plate and rate of heat transfer between the fluid and the plate. Assume the flow to remain laminar.

**7-22** In an experiment, the local heat transfer over a flat plate were correlated in the form of local Nusselt number as expressed by the following correlation

$$\text{Nu}_x = 0.035 \text{Re}_x^{0.8} \text{Pr}^{1/3}$$

Determine the ratio of the average convection heat transfer coefficient ( $h$ ) over the entire plate length to the local convection heat transfer coefficient ( $h_x$ ) at  $x = L$ .

**7-23** Water at  $43.3^\circ\text{C}$  flows over a large plate at a velocity of 30.0 cm/s. The plate is 1.0 m long (in the flow direction), and its surface is maintained at a uniform temperature of  $10.0^\circ\text{C}$ . Calculate the steady rate of heat transfer per unit width of the plate.

**7-24** The forming section of a plastics plant puts out a continuous sheet of plastic that is 1.2 m wide and 2 mm thick at a rate of 15 m/min. The temperature of the plastic sheet is  $90^\circ\text{C}$  when it is exposed to the surrounding air, and the sheet is subjected to air flow at  $30^\circ\text{C}$  at a velocity of 3 m/s on both sides along its surfaces normal to the direction of motion of the sheet. The width of the air cooling section is such that a fixed point on the plastic sheet passes through that section in 2 s. Determine the rate of heat transfer from the plastic sheet to the air.

FIGURE P7-24

**7-25** Hot carbon dioxide exhaust gas at 1 atm is being cooled by flat plates. The gas at  $220^\circ\text{C}$  flows in parallel over the upper and lower surfaces of a 1.5-m-long flat plate at a velocity of 3 m/s. If the flat plate surface temperature is maintained at  $80^\circ\text{C}$ , determine (a) the local convection heat transfer coefficient at 1 m from the leading edge, (b) the average convection heat transfer coefficient over the entire plate, and (c) the total heat flux transfer to the plate.

**7-26** A transformer that is 10 cm long, 6.2 cm wide, and 5 cm high is to be cooled by attaching a 10-cm  $\times$  6.2-cm-wide polished aluminum heat sink (emissivity = 0.03) to its top surface. The heat sink has seven fins, which are 5 mm high,

2 mm thick, and 10 cm long. A fan blows air at 25°C parallel to the passages between the fins. The heat sink is to dissipate 12 W of heat and the base temperature of the heat sink is not to exceed 60°C. Assuming the fins and the base plate to be nearly isothermal and the radiation heat transfer to be negligible, determine the minimum free-stream velocity the fan needs to supply to avoid overheating. Assume the flow is laminar over the entire finned surface of the transformer.

**FIGURE P7–26**

**7–27** Repeat Prob. 7–26 assuming the heat sink to be black-anodized and thus to have an effective emissivity of 0.90. Note that in radiation calculations the base area ( $10\text{ cm} \times 6.2\text{ cm}$ ) is to be used, not the total surface area.

**7–28** Hot engine oil at 150°C is flowing in parallel over a flat plate at a velocity of 2 m/s. Surface temperature of the 0.5-m-long flat plate is constant at 50°C. Determine (a) the local convection heat transfer coefficient at 0.2 m from the leading edge and the average convection heat transfer coefficient, and (b) repeat part (a) using the Churchill and Ozoe (1973) relation.

**7–29** Parallel plates form a solar collector that covers a roof, as shown in the figure. The plates are maintained at 15°C, while ambient air at 10°C flows over the roof with  $V = 2\text{ m/s}$ . Determine the rate of convective heat loss from (a) the first plate and (b) the third plate.

**FIGURE P7–29**

**7–30** Hydrogen gas at 1 atm is flowing in parallel over the upper and lower surfaces of a 3-m-long flat plate at a velocity of 2.5 m/s. The gas temperature is 120°C and the surface temperature of the plate is maintained at 30°C. Using the EES (or other) software, investigate the local convection heat transfer coefficient and the local total convection heat flux along the plate. By varying the location along the plate for  $0.2 \leq x \leq 3\text{ m}$ , plot the local convection heat transfer coefficient and the local total convection heat flux as functions of  $x$ . Assume flow is laminar but make sure to verify this assumption.

**7–31** Carbon dioxide and hydrogen as ideal gases at 1 atm and -20°C flow in parallel over a flat plate. The flow velocity of each gas is 1 m/s and the surface temperature of the 3-m-long plate is maintained at 20°C. Using the EES (or other) software, evaluate the local Reynolds number, the local Nusselt number, and the local convection heat transfer coefficient along the plate for each gas. By varying the location along the plate for  $0.2 \leq x \leq 3\text{ m}$ , plot the local Reynolds number, the local Nusselt number, and the local convection heat transfer coefficient for each gas as functions of  $x$ . Discuss which gas has higher local Nusselt number and which gas has higher convection heat transfer coefficient along the plate. Assume flow is laminar but make sure to verify this assumption.

**7–32** An array of power transistors, dissipating 6 W of power each, are to be cooled by mounting them on a 25-cm  $\times$  25-cm-square aluminum plate and blowing air at 35°C over the plate with a fan at a velocity of 4 m/s. The average temperature of the plate is not to exceed 65°C. Assuming the heat transfer from the back side of the plate to be negligible and disregarding radiation, determine the number of transistors that can be placed on this plate.

**FIGURE P7–32**

**7–33** Repeat Prob. 7–32 for a location at an elevation of 1610 m where the atmospheric pressure is 83.4 kPa. *Answer: 4*

**7-34E** Consider a refrigeration truck traveling at 55 mph at a location where the air temperature is 80°F. The refrigerated compartment of the truck can be considered to be a 9-ft-wide, 8-ft-high, and 20-ft-long rectangular box. The refrigeration system of the truck can provide 3 tons of refrigeration (i.e., it can remove heat at a rate of 600 Btu/min). The outer surface of the truck is coated with a low-emissivity material, and thus radiation heat transfer is very small. Determine the average temperature of the outer surface of the refrigeration compartment of the truck if the refrigeration system is observed to be operating at half the capacity. Assume the air flow over the entire outer surface to be turbulent and the heat transfer coefficient at the front and rear surfaces to be equal to that on side surfaces. For air properties evaluations assume a film temperature of 80°F. Is this a good assumption?

FIGURE P7-34E

**7-35** Consider a hot automotive engine, which can be approximated as a 0.5-m-high, 0.40-m-wide, and 0.8-m-long rectangular block. The bottom surface of the block is at a temperature of 100°C and has an emissivity of 0.95. The ambient air is at 20°C, and the road surface is at 25°C. Determine the rate of heat transfer from the bottom surface of the engine block by convection and radiation as the car travels at a velocity of 80 km/h. Assume the flow to be turbulent over the entire surface because of the constant agitation of the engine block.

**7-36** Air at 1 atm is flowing in parallel over a 3-m-long flat plate with a velocity of 7 m/s. The air has a free stream temperature of 120°C and the surface temperature of the plate is maintained at 20°C. Determine the distance  $x$  from the leading edge of the plate where the critical Reynolds number ( $Re_{cr} = 5 \times 10^5$ ) is reached. Then, using the EES (or other) software, evaluate the local convection heat transfer coefficient along the plate. By varying the location along the plate for  $0.2 \leq x \leq 3$  m, plot the local convection heat transfer coefficient as a function of  $x$ , and discuss the results.

**7-37** Heat dissipated from a machine in operation can cause hot spots on its surface. Exposed hot spots that are a potential to cause thermal burns on human

skin tissue are considered to be hazards in the workplace. Consider a 1.5 m × 1.5 m flat machine surface that is made of a 5-mm-thick aluminum ( $k = 237 \text{ W/m}\cdot\text{K}$ ). During operation the machine inner aluminum surface temperature can be as high as 90°C, while the outer surface is cooled with 30°C air flowing in parallel over it at 10 m/s. To prevent machine operators from thermal burns, the machine surface can be covered with insulation. The aluminum/insulation interface has a thermal contact conductance of 3000 W/m<sup>2</sup>·K. What is the thickness required of the insulation layer, with a thermal conductivity of 0.06 W/m·K, in order to maintain the local outer surface temperature at 45°C or lower? Using the EES (or other) software, plot the required insulation thickness and the local convection heat transfer coefficient along the outer surface in parallel with the air flow.

FIGURE P7-37

**7-38** Air at 1 atm and 20°C is flowing over the top surface of a 0.5-m-long thin flat plate. The air stream velocity is 50 m/s and the plate is maintained at a constant surface temperature of 180°C. Determine (a) the average friction coefficient, (b) the average convection heat transfer coefficient, and (c) repeat part (b) using the modified Reynolds analogy.

FIGURE P7-38

**7-39** A 5-m-long strip of sheet metal is being transported on a conveyor at a velocity of 5 m/s, while the coating on the upper surface is being cured by infrared lamps. The coating on the upper surface of the metal strip has an absorptivity of 0.6 and an emissivity of 0.7, while the surrounding ambient air temperature is 25°C. Radiation heat transfer occurs only on the upper surface, while convection heat transfer occurs on both upper and lower surfaces of the sheet metal. If the infrared lamps supply a constant heat flux of 5000 W/m<sup>2</sup>, determine the surface temperature of the sheet metal. Evaluate the properties of air at 80°C.

FIGURE P7-39

- 7-40** Reconsider Prob. 7-39. Using the EES (or other) software, evaluate the effect of the sheet metal velocity on its surface temperature. By varying the sheet metal velocity from 3 to 30 m/s, plot the surface temperature of the sheet metal as a function of velocity. If the surface temperature of the sheet metal should be maintained above 100°C, determine the minimum velocity that is necessary to satisfy this condition. Evaluate the properties of air at 80°C.

**7-41** The local atmospheric pressure in Denver, Colorado (elevation 1610 m), is 83.4 kPa. Air at this pressure and at 30°C flows with a velocity of 6 m/s over a 2.5-m × 8-m flat plate whose temperature is 120°C. Determine the rate of heat transfer from the plate if the air flows parallel to the (a) 8-m-long side and (b) the 2.5 m side.

**7-42** During a cold winter day, wind at 55 km/h is blowing parallel to a 4-m-high and 10-m-long wall of a house. If the air outside is at 5°C and the surface temperature of the wall is 12°C, determine the rate of heat loss from that wall by convection. What would your answer be if the wind velocity was doubled? *Answers: 9.08 kW, 16.2 kW*

FIGURE P7-42

- 7-43** Reconsider Prob. 7-42. Using EES (or other) software, investigate the effects of wind velocity and outside air temperature on the rate of heat loss from the wall by convection. Let the wind velocity vary from 10 km/h to 80 km/h and the outside air temperature from 0°C to 10°C. Plot the rate of heat loss as a function of the wind velocity and of the outside temperature, and discuss the results.

**7-44E** Warm air is blown over the inner surface of an automobile windshield to defrost ice accumulated on the outer surface of the windshield. Consider an automobile windshield ( $k_w = 0.8 \text{ Btu/h}\cdot\text{ft}\cdot\text{R}$ ) with an overall height of 20 in and thickness of 0.2 in. The outside air (1 atm) ambient temperature is 8°F and the

average airflow velocity over the outer windshield surface is 50 mph, while the ambient temperature inside the automobile is 77°F. Determine the value of the convection heat transfer coefficient for the warm air blowing over the inner surface of the windshield, necessary to cause the accumulated ice to begin melting. Assume the windshield surface can be treated as a flat plate surface.

- 7-45** The top surface of the passenger car of a train moving at a velocity of 70 km/h is 2.8 m wide and 8 m long. The top surface is absorbing solar radiation at a rate of 200 W/m<sup>2</sup>, and the temperature of the ambient air is 30°C. Assuming the roof of the car to be perfectly insulated and the radiation heat exchange with the surroundings to be small relative to convection, determine the equilibrium temperature of the top surface of the car. *Answer: 35.1°C*

FIGURE P7-45

- 7-46** Reconsider Prob. 7-45. Using EES (or other) software, investigate the effects of the train velocity and the rate of absorption of solar radiation on the equilibrium temperature of the top surface of the car. Let the train velocity vary from 10 km/h to 120 km/h and the rate of solar absorption from 100 W/m<sup>2</sup> to 500 W/m<sup>2</sup>. Plot the equilibrium temperature as functions of train velocity and solar radiation absorption rate, and discuss the results.

**7-47** Solar radiation is incident on the glass cover of a solar collector at a rate of 700 W/m<sup>2</sup>. The glass transmits 88 percent of the incident radiation and has an emissivity of 0.90. The entire hot water needs of a family in summer can be met by two collectors 1.2 m high and 1 m wide. The two collectors are attached to each other on one side so that they appear like a single collector 1.2 m × 2 m in size. The temperature of the glass cover is measured to be 35°C on a day when the surrounding air temperature is 25°C and the wind is blowing at 30 km/h. The effective sky temperature for radiation exchange between the glass cover and the open sky is -40°C. Water enters the tubes attached to the absorber plate at a rate of 1 kg/min. Assuming the back surface of the absorber plate to be heavily insulated and the only heat loss to occur through the glass cover, determine (a) the total rate of heat loss from the collector, (b) the collector efficiency,

which is the ratio of the amount of heat transferred to the water to the solar energy incident on the collector, and (c) the temperature rise of water as it flows through the collector.

$$T_{\text{sky}} = -40^{\circ}\text{C}$$

**FIGURE P7–47**

- 7–48** **PtD** Reconsider Example 7–2. Another method that could be explored to keep the engine outer surface temperature below the fire hazard limit of  $180^{\circ}\text{C}$  is to increase the insulation thickness. Increase the insulation thickness by threefold and verify if this meted would keep the temperature below the required limit for the safe operation of the engine. Compare the effectiveness of this method with the one used in Example 7–2.

- 7–49** **PtD** The outer surface of an engine is situated in a place where oil leakage can occur. When leaked oil comes in contact with a hot surface that has a temperature above its autoignition temperature, the oil can ignite spontaneously. Consider an engine cover that is made of a stainless steel plate with a thickness of 1 cm and a thermal conductivity of  $14 \text{ W/m}\cdot\text{K}$ . The inner surface of the engine cover is exposed to hot air with a convection heat transfer coefficient of  $7 \text{ W/m}^2\cdot\text{K}$  at a temperature of  $333^{\circ}\text{C}$ . The engine outer surface is cooled by air blowing in parallel over the 2-m-long surface at  $7.1 \text{ m/s}$ , in an environment where the ambient air is at  $60^{\circ}\text{C}$ . To prevent fire hazard in the event of oil leak on the engine cover, a layer of thermal barrier coating (TBC) with a thermal conductivity of  $1.1 \text{ W/m}\cdot\text{K}$  is applied on the engine cover outer surface. Would a TBC layer with a thickness of 4 mm in conjunction with  $7.1 \text{ m/s}$  air cooling be sufficient to keep the engine cover surface from going above  $180^{\circ}\text{C}$  to prevent fire hazard? Evaluate the air properties at  $120^{\circ}\text{C}$ .

- 7–50** **PtD** Metal plates ( $k = 180 \text{ W/m}\cdot\text{K}$ ,  $\rho = 2800 \text{ kg/m}^3$ , and  $c_p = 880 \text{ J/kg}\cdot\text{K}$ ) with a length of 1 m and a thickness of 2 cm exiting an oven are then conveyed through a 10-m-long cooling chamber at a speed of  $5 \text{ mm/s}$ . The plates enter the cooling chamber at an initial temperature of  $155^{\circ}\text{C}$ . In the cooling chamber, the plates are cooled with  $10^{\circ}\text{C}$  air blowing in parallel over them. To prevent any incident of thermal burn, it is necessary to design the cooling process such that the plates exit the cooling chamber at a relatively safe

temperature. Determine the air velocity such that the temperature of the plates exiting the cooling chamber is  $45^{\circ}\text{C}$  or less. Assume combined laminar and turbulent flow (verify this assumption). Hint: Use the lumped system analysis to determine the required cooling time (verify application of this method to this problem).

**FIGURE P7–50**

- 7–51** Mercury at  $25^{\circ}\text{C}$  flows over a 3-m-long and 2-m-wide flat plate maintained at  $75^{\circ}\text{C}$  with a velocity of  $0.8 \text{ m/s}$ . Determine the rate of heat transfer from the entire plate.

**FIGURE P7–51**

- 7–52** Liquid mercury at  $250^{\circ}\text{C}$  is flowing in parallel over a flat plate at a velocity of  $0.3 \text{ m/s}$ . Surface temperature of the 0.1-m-long flat plate is constant at  $50^{\circ}\text{C}$ . Determine (a) the local convection heat transfer coefficient at 5 cm from the leading edge and (b) the average convection heat transfer coefficient over the entire plate.

- 7–53** Liquid mercury at  $250^{\circ}\text{C}$  is flowing with a velocity of  $0.3 \text{ m/s}$  in parallel over a 0.1-m-long flat plate where there is an unheated starting length of 5 cm. The heated section of the flat plate is maintained at a constant temperature of  $50^{\circ}\text{C}$ . Determine (a) the local convection heat transfer coefficient at the trailing edge, (b) the average convection heat transfer coefficient for the heated section, and (c) the rate of heat transfer per unit width for the heated section.

**7-54** A  $15 \text{ mm} \times 15 \text{ mm}$  silicon chip is mounted such that the edges are flush in a substrate. The chip dissipates  $1.4 \text{ W}$  of power uniformly, while air at  $20^\circ\text{C}$  (1 atm) with a velocity of  $25 \text{ m/s}$  is used to cool the upper surface of the chip. If the substrate provides an unheated starting length of  $15 \text{ mm}$ , determine the surface temperature at the trailing edge of the chip. Evaluate the air properties at  $50^\circ\text{C}$ .

**7-55** The upper surface of a metal plate is being cooled with parallel air flow while its lower surface is subjected to a uniform heat flux of  $810 \text{ W/m}^2$ . The air has a free stream velocity and temperature of  $2.5 \text{ m/s}$  and  $15^\circ\text{C}$ , respectively. Determine the surface temperature of the plate at  $x = 1.5 \text{ m}$  from the leading edge. Hint: The surface temperature has to be found iteratively. Start the iteration process with an initial guess of  $45^\circ\text{C}$  for the surface temperature.

FIGURE P7-55

**7-56** Reconsider Prob. 7-55. Using the EES (or other) software, evaluate the local convection heat transfer coefficient, the local surface temperature, and the local film temperature along the plate. By varying the location along the plate for  $0.2 \leq x \leq 3 \text{ m}$ , plot the local convection heat transfer coefficient, the local surface temperature, and the local film temperature as function of  $x$ .

**7-57** Air is flowing in parallel over the upper surface of a flat plate with a length of  $4 \text{ m}$ . The first half of the plate length, from the leading edge, has a constant surface temperature of  $50^\circ\text{C}$ . The second half of the plate length is subjected to a uniform heat flux of  $86 \text{ W/m}^2$ . The air has a free stream velocity and temperature of  $2 \text{ m/s}$  and  $10^\circ\text{C}$ , respectively. Determine the local convection heat transfer coefficients at  $1 \text{ m}$  and  $3 \text{ m}$  from the leading edge. Evaluate the air properties at a film temperature of  $30^\circ\text{C}$ . Is the film temperature  $T_f = 30^\circ\text{C}$  applicable at  $x = 3 \text{ m}$ ?

FIGURE P7-57

**7-58** Reconsider Prob. 7-57. Using the EES (or other) software, evaluate the local convection heat transfer coefficient, the local surface temperature, and the local film temperature along the plate. By varying the location along the plate for  $0.2 \leq x \leq 4 \text{ m}$ , plot the local convection heat transfer coefficient, the local surface temperature, and the local film temperature as function of  $x$ .

**7-59** A  $15\text{-cm} \times 15\text{-cm}$  circuit board dissipating  $20 \text{ W}$  of power uniformly is cooled by air, which approaches the circuit board at  $20^\circ\text{C}$  with a velocity of  $6 \text{ m/s}$ . Disregarding any heat transfer from the back surface of the board, determine the surface temperature of the electronic components (a) at the leading edge and (b) at the end of the board. Assume the flow to be turbulent since the electronic components are expected to act as turbulators. For air properties evaluations assume a film temperature of  $35^\circ\text{C}$ . Is this a good assumption?

### Flow across Cylinders and Spheres

**7-60C** In flow over blunt bodies such as a cylinder, how does the pressure drag differ from the friction drag?

**7-61C** In flow over cylinders, why does the drag coefficient suddenly drop when the flow becomes turbulent? Isn't turbulence supposed to increase the drag coefficient instead of decreasing it?

**7-62C** Why is flow separation in flow over cylinders delayed in turbulent flow?

**7-63C** Consider laminar flow of air across a hot circular cylinder. At what point on the cylinder will the heat transfer be highest? What would your answer be if the flow were turbulent?

**7-64** Consider the flow of a fluid across a cylinder maintained at a constant temperature. Now the free-stream velocity of the fluid is doubled. Determine the change in the drag force on the cylinder and the rate of heat transfer between the fluid and the cylinder.

**7-65** A long  $8\text{-cm}$ -diameter steam pipe whose external surface temperature is  $90^\circ\text{C}$  passes through some open area that is not protected against the winds. Determine the rate of heat loss from the pipe per unit of its length when the air is at  $1 \text{ atm}$  pressure and  $7^\circ\text{C}$  and the wind is blowing across the pipe at a velocity of  $50 \text{ km/h}$ .

**7-66** A heated long cylindrical rod is placed in a cross flow of air at  $20^\circ\text{C}$  (1 atm) with velocity of  $10 \text{ m/s}$ . The rod has a diameter of  $5 \text{ mm}$  and its surface has an emissivity of  $0.95$ . If the surrounding temperature is  $20^\circ\text{C}$  and the heat flux dissipated from the rod is  $16000 \text{ W/m}^2$ , determine the surface temperature of the rod. Evaluate the air properties at  $70^\circ\text{C}$ .

**7-67E** A person extends his uncovered arms into the windy air outside at  $54^\circ\text{F}$  and  $20 \text{ mph}$  in order to feel nature closely (see Fig. P7-67E on the next page). Initially, the skin temperature of the arm is  $86^\circ\text{F}$ . Treating the arm as a  $2\text{-ft-long}$  and  $3\text{-in-diameter}$  cylinder, determine the rate of heat loss from the arm.

FIGURE P7-67E

**7-68E** Reconsider Prob. 7-67E. Using EES (or other) software, investigate the effects of air temperature and wind velocity on the rate of heat loss from the arm. Let the air temperature vary from 20°F to 80°F and the wind velocity from 10 mph to 40 mph. Plot the rate of heat loss as a function of air temperature and of wind velocity, and discuss the results.

**7-69** In a geothermal power plant, the used geothermal water at 80°C enters a 15-cm-diameter and 400-m-long uninsulated pipe at a rate of 8.5 kg/s and leaves at 70°C before being reinjected back to the ground. Windy air at 15°C flows normal to the pipe. Disregarding radiation, determine the average wind velocity in km/h.

FIGURE P7-69

**7-70** A 6-mm-diameter electrical transmission line carries an electric current of 50 A and has a resistance of 0.002 ohm per meter length. Determine the surface temperature of the wire during a windy day when the air temperature is 10°C and the wind is blowing across the transmission line at 40 km/h.

FIGURE P7-70

**7-71** Reconsider Prob. 7-70. Using EES (or other) software, investigate the effect of the wind velocity on the surface temperature of the wire. Let the wind velocity vary from 10 km/h to 80 km/h. Plot the surface temperature as a function of wind velocity, and discuss the results.

**7-72** A long aluminum wire of diameter 3 mm is extruded at a temperature of 280°C. The wire is subjected to cross air flow at 20°C at a velocity of 6 m/s. Determine the rate of heat transfer from the wire to the air per meter length when it is first exposed to the air.

FIGURE P7-72

**7-73E** Consider a person who is trying to keep cool on a hot summer day by turning a fan on and exposing his entire body to air flow. The air temperature is 85°F and the fan is blowing air at a velocity of 6 ft/s. If the person is doing light work and generating sensible heat at a rate of 300 Btu/h, determine the average temperature of the outer surface (skin or clothing) of the person. The average human body can be treated as a 1-ft-diameter cylinder with an exposed surface area of 18 ft<sup>2</sup>. Disregard any heat transfer by radiation. What would your answer be if the air velocity were doubled? Evaluate the air properties at 100°F.

Answers: 95.1°F, 91.6°F

FIGURE P7-73

**7-74E** A 12-ft-long, 1.5-kW electrical resistance wire is made of 0.1-in-diameter stainless steel ( $k = 8.7 \text{ Btu/h}\cdot\text{ft}\cdot^\circ\text{F}$ ). The resistance wire operates in an environment at 85°F. Determine the surface temperature of the wire if it is cooled

by a fan blowing air at a velocity of 20 ft/s. For evaluations of the air properties, the film temperature has to be found iteratively. As an initial guess, assume the film temperature to be 200°F.

FIGURE P7-74E

**7-75** A 0.4-W cylindrical electronic component with diameter 0.3 cm and length 1.8 cm and mounted on a circuit board is cooled by air flowing across it at a velocity of 240 m/min. If the air temperature is 35°C, determine the surface temperature of the component. For air properties evaluations assume a film temperature of 50°C. Is this a good assumption?

**7-76** Consider a 50-cm-diameter and 95-cm-long hot water tank. The tank is placed on the roof of a house. The water inside the tank is heated to 80°C by a flat-plate solar collector during the day. The tank is then exposed to windy air at 18°C with an average velocity of 40 km/h during the night. Estimate the temperature of the tank after a 45-min period. Assume the tank surface to be at the same temperature as the water inside, and the heat transfer coefficient on the top and bottom surfaces to be the same as that on the side surface. Evaluate the air properties at 50°C.

**7-77** Reconsider Prob. 7-76. Using EES (or other) software, plot the temperature of the tank as a function of the cooling time as the time varies from 30 min to 5 h, and discuss the results.

**7-78** During a plant visit, it was noticed that a 12-m-long section of a 10-cm-diameter steam pipe is completely exposed to the ambient air. The temperature measurements indicate that the average temperature of the outer surface of the steam pipe is 75°C when the ambient temperature is 5°C. There are also light winds in the area at 10 km/h. The emissivity of the outer surface of the pipe is 0.8, and the average temperature of the surfaces surrounding the pipe, including the sky, is estimated to be 0°C. Determine the amount of heat lost from the steam during a 10-h-long work day.

Steam is supplied by a gas-fired steam generator that has an efficiency of 80 percent, and the plant pays \$1.05/therm of natural gas. If the pipe is insulated and 90 percent of the heat loss is saved, determine the amount of money this facility will save a year as a result of insulating the steam pipes. Assume the plant operates every day of the year for 10 h. State your assumptions.

FIGURE P7-78

**7-79** Reconsider Prob. 7-78. There seems to be some uncertainty about the average temperature of the surfaces surrounding the pipe used in radiation calculations, and you are asked to determine if it makes any significant difference in overall heat transfer. Repeat the calculations for average surrounding and surface temperatures of -20°C and 25°C, respectively, and determine the change in the values obtained.

**7-80** A 10-cm-diameter, 30-cm-high cylindrical bottle contains cold water at 3°C. The bottle is placed in windy air at 27°C. The water temperature is measured to be 11°C after 45 min of cooling. Disregarding radiation effects and heat transfer from the top and bottom surfaces, estimate the average wind velocity.

**7-81** Exhaust gases from a manufacturing plant are being discharged through a 10-m-tall exhaust stack with outer diameter of 1 m. The exhaust gases are discharged at a rate of 1.2 kg/s, while temperature drop between inlet and exit of the exhaust stack is 30°C, and the constant pressure specific heat of the exhaust gasses is 1600 J/kg·K. On a particular day, wind at 27°C is blowing across the exhaust stack with a velocity of 10 m/s, while the outer surface of the exhaust stack experiences radiation with the surrounding at 27°C. Solar radiation is incident on the exhaust stack outer surface at a rate of 1400 W/m<sup>2</sup>, and both the emissivity and solar absorptivity of the outer surface are 0.9. Determine the exhaust stack outer surface temperature. Evaluate the air properties at 80°C.

FIGURE P7-81

**7-82**   Exposure to high concentration of gaseous ammonia can cause lung damage. To prevent gaseous ammonia from leaking out, ammonia is transported in its liquid state through a pipe ( $k = 25 \text{ W/m}\cdot\text{K}$ ,  $D_{i,\text{pipe}} = 2.5 \text{ cm}$ ,  $D_{o,\text{pipe}} = 4 \text{ cm}$ , and  $L = 10 \text{ m}$ ). Since liquid ammonia has a normal boiling point of  $-33.3^\circ\text{C}$ , the pipe needs to be properly insulated to prevent the surrounding heat from causing the ammonia to boil. The pipe is situated in a laboratory, where air at  $20^\circ\text{C}$  is blowing across it with a velocity of  $7 \text{ m/s}$ . The convection heat transfer coefficient of the liquid ammonia is  $100 \text{ W/m}^2\cdot\text{K}$ . Calculate the minimum insulation thickness for the pipe using a material with  $k = 0.75 \text{ W/m}\cdot\text{K}$  to keep the liquid ammonia flowing at an average temperature of  $-35^\circ\text{C}$ , while maintaining the insulated pipe outer surface temperature at  $10^\circ\text{C}$ .

**7-83**   Ice slurry is being transported in a pipe ( $k = 15 \text{ W/m}\cdot\text{K}$ ,  $D_i = 2.5 \text{ cm}$ ,  $D_o = 3 \text{ cm}$ , and  $L = 5 \text{ m}$ ) with an inner surface temperature of  $0^\circ\text{C}$ . The ambient condition surrounding the pipe has a temperature of  $20^\circ\text{C}$  and a dew point at  $10^\circ\text{C}$ . A blower is located near the pipe, which provides blowing air across the pipe at a velocity of  $2 \text{ m/s}$ . If the outer surface temperature of the pipe drops below the dew point, condensation can occur on the surface. Since this pipe is located in a vicinity of high voltage devices, water droplets from the condensation can cause electrical hazard. To prevent such incident, the pipe surface needs to be insulated. Calculate the minimum insulation thickness for the pipe using a material with  $k = 0.95 \text{ W/m}\cdot\text{K}$  to prevent the outer surface temperature from dropping below the dew point.

**7-84** Air at  $20^\circ\text{C}$  (1 atm) is flowing over a 5-cm diameter sphere with a velocity of  $3.5 \text{ m/s}$ . If the surface temperature of the sphere is constant at  $80^\circ\text{C}$ , determine (a) the average drag coefficient on the sphere and (b) the heat transfer rate from the sphere.

**7-85** A stainless steel ball ( $\rho = 8055 \text{ kg/m}^3$ ,  $c_p = 480 \text{ J/kg}\cdot\text{K}$ ) of diameter  $D = 15 \text{ cm}$  is removed from the oven at a uniform temperature of  $350^\circ\text{C}$ . The ball is then subjected to the flow of air at 1 atm pressure and  $30^\circ\text{C}$  with a velocity of  $6 \text{ m/s}$ . The surface temperature of the ball eventually drops to  $250^\circ\text{C}$ . Determine the average convection heat transfer coefficient during this cooling process and estimate how long this process has taken.

**7-86**  Reconsider Prob. 7-85. Using EES (or other) software, investigate the effect of air velocity on the average convection heat transfer coefficient and the cooling time. Let the air velocity vary from  $1 \text{ m/s}$  to  $10 \text{ m/s}$ . Plot the heat transfer coefficient and the cooling time as a function of air velocity, and discuss the results.

**7-87** An average person generates heat at a rate of  $84 \text{ W}$  while resting. Assuming one-quarter of this heat is lost from the head and disregarding radiation, determine the average surface temperature of the head when it is not covered and is subjected to winds at  $10^\circ\text{C}$  and  $25 \text{ km/h}$ . The head can be

approximated as a 30-cm-diameter sphere. Assume a surface temperature of  $15^\circ\text{C}$  for evaluation of  $\mu_s$ . Is this a good assumption? *Answer:  $13.2^\circ\text{C}$*

**7-88** An incandescent lightbulb is an inexpensive but highly inefficient device that converts electrical energy into light. It converts about 10 percent of the electrical energy it consumes into light while converting the remaining 90 percent into heat. (A fluorescent lightbulb will give the same amount of light while consuming only one-fourth of the electrical energy, and it will last 10 times longer than an incandescent lightbulb.) The glass bulb of the lamp heats up very quickly as a result of absorbing all that heat and dissipating it to the surroundings by convection and radiation.

Consider a 10-cm-diameter  $100 \text{ W}$  lightbulb cooled by a fan that blows air at  $30^\circ\text{C}$  to the bulb at a velocity of  $2 \text{ m/s}$ . The surrounding surfaces are also at  $30^\circ\text{C}$ , and the emissivity of the glass is 0.9. Assuming 10 percent of the energy passes through the glass bulb as light with negligible absorption and the rest of the energy is absorbed and dissipated by the bulb itself, determine the equilibrium temperature of the glass bulb. Assume a surface temperature of  $100^\circ\text{C}$  for evaluation of  $\mu_s$ . Is this a good assumption?

FIGURE P7-88

**7-89** A 1.8-m-diameter spherical tank of negligible thickness contains iced water at  $0^\circ\text{C}$ . Air at  $25^\circ\text{C}$  flows over the tank with a velocity of  $7 \text{ m/s}$ . Determine the rate of heat transfer to the tank and the rate at which ice melts. The heat of fusion of water at  $0^\circ\text{C}$  is  $333.7 \text{ kJ/kg}$ .

**7-90**  In an experiment, the temperature of a hot air stream is to be measured by a thermocouple with a spherical junction. Due to the nature of this experiment, the response time of the thermocouple to register 99 percent of the initial temperature difference must be within  $5 \text{ s}$ . The properties of the thermocouple junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ . The hot air has a free stream velocity and temperature of  $3 \text{ m/s}$  and  $140^\circ\text{C}$ , respectively. If the initial temperature of the thermocouple junction is  $20^\circ\text{C}$ , determine the thermocouple junction diameter that would satisfy the required response time of  $5 \text{ s}$ . *Hint: Use the lumped system analysis to determine the time required for the thermocouple to register 99 percent of the*

initial temperature difference (verify application of this method to this problem).

**FIGURE P7–90**

- 7–91** Reconsider Prob. 7–90. Using the EES (or other) software, evaluate the effect of the hot air velocity on the thermocouple junction diameter that would satisfy the required response time of 5 s. By varying the hot air velocity from 1 to 10 m/s, plot the thermocouple junction diameter as a function of air velocity.

- 7–92** A thermocouple with a spherical junction diameter of 1 mm is used for measuring the temperature of a hydrogen gas stream. The properties of the thermocouple junction are  $k = 35 \text{ W/m}\cdot\text{K}$ ,  $\rho = 8500 \text{ kg/m}^3$ , and  $c_p = 320 \text{ J/kg}\cdot\text{K}$ . The hydrogen gas, behaving as an ideal gas at 1 atm, has a free stream temperature of 200°C. If the initial temperature of the thermocouple junction is 10°C, evaluate the time for the thermocouple to register 99 percent of the initial temperature difference at different free stream velocities of the hydrogen gas. Using the EES (or other) software, perform the evaluation by varying the free stream velocity from 1 to 100 m/s. Then, plot the thermocouple response time and the convection heat transfer coefficient as a function of free stream velocity. Hint: Use the lumped system analysis to determine the time required for the thermocouple to register 99 percent of the initial temperature difference (verify application of this method to this problem).

**FIGURE P7–92**

- 7–93** A glass ( $k = 1.1 \text{ W/m}\cdot\text{K}$ ) spherical tank is filled with chemicals undergoing exothermic reaction. The reaction keeps the inner surface temperature of the tank at 80°C. The tank has an inner radius of 0.5 m and its wall thickness is 10 mm. Situated in surroundings with an ambient temperature of 15°C and a convection heat transfer

coefficient of 70 W/m<sup>2</sup>·K, the tank's outer surface is being cooled by air flowing across it at 5 m/s. In order to prevent thermal burn on individuals working around the container, it is necessary to keep the tank's outer surface temperature below 50°C. Determine whether or not the tank's outer surface temperature is safe from thermal burn hazards.

**FIGURE P7–93**

- 7–94** The components of an electronic system are located in a 1.5-m-long horizontal duct whose cross section is 20 cm × 20 cm. The components in the duct are not allowed to come into direct contact with cooling air, and thus are cooled by air at 30°C flowing over the duct with a velocity of 200 m/min. If the surface temperature of the duct is not to exceed 65°C, determine the total power rating of the electronic devices that can be mounted into the duct.

**FIGURE P7–94**

- 7–95** Repeat Prob. 7–94 for a location at 3000-m altitude where the atmospheric pressure is 70.12 kPa.

- 7–96** A 0.2 m × 0.2 m street sign surface has an absorptivity of 0.6 and an emissivity of 0.7, while the street sign is subjected to a cross flow wind at 20°C with a velocity of 1 m/s. Solar radiation is incident on the street sign at a rate

of  $1100 \text{ W/m}^2$ , and the surrounding temperature is  $20^\circ\text{C}$ . Determine the surface temperature of the street sign. Evaluate the air properties at  $30^\circ\text{C}$ . Treat the sign surface as a vertical plate in cross flow.

FIGURE P7-96

**7-97** A coated sheet is being dried with hot air blowing in cross flow on the sheet surface. The surface temperature of the sheet is constant at  $90^\circ\text{C}$ , while the air velocity and temperature are  $0.3 \text{ m/s}$  and  $110^\circ\text{C}$ , respectively. The length of the sheet subjected to the blowing hot air is  $1 \text{ m}$  long. Determine the convection heat transfer coefficient and the heat flux added to the sheet surface. Treat the coated sheet as a vertical plate in cross flow.

FIGURE P7-97

**7-98** Reconsider Prob. 7-97. Using the EES (or other) software, evaluate the hot air velocity on the convection heat transfer coefficient. By varying the hot air velocity from  $0.15$  to  $0.35 \text{ m/s}$ , plot the convection heat transfer coefficient as a function of air velocity.

### Flow across Tube Banks

**7-99C** In flow across tube banks, how does the heat transfer coefficient vary with the row number in the flow direction? How does it vary with in the transverse direction for a given row number?

**7-100C** In flow across tube banks, why is the Reynolds number based on the maximum velocity instead of the uniform approach velocity?

**7-101** A tube bank consists of 300 tubes at a distance of  $6 \text{ cm}$  between the centerlines of any two adjacent tubes. Air approaches the tube bank in the normal direction at  $20^\circ\text{C}$  and  $1 \text{ atm}$  with a mean velocity of  $6 \text{ m/s}$ . There are 20 rows in the flow direction with 15 tubes in each row with an average surface temperature of  $140^\circ\text{C}$ . For an outer tube diameter of  $2 \text{ cm}$ , determine the average heat transfer coefficient. Evaluate the air properties at an assumed mean temperature of  $70^\circ\text{C}$  and  $1 \text{ atm}$ .

**7-102** Water at  $15^\circ\text{C}$  is to be heated to  $65^\circ\text{C}$  by passing it over a bundle of  $4\text{-m-long}$ ,  $1\text{-cm-diameter}$  resistance heater rods maintained at  $90^\circ\text{C}$ . Water approaches the heater rod bundle in normal direction at a mean velocity of  $0.8 \text{ m/s}$ . The rods are arranged in-line with longitudinal and transverse pitches of  $S_L = 4 \text{ cm}$  and  $S_T = 3 \text{ cm}$ . Determine the number of tube rows  $N_L$  in the flow direction needed to achieve the indicated temperature rise.

FIGURE P7-102

**7-103** Air is to be heated by passing it over a bank of  $3\text{-m-long}$  tubes inside which steam is condensing at  $100^\circ\text{C}$ . Air approaches the tube bank in the normal direction at  $20^\circ\text{C}$  and  $1 \text{ atm}$  with a mean velocity of  $5.2 \text{ m/s}$ . The outer diameter of the tubes is  $1.6 \text{ cm}$ , and the tubes are arranged staggered with longitudinal and transverse pitches of  $S_L = S_T = 4 \text{ cm}$ . There are 20 rows in the flow direction with 10 tubes in each row. Determine (a) the rate of heat transfer, (b) and pressure drop across the tube bank, and (c) the rate of condensation of steam inside the tubes. Evaluate the air properties at an assumed mean temperature of  $35^\circ\text{C}$  and  $1 \text{ atm}$ . Is this a good assumption?

**7–104** Repeat Prob. 7–103 for in-line arrangement with  $S_L = S_T = 6$  cm.

**7–105** Exhaust gases at 1 atm and 300°C are used to preheat water in an industrial facility by passing them over a bank of tubes through which water is flowing at a rate of 6 kg/s. The mean tube wall temperature is 80°C. Exhaust gases approach the tube bank in normal direction at 4.5 m/s. The outer diameter of the tubes is 2.1 cm, and the tubes are arranged in-line with longitudinal and transverse pitches of  $S_L = S_T = 8$  cm. There are 16 rows in the flow direction with eight tubes in each row. Using the properties of air for exhaust gases, determine (a) the rate of heat transfer per unit length of tubes, (b) and pressure drop across the tube bank, and (c) the temperature rise of water flowing through the tubes per unit length of tubes. Evaluate the air properties at an assumed mean temperature of 250°C and 1 atm. Is this a good assumption?

**7–106** Air is to be cooled in the evaporator section of a refrigerator by passing it over a bank of 0.8-cm-outer-diameter and 0.4-m-long tubes inside which the refrigerant is evaporating at –20°C. Air approaches the tube bank in the normal direction at 0°C and 1 atm with a mean velocity of 4 m/s. The tubes are arranged in-line with longitudinal and transverse pitches of  $S_L = S_T = 1.5$  cm. There are 30 rows in the flow direction with 15 tubes in each row. Determine (a) the refrigeration capacity of this system and (b) pressure drop across the tube bank. Evaluate the air properties at an assumed mean temperature of –5°C and 1 atm. Is this a good assumption?

FIGURE P7–106

**7–107** Repeat Prob. 7–106 by solving it for staggered arrangement with  $S_L = S_T = 1.5$  cm, and compare the performance of the evaporator for the in-line and staggered arrangements.

**7–108** Combustion air in a manufacturing facility is to be preheated before entering a furnace by hot water at 90°C flowing through the tubes of a tube bank located in a duct. Air enters the duct at 15°C and 1 atm with a mean velocity of 3.8 m/s, and flows over the tubes in normal direction.

The outer diameter of the tubes is 2.1 cm, and the tubes are arranged in-line with longitudinal and transverse pitches of  $S_L = S_T = 5$  cm. There are eight rows in the flow direction with eight tubes in each row. Determine the rate of heat transfer per unit length of the tubes, and the pressure drop across the tube bank. Evaluate the air properties at an assumed mean temperature of 20°C and 1 atm. Is this a good assumption?

**7–109** Repeat Prob. 7–108 for staggered arrangement with  $S_L = S_T = 6$  cm.

### Review Problems

**7–110** Air at 15°C and 1 atm flows over a 0.3-m-wide plate at 65°C at a velocity of 3.0 m/s. Compute the following quantities at  $x = x_{cr}$ :

- (a) Hydrodynamic boundary layer thickness, m
- (b) Local friction coefficient
- (c) Average friction coefficient
- (d) Total drag force due to friction, N
- (e) Local convection heat transfer coefficient, W/m<sup>2</sup>·K
- (f) Average convection heat transfer coefficient, W/m<sup>2</sup>·K
- (g) Rate of convective heat transfer, W

**7–111** Air (1 atm, 5°C) with free stream velocity of 2 m/s flows in parallel to a stationary thin 1 m × 1 m flat plate over the top and bottom surfaces. The flat plate has a uniform surface temperature of 35°C. Determine (a) the average friction coefficient, (b) the average convection heat transfer coefficient, and (c) the average convection heat transfer coefficient using the modified Reynolds analogy and compare with the result obtained in (b).

FIGURE P7–111

**7–112** Four power transistors, each dissipating 12 W, are mounted on a thin vertical aluminum plate ( $k = 237$  W/m·K) 22 cm × 22 cm in size. The heat generated by the transistors is to be dissipated by both surfaces of the plate to the surrounding air at 20°C, which is blown over the plate by a fan at a velocity of 250 m/min. The entire plate can be assumed to be nearly isothermal, and the exposed surface area of the transistor can be taken to be equal to its base area. Determine the temperature of the aluminum plate. Evaluate the air properties at a film temperature of 40°C and 1 atm.

**7–113** Oil at 60°C flows at a velocity of 20 cm/s over a 5.0-m-long and 1.0-m-wide flat plate maintained at a constant temperature of 20°C. Determine the rate of heat transfer

from the oil to the plate if the average oil properties are:  $\rho = 880 \text{ kg/m}^3$ ,  $\mu = 0.005 \text{ kg/m}\cdot\text{s}$ ,  $k = 0.15 \text{ W/m}\cdot\text{K}$ , and  $c_p = 2.0 \text{ kJ/kg}\cdot\text{K}$ .

**7-114E** The passenger compartment of a minivan traveling at 60 mph can be modeled as a 3.2-ft-high, 6-ft-wide, and 11-ft-long rectangular box whose walls have an insulating value of  $R$ -3 (i.e., a wall thickness-to-thermal conductivity ratio of  $3 \text{ h}\cdot\text{ft}^2\cdot^\circ\text{F/Btu}$ ). The interior of a minivan is maintained at an average temperature of  $70^\circ\text{F}$  during a trip at night while the outside air temperature is  $90^\circ\text{F}$ .

The average heat transfer coefficient on the interior surfaces of the van is  $1.2 \text{ Btu/h}\cdot\text{ft}^2\cdot^\circ\text{F}$ . The air flow over the exterior surfaces can be assumed to be turbulent because of the intense vibrations involved, and the heat transfer coefficient on the front and back surfaces can be taken to be equal to that on the top surface. Disregarding any heat gain or loss by radiation, determine the rate of heat transfer from the ambient air to the van. Assume the air flow to be entirely turbulent because of the intense vibrations involved. Use a film temperature of  $80^\circ\text{F}$  for evaluations of air properties at 1 atm.

FIGURE P7-114E

**7-115** A thin, square flat plate has 1.2 m on each side. Air at  $10^\circ\text{C}$  flows over the top and bottom surfaces of a very rough plate in a direction parallel to one edge, with a velocity of 48 m/s. The surface of the plate is maintained at a constant temperature of  $54^\circ\text{C}$ . The plate is mounted on a scale that measures a drag force of 1.5 N. Determine the total heat transfer rate from the plate to the air.

**7-116** Consider a house that is maintained at a constant temperature of  $22^\circ\text{C}$ . One of the walls of the house has three single-pane glass windows that are 1.5 m high and 1.8 m long. The glass ( $k = 0.78 \text{ W/m}\cdot\text{K}$ ) is 0.5 cm thick, and the heat transfer coefficient on the inner surface of the glass is  $8 \text{ W/m}^2\cdot\text{K}$ . Now winds at  $35 \text{ km/h}$  start to blow parallel to the surface of this wall. If the air temperature outside is  $-2^\circ\text{C}$ , determine the rate of heat loss through the windows of this wall. Assume radiation heat transfer to be negligible. Evaluate the air properties at a film temperature of  $5^\circ\text{C}$  and 1 atm.

**7-117** An automotive engine can be approximated as a 0.4-m-high, 0.60-m-wide, and 0.7-m-long rectangular block. The bottom surface of the block is at a temperature of  $75^\circ\text{C}$  and has an emissivity

of 0.92. The ambient air is at  $5^\circ\text{C}$ , and the road surface is at  $10^\circ\text{C}$ . Determine the rate of heat transfer from the bottom surface of the engine block by convection and radiation as the car travels at a velocity of 60 km/h. Assume the flow to be turbulent over the entire surface because of the constant agitation of the engine block. How will the heat transfer be affected when a 2-mm-thick gunk ( $k = 3 \text{ W/m}\cdot\text{K}$ ) has formed at the bottom surface as a result of the dirt and oil collected at that surface over time? Assume the metal temperature under the gunk still to be  $75^\circ\text{C}$ .

FIGURE P7-117

**7-118E** A 15-ft long strip of sheet metal is being transported on a conveyor at a velocity of 16 ft/s. To cure the coating on the upper surface of the sheet metal, infrared lamps providing a constant radiant flux of  $1500 \text{ Btu/h}\cdot\text{ft}^2$  are used. The coating on the upper surface of the metal strip has an absorptivity of 0.6 and an emissivity of 0.7, while the surrounding ambient air temperature is  $77^\circ\text{F}$ . Radiation heat transfer occurs only on the upper surface, while convection heat transfer occurs on both upper and lower surfaces of the sheet metal. Determine the surface temperature of the sheet metal. Evaluate the properties of air at  $180^\circ\text{F}$ .

FIGURE P7-118E

**7-119** To defrost ice accumulated on the outer surface of an automobile windshield, warm air is blown over the inner surface of the windshield. Consider an automobile windshield ( $k_w = 1.4 \text{ W/m}\cdot\text{K}$ ) with an overall height of 0.5 m and thickness of 5 mm. The outside air (1 atm) ambient temperature is  $-20^\circ\text{C}$  and the average airflow velocity over the outer windshield surface is  $80 \text{ km/h}$ , while the ambient temperature inside the automobile is  $25^\circ\text{C}$ . Determine the value of the convection

heat transfer coefficient, for the warm air blowing over the inner surface of the windshield, necessary to cause the accumulated ice to begin melting. Assume the windshield surface can be treated as a flat plate surface.

**FIGURE P7–119**

**7–120** The local atmospheric pressure in Denver, Colorado (elevation 1610 m), is 83.4 kPa. Air at this pressure and  $20^\circ\text{C}$  flows with a velocity of 8 m/s over a  $1.5 \text{ m} \times 6 \text{ m}$  flat plate whose temperature is  $140^\circ\text{C}$ . Determine the rate of heat transfer from the plate if the air flows parallel to the (a) 6-m-long side and (b) the 1.5 m side.

**FIGURE P7–120**

**7–121** A  $20 \text{ mm} \times 20 \text{ mm}$  silicon chip is mounted such that the edges are flush in a substrate. The substrate provides an unheated starting length of 20 mm that acts as turbulator. Air-flow at  $25^\circ\text{C}$  (1 atm) with a velocity of 25 m/s is used to cool the upper surface of the chip. If the maximum surface temperature of the chip cannot exceed  $75^\circ\text{C}$ , determine the maximum allowable power dissipation on the chip surface.

**7–122** Airstream at 1 atm flows, with a velocity of 15 m/s, in parallel over a 3-m-long flat plate where there is an unheated starting length of 1 m. The airstream has a temperature of  $20^\circ\text{C}$  and the heated section of the flat plate is maintained at a constant temperature of  $80^\circ\text{C}$ . Determine (a) the local convection heat transfer coefficient at the trailing edge and (b) the average convection heat transfer coefficient for the heated section.

**7–123** In the effort to increase the removal of heat from a hot surface at  $120^\circ\text{C}$ , a cylindrical pin fin ( $k_f = 237 \text{ W/m}\cdot\text{K}$ ) with diameter of 5 mm is attached to the hot surface. Air at  $20^\circ\text{C}$  (1 atm) is flowing across the pin fin with a velocity of 10 m/s. Determine the maximum possible rate of heat transfer from the pin fin. Evaluate the air properties at  $70^\circ\text{C}$ .

**FIGURE P7–123**

**7–124** Consider a person who is trying to keep cool on a hot summer day by turning a fan on and exposing his body to air flow. The air temperature is  $32^\circ\text{C}$ , and the fan is blowing air at a velocity of 5 m/s. The surrounding surfaces are at  $40^\circ\text{C}$ , and the emissivity of the person can be taken to be 0.9. If the person is doing light work and generating sensible heat at a rate of 90 W, determine the average temperature of the outer surface (skin or clothing) of the person. The average human body can be treated as a 30-cm-diameter cylinder with an exposed surface area of  $1.7 \text{ m}^2$ . Evaluate the air properties at film temperature of  $35^\circ\text{C}$  and 1 atm. *Answer:  $36.2^\circ\text{C}$*

**7–125E** A transistor with a height of 0.25 in and a diameter of 0.22 in is mounted on a circuit board. The transistor is cooled by air flowing over it at a velocity of 500 ft/min. If the air temperature is  $120^\circ\text{F}$  and the transistor case temperature is not to exceed  $180^\circ\text{F}$ , determine the amount of power this transistor can dissipate safely.

**FIGURE P7–125E**

**7–126** Steam at  $250^\circ\text{C}$  flows in a stainless steel pipe ( $k = 15 \text{ W/m}\cdot\text{K}$ ) whose inner and outer diameters are 4 cm

and 4.6 cm, respectively. The pipe is covered with 3.5-cm-thick glass wool insulation ( $k = 0.038 \text{ W/m}\cdot\text{K}$ ) whose outer surface has an emissivity of 0.3. Heat is lost to the surrounding air and surfaces at  $3^\circ\text{C}$  by convection and radiation. Taking the heat transfer coefficient inside the pipe to be  $80 \text{ W/m}^2\cdot\text{K}$ , determine the rate of heat loss from the steam per unit length of the pipe when air is flowing across the pipe at 4 m/s. Evaluate the air properties at a film temperature of  $10^\circ\text{C}$  and 1 atm.

**7-127** A cylindrical rod is placed in a cross flow of air at  $20^\circ\text{C}$  (1 atm) with velocity of 10 m/s. The rod has a diameter of 5 mm and a constant surface temperature of  $120^\circ\text{C}$ . Determine (a) the average drag coefficient, (b) the convection heat transfer coefficient using the Churchill and Bernstein relation, and (c) the convection heat transfer coefficient using Table 7-1.

**7-128** A 3-m-internal-diameter spherical tank made of 1-cm-thick stainless steel ( $k = 15 \text{ W/m}\cdot\text{K}$ ) is used to store iced water at  $0^\circ\text{C}$ . The tank is located outdoors at  $30^\circ\text{C}$  and is subjected to winds at 25 km/h. Assuming the entire steel tank to be at  $0^\circ\text{C}$  and thus its thermal resistance to be negligible, determine (a) the rate of heat transfer to the iced water in the tank and (b) the amount of ice at  $0^\circ\text{C}$  that melts during a 24-h period. The heat of fusion of water at atmospheric pressure is  $h_{if} = 333.7 \text{ kJ/kg}$ . Disregard any heat transfer by radiation.

FIGURE P7-128

**7-129** Repeat Prob. 7-128, assuming the inner surface of the tank to be at  $0^\circ\text{C}$  but by taking the thermal resistance of the tank and heat transfer by radiation into consideration. Assume the average surrounding surface temperature for radiation exchange to be  $25^\circ\text{C}$  and the outer surface of the tank to have an emissivity of 0.75.

Answers: (a)  $10,530 \text{ W}$ , (b)  $2727 \text{ kg}$

**7-130** An array of electrical heating elements is used in an air-duct heater as shown in Fig. P7-130. Each element has a length of 250 mm and a uniform surface temperature of  $350^\circ\text{C}$ . Atmospheric air enters the heater with a velocity of 12 m/s and a temperature of  $25^\circ\text{C}$ . Determine the total heat transfer rate

and the temperature of the air leaving the heater. Neglect the change in air properties as a result of temperature change across the heater. Evaluate the air properties at an assumed mean temperature of  $35^\circ\text{C}$  and 1 atm. Is this a good assumption?

FIGURE P7-130

#### Fundamentals of Engineering (FE) Exam Problems

**7-131** For laminar flow of a fluid along a flat plate, one would expect the largest local convection heat transfer coefficient for the same Reynolds and Prandtl numbers when

- (a) The same temperature is maintained on the surface
- (b) The same heat flux is maintained on the surface
- (c) The plate has an unheated section
- (d) The plate surface is polished
- (e) None of the above

**7-132** Air at  $20^\circ\text{C}$  flows over a 4-m long and 3-m wide surface of a plate whose temperature is  $80^\circ\text{C}$  with a velocity of 5 m/s. The length of the surface for which the flow remains laminar is

- (a) 1.5 m
- (b) 1.8 m
- (c) 2.0 m
- (d) 2.8 m
- (e) 4.0 m

(For air, use  $k = 0.02735 \text{ W/m}\cdot\text{K}$ ,  $\Pr = 0.7228$ ,  $\nu = 1.798 \times 10^{-5} \text{ m}^2/\text{s}$ )

**7-133** Air at  $20^\circ\text{C}$  flows over a 4-m-long and 3-m-wide surface of a plate whose temperature is  $80^\circ\text{C}$  with a velocity of 5 m/s. The rate of heat transfer from the laminar flow region of the surface is

- (a) 950 W
- (b) 1037 W
- (c) 2074 W
- (d) 2640 W
- (e) 3075 W

(For air, use  $k = 0.02735 \text{ W/m}\cdot\text{K}$ ,  $\Pr = 0.7228$ ,  $\nu = 1.798 \times 10^{-5} \text{ m}^2/\text{s}$ )

**7-134** Engine oil at  $105^\circ\text{C}$  flows over the surface of a flat plate whose temperature is  $15^\circ\text{C}$  with a velocity of 1.5 m/s. The local drag force per unit surface area 0.8 m from the leading edge of the plate is

- (a)  $21.8 \text{ N/m}^2$
- (b)  $14.3 \text{ N/m}^2$
- (c)  $10.9 \text{ N/m}^2$
- (d)  $8.5 \text{ N/m}^2$
- (e)  $5.5 \text{ N/m}^2$

(For oil, use  $\nu = 8.565 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\rho = 864 \text{ kg/m}^3$ )

**7–135** Air ( $k = 0.028 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7$ ) at  $50^\circ\text{C}$  flows along a 1-m-long flat plate whose temperature is maintained at  $20^\circ\text{C}$  with a velocity such that the Reynolds number at the end of the plate is 10,000. The heat transfer per unit width between the plate and air is

- (a) 20 W/m    (b) 30 W/m    (c) 40 W/m  
 (d) 50 W/m    (e) 60 W/m

**7–136** Air at  $15^\circ\text{C}$  flows over a flat plate subjected to a uniform heat flux of  $300 \text{ W/m}^2$  with a velocity of 3.5 m/s. The surface temperature of the plate 6 m from the leading edge is

- (a)  $164^\circ\text{C}$     (b)  $68.3^\circ\text{C}$     (c)  $48.1^\circ\text{C}$   
 (d)  $46.8^\circ\text{C}$     (e)  $37.5^\circ\text{C}$

(For air, use  $k = 0.02551 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7296$ ,  $\nu = 1.562 \times 10^{-5} \text{ m}^2/\text{s}$ )

**7–137** Air at  $20^\circ\text{C}$  flows over a 4-m-long and 3-m-wide surface of a plate whose temperature is  $80^\circ\text{C}$  with a velocity of 5 m/s. The rate of heat transfer from the surface is

- (a) 7383 W    (b) 8985 W    (c) 11,231 W  
 (d) 14,672 W    (e) 20,402 W

(For air, use  $k = 0.02735 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7228$ ,  $\nu = 1.798 \times 10^{-5} \text{ m}^2/\text{s}$ )

**7–138** Water at  $75^\circ\text{C}$  flows over a 2-m-long, 2-m-wide surface of a plate whose temperature is  $5^\circ\text{C}$  with a velocity of 1.5 m/s. The total drag force acting on the plate is

- (a) 2.8 N    (b) 12.3 N    (c) 13.7 N  
 (d) 15.4 N    (e) 20.0 N

(For water, use  $\nu = 0.658 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $\rho = 992 \text{ kg/m}^3$ )

**7–139** Air at  $25^\circ\text{C}$  flows over a 5-cm-diameter, 1.7-m-long smooth pipe with a velocity of 4 m/s. A refrigerant at  $-15^\circ\text{C}$  flows inside the pipe and the surface temperature of the pipe is essentially the same as the refrigerant temperature inside. The drag force exerted on the pipe by the air is

- (a) 0.4 N    (b) 1.1 N    (c) 8.5 N  
 (d) 13 N    (e) 18 N

(For air, use  $\nu = 1.382 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\rho = 1.269 \text{ kg/m}^3$ )

**7–140** Air at  $25^\circ\text{C}$  flows over a 5-cm-diameter, 1.7-m-long pipe with a velocity of 4 m/s. A refrigerant at  $-15^\circ\text{C}$  flows inside the pipe and the surface temperature of the pipe is essentially the same as the refrigerant temperature inside. Air properties at the average temperature are  $k = 0.0240 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.735$ ,  $\nu = 1.382 \times 10^{-5} \text{ m}^2/\text{s}$ . The rate of heat transfer to the pipe is

- (a) 343 W    (b) 419 W    (c) 485 W  
 (d) 547 W    (e) 610 W

**7–141** Kitchen water at  $10^\circ\text{C}$  flows over a 10-cm-diameter pipe with a velocity of 1.1 m/s. Geothermal water enters the pipe at  $90^\circ\text{C}$  at a rate of 1.25 kg/s. For calculation purposes, the surface temperature of the pipe may be assumed to be  $70^\circ\text{C}$ . If the geothermal water is to leave the pipe at  $50^\circ\text{C}$ , the required length of the pipe is

- (a) 1.1 m    (b) 1.8 m    (c) 2.9 m  
 (d) 4.3 m    (e) 7.6 m

(For both water streams, use  $k = 0.631 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 4.32$ ,  $\nu = 0.658 \times 10^{-6} \text{ m}^2/\text{s}$ ,  $c_p = 4179 \text{ J/kg}\cdot\text{K}$ )

**7–142** Wind at  $30^\circ\text{C}$  flows over a 0.5-m-diameter spherical tank containing iced water at  $0^\circ\text{C}$  with a velocity of 25 km/h. If the tank is thin-shelled with a high thermal conductivity material, the rate at which ice melts is

- (a) 4.78 kg/h    (b) 6.15 kg/h    (c) 7.45 kg/h  
 (d) 11.8 kg/h    (e) 16.0 kg/h

(Take  $h_f = 333.7 \text{ kJ/kg}$ , and use the following for air:  $k = 0.02588 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7282$ ,  $\nu = 1.608 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\mu_\infty = 1.872 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ ,  $\mu_s = 1.729 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ )

**7–143** Ambient air at  $20^\circ\text{C}$  flows over a 30-cm-diameter hot spherical object with a velocity of 2.5 m/s. If the average surface temperature of the object is  $200^\circ\text{C}$ , the average convection heat transfer coefficient during this process is

- (a) 5.0  $\text{W/m}\cdot\text{K}$     (b) 6.1  $\text{W/m}\cdot\text{K}$   
 (c) 7.5  $\text{W/m}\cdot\text{K}$     (d) 9.3  $\text{W/m}\cdot\text{K}$   
 (e) 11.7  $\text{W/m}\cdot\text{K}$

(For air, use  $k = 0.2514 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 0.7309$ ,  $\nu = 1.516 \times 10^{-5} \text{ m}^2/\text{s}$ ,  $\mu_\infty = 1.825 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ ,  $\mu_s = 2.577 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ )

**7–144** Jakob (1949) suggests the following correlation be used for square tubes in a liquid cross-flow situation:

$$\text{Nu} = 0.102 \text{ Re}^{0.675} \text{ Pr}^{1/3}$$

Water ( $k = 0.61 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 6$ ) at  $50^\circ\text{C}$  flows across a 1-cm square tube with a Reynolds number of 10,000 and surface temperature of  $75^\circ\text{C}$ . If the tube is 2 m long, the rate of heat transfer between the tube and water is

- (a) 6.0 kW    (b) 8.2 kW    (c) 11.3 kW  
 (d) 15.7 kW    (e) 18.1 kW

**7–145** Air ( $\text{Pr} = 0.7$ ,  $k = 0.026 \text{ W/m}\cdot\text{K}$ ) at  $200^\circ\text{C}$  flows across 2-cm-diameter tubes whose surface temperature is  $50^\circ\text{C}$  with a Reynolds number of 8000. The Churchill and Bernstein convective heat transfer correlation for the average Nusselt number in this situation is

$$\text{Nu} = 0.3 + \frac{0.62 \text{ Re}^{0.5} \text{ Pr}^{0.33}}{[1 + (0.4/\text{Pr})^{0.67}]^{0.25}}$$

- (a)  $8.5 \text{ kW/m}^2$     (b)  $9.7 \text{ kW/m}^2$     (c)  $10.5 \text{ kW/m}^2$   
 (d)  $12.2 \text{ kW/m}^2$     (e)  $13.9 \text{ kW/m}^2$

**7–146** Jakob (1949) suggests the following correlation be used for square tubes in a liquid cross-flow situation:

$$\text{Nu} = 0.102 \text{ Re}^{0.625} \text{ Pr}^{1/3}$$

Water ( $k = 0.61 \text{ W/m}\cdot\text{K}$ ,  $\text{Pr} = 6$ ) flows across a 1-cm square tube with a Reynolds number of 10,000. The convection heat transfer coefficient is

- (a)  $5.7 \text{ kW/m}^2\cdot\text{K}$     (b)  $8.3 \text{ kW/m}^2\cdot\text{K}$   
 (c)  $11.2 \text{ kW/m}^2\cdot\text{K}$     (d)  $15.6 \text{ kW/m}^2\cdot\text{K}$   
 (e)  $18.1 \text{ kW/m}^2\cdot\text{K}$

### Design and Essay Problems

**7-147** On average, superinsulated homes use just 15 percent of the fuel required to heat the same size conventional home built before the energy crisis in the 1970s. Write an essay on superinsulated homes, and identify the features that make them so energy efficient as well as the problems associated with them. Do you think superinsulated homes will be economically attractive in your area?

**7-148** Conduct this experiment to determine the heat loss coefficient of your house or apartment in  $\text{W}/\text{C}^\circ$  or  $\text{Btu}/\text{h}\cdot^\circ\text{F}$ . First make sure that the conditions in the house are steady and the house is at the set temperature of the thermostat. Use an outdoor thermometer to monitor outdoor temperature. One evening, using a watch or timer, determine how long the heater was on during a 3-h period and the average outdoor temperature during that period. Then using the heat output rating of your heater, determine the amount of heat supplied. Also, estimate the amount of heat generation in the house during that period by noting the number of people, the total wattage of lights that were on, and the heat generated by the appliances and equipment. Using that information, calculate the average rate of heat loss from the house and the heat loss coefficient.

**7-149** The decision of whether to invest in an energy-saving measure is made on the basis of the length of time for it to pay for itself in projected energy (and thus cost) savings. The easiest way to reach a decision is to calculate the simple payback period by simply dividing the installed cost of the measure by the annual cost savings and comparing it to the lifetime of the installation. This approach is adequate for short payback periods (less than 5 years) in stable economies with low interest rates (under 10 percent) since the error involved is no larger than the uncertainties. However, if the payback period is long, it may be necessary to consider the *interest rate* if the money is to be borrowed, or the *rate of return* if the money is invested elsewhere instead of the energy conservation measure. For example, a simple payback period of five years corresponds to 5.0, 6.12, 6.64, 7.27, 8.09, 9.919, 10.84, and 13.91 for an interest rate (or return on investment) of 0, 6, 8, 10, 12, 14, 16, and 18 percent, respectively. Finding out the proper relations from engineering economics books, determine the payback periods for the interest rates given above corresponding to simple payback periods of 1 through 10 years.

# INTERNAL FORCED CONVECTION

Liquid or gas flow through pipes or ducts is commonly used in heating and cooling applications. The fluid in such applications is forced to flow by a fan or pump through a flow section that is sufficiently long to accomplish the desired heat transfer. In this chapter, we pay particular attention to the determination of the *friction factor* and *convection coefficient* since they are directly related to the *pressure drop* and *heat transfer rate*, respectively. These quantities are then used to determine the pumping power requirement and the required tube length.

There is a fundamental difference between external and internal flows. In *external flow*, considered in Chapter 7, the fluid has a free surface, and thus the boundary layer over the surface is free to grow indefinitely. In *internal flow*, however, the fluid is completely confined by the inner surfaces of the tube, and thus there is a limit on how much the boundary layer can grow.

We start this chapter with a general physical description of internal flow, and the *average velocity* and *average temperature*. We continue with the discussion of the *hydrodynamic* and *thermal entry lengths*, *developing flow*, and *fully developed flow*. We then obtain the velocity and temperature profiles for fully developed laminar flow, and develop relations for the friction factor and Nusselt number. Finally, we present empirical relations for developing and fully developed flows, and demonstrate their use.

## OBJECTIVES

When you finish studying this chapter, you should be able to:

- Obtain average velocity from a knowledge of velocity profile, and average temperature from a knowledge of temperature profile in internal flow,
- Have a visual understanding of different flow regions in internal flow, such as the entry and the fully developed flow regions, and calculate hydrodynamic and thermal entry lengths,
- Analyze heating and cooling of a fluid flowing in a tube under constant surface temperature and constant surface heat flux conditions, and work with the logarithmic mean temperature difference,
- Obtain analytic relations for the velocity profile, pressure drop, friction factor, and Nusselt number in fully developed laminar flow, and
- Determine the friction factor and Nusselt number in fully developed turbulent flow using empirical relations, and calculate the pressure drop and heat transfer rate.

**FIGURE 8-1**

Circular pipes can withstand large pressure differences between the inside and the outside without undergoing any significant distortion, but noncircular pipes cannot.

## 8-1 ■ INTRODUCTION

The terms *pipe*, *duct*, and *conduit* are usually used interchangeably for flow sections. In general, flow sections of circular cross section are referred to as *pipes* (especially when the fluid is a liquid), and flow sections of noncircular cross section as *ducts* (especially when the fluid is a gas). Small-diameter pipes are usually referred to as *tubes*. Given this uncertainty, we will use more descriptive phrases (such as *a circular pipe* or *a rectangular duct*) whenever necessary to avoid any misunderstandings.

You have probably noticed that most fluids, especially liquids, are transported in *circular pipes*. This is because pipes with a circular cross section can withstand large pressure differences between the inside and the outside without undergoing significant distortion. *Noncircular pipes* are usually used in applications such as the heating and cooling systems of buildings where the pressure difference is relatively small, the manufacturing and installation costs are lower, and the available space is limited for ductwork (Fig. 8-1). For a fixed surface area, the circular tube gives the most heat transfer for the least pressure drop, which explains the overwhelming popularity of circular tubes in heat transfer equipment.

Although the theory of fluid flow is reasonably well understood, theoretical solutions are obtained only for a few simple cases such as fully developed laminar flow in a circular pipe. Therefore, we must rely on experimental results and empirical relations for most fluid flow problems rather than closed-form analytical solutions. Noting that the experimental results are obtained under carefully controlled laboratory conditions and that no two systems are exactly alike, we must not be so naive as to view the results obtained as "exact." An error of 10 percent (or more) in friction factors calculated using the relations in this chapter is the "norm" rather than the "exception."

The fluid velocity in a pipe changes from *zero* at the wall because of the no-slip condition to a maximum at the pipe center. In fluid flow, it is convenient to work with an *average* velocity  $V_{\text{avg}}$ , which remains constant in incompressible flow when the cross-sectional area of the pipe is constant (Fig. 8-2). The average velocity in heating and cooling applications may change somewhat because of changes in density with temperature. But, in practice, we evaluate the fluid properties at some average temperature and treat them as constants. The convenience of working with constant properties usually more than justifies the slight loss in accuracy.

Also, the friction between the fluid particles in a pipe does cause a slight rise in fluid temperature as a result of the mechanical energy being converted to sensible thermal energy. But this temperature rise due to *frictional heating* is usually too small to warrant any consideration in calculations and thus is disregarded. For example, in the absence of any heat transfer, no noticeable difference can be detected between the inlet and outlet temperatures of water flowing in a pipe. The primary consequence of friction in fluid flow is pressure drop, and thus any significant temperature change in the fluid is due to heat transfer. But frictional heating must be considered for flows that involve highly viscous fluids with large velocity gradients.

**FIGURE 8-2**

Average velocity  $V_{\text{avg}}$  is defined as the average speed through a cross section. For fully developed laminar pipe flow,  $V_{\text{avg}}$  is half of the maximum velocity.

## 8–2 ■ AVERAGE VELOCITY AND TEMPERATURE

In external flow, the free-stream velocity served as a convenient reference velocity for use in the evaluation of the Reynolds number and the friction coefficient. In internal flow, there is no free stream and thus we need an alternative. The fluid velocity in a tube changes from zero at the surface because of the no-slip condition, to a maximum at the tube center. Therefore, it is convenient to work with an **average or mean velocity**  $V_{\text{avg}}$ , which remains constant for incompressible flow when the cross sectional area of the tube is constant.

The value of the average velocity  $V_{\text{avg}}$  at some streamwise cross section is determined from the requirement that the *conservation of mass* principle be satisfied (Fig. 8–2). That is,

$$\dot{m} = \rho V_{\text{avg}} A_c = \int_{A_c} \rho u(r) dA_c \quad (8-1)$$

where  $\dot{m}$  is the mass flow rate,  $\rho$  is the density,  $A_c$  is the cross-sectional area, and  $u(r)$  is the velocity profile. Then, the average velocity for incompressible flow in a circular pipe of radius  $R$  is expressed as

$$V_{\text{avg}} = \frac{\int_{A_c} \rho u(r) dA_c}{\rho A_c} = \frac{\int_0^R \rho u(r) 2\pi r dr}{\rho \pi R^2} = \frac{2}{R^2} \int_0^R u(r) r dr \quad (8-2)$$

Therefore, when we know the flow rate or the velocity profile, the average velocity can be determined easily.

When a fluid is heated or cooled as it flows through a tube, the temperature of the fluid at any cross section changes from  $T_s$  at the surface of the wall to some maximum (or minimum in the case of heating) at the tube center. In fluid flow, it is convenient to work with an **average or mean temperature**  $T_m$ , which remains constant at a cross section. Unlike the mean velocity, the mean temperature  $T_m$  changes in the flow direction whenever the fluid is heated or cooled.

The value of the mean temperature  $T_m$  is determined from the requirement that the *conservation of energy* principle be satisfied. That is, the energy transported by the fluid through a cross section in actual flow must be equal to the energy that would be transported through the same cross section if the fluid were at a constant temperature  $T_m$ . This can be expressed mathematically as (Fig. 8–3)

$$\dot{E}_{\text{fluid}} = \dot{m} c_p T_m = \int_{A_c} c_p T(r) \delta m = \int_{A_c} \rho c_p T(r) u(r) dA_c \quad (8-3)$$

where  $c_p$  is the specific heat of the fluid. Note that the product  $\dot{m} c_p T_m$  at any cross section along the tube represents the *energy flow* with the fluid at that cross section. Then, the mean temperature of a fluid with constant density and specific heat flowing in a circular pipe of radius  $R$  can be expressed as

$$T_m = \frac{\int_{A_c} c_p T(r) \delta m}{\dot{m} c_p} = \frac{\int_0^R c_p T(r) \rho u(r) 2\pi r dr}{\rho V_{\text{avg}} (\pi R^2) c_p} = \frac{2}{V_{\text{avg}} R^2} \int_0^R T(r) u(r) r dr \quad (8-4)$$

Note that the mean temperature  $T_m$  of a fluid changes during heating or cooling. Also, the fluid properties in internal flow are usually evaluated at the *bulk*

**FIGURE 8–3**

Actual and idealized temperature profiles for flow in a tube (the rate at which energy is transported with the fluid is the same for both cases).

**FIGURE 8-4**

The hydraulic diameter  $D_h = 4A_c/p$  is defined such that it reduces to ordinary diameter for circular tubes. When there is a free surface, such as in open-channel flow, the wetted perimeter includes only the walls in contact with the fluid.

mean fluid temperature, which is the arithmetic average of the mean temperatures at the inlet and the exit. That is,  $T_b = (T_i + T_e)/2$ .

## Laminar and Turbulent Flow in Tubes

Flow in a tube can be laminar or turbulent, depending on the flow conditions. Fluid flow is streamlined and thus laminar at low velocities, but turns turbulent as the velocity is increased beyond a critical value. Transition from laminar to turbulent flow does not occur suddenly; rather, it occurs over some range of velocity where the flow fluctuates between laminar and turbulent flows before it becomes fully turbulent. Most pipe flows encountered in practice are turbulent. Laminar flow is encountered when highly viscous fluids such as oils flow in small diameter tubes or narrow passages.

For flow in a circular tube, the Reynolds number is defined as

$$Re = \frac{V_{avg}D}{\nu} = \frac{\rho V_{avg}D}{\mu} = \frac{\rho D}{\mu} \left( \frac{\dot{m}}{\rho \pi D^2/4} \right) = \frac{4\dot{m}}{\mu \pi D} \quad (8-5)$$

where  $V_{avg}$  is the average flow velocity,  $D$  is the diameter of the tube, and  $\nu = \mu/\rho$  is the kinematic viscosity of the fluid.

For flow through noncircular tubes, the Reynolds number as well as the Nusselt number, and the friction factor are based on the **hydraulic diameter**  $D_h$  defined as (Fig. 8-4)

$$D_h = \frac{4A_c}{p} \quad (8-6)$$

where  $A_c$  is the cross sectional area of the tube and  $p$  is its wetted perimeter. The hydraulic diameter is defined such that it reduces to ordinary diameter  $D$  for circular tubes since

$$\text{Circular tubes: } D_h = \frac{4A_c}{p} = \frac{4\pi D^2/4}{\pi D} = D$$

It certainly is desirable to have precise values of Reynolds numbers for laminar, transitional, and turbulent flows, but this is not the case in practice. This is because the transition from laminar to turbulent flow also depends on the degree of disturbance of the flow by *surface roughness*, *pipe vibrations*, and the *fluctuations in the flow*. Under most practical conditions, the flow in a tube is laminar for  $Re < 2300$ , fully turbulent for  $Re > 10,000$ , and transitional in between. But it should be kept in mind that in many cases the flow becomes fully turbulent for  $Re > 4000$ , as discussed in the Topic of Special Interest later in this chapter. When designing piping networks and determining pumping power, a conservative approach is taken and flows with  $Re > 4000$  are assumed to be turbulent.

In transitional flow, the flow switches between laminar and turbulent in a disorderly fashion (Fig. 8-5). It should be kept in mind that laminar flow can be maintained at much higher Reynolds numbers in very smooth pipes by avoiding flow disturbances and tube vibrations. In such carefully controlled experiments, laminar flow has been maintained at Reynolds numbers of up to 100,000.

**FIGURE 8-5**

In the transitional flow region of the flow switches between laminar and turbulent somewhat randomly.

## 8–3 ■ THE ENTRANCE REGION

Consider a fluid entering a circular pipe at a uniform velocity. Because of the no-slip condition, the fluid particles in the layer in contact with the wall of the pipe come to a complete stop. This layer also causes the fluid particles in the adjacent layers to slow down gradually as a result of friction. To make up for this velocity reduction, the velocity of the fluid at the midsection of the pipe has to increase to keep the mass flow rate through the pipe constant. As a result, a velocity gradient develops along the pipe.

The region of the flow in which the effects of the viscous shearing forces caused by fluid viscosity are felt is called the **velocity boundary layer** or just the **boundary layer**. The hypothetical boundary surface divides the flow in a pipe into two regions: the **boundary layer region**, in which the viscous effects and the velocity changes are significant, and the **irrotational (core) flow region**, in which the frictional effects are negligible and the velocity remains essentially constant in the radial direction.

The thickness of this boundary layer increases in the flow direction until the boundary layer reaches the pipe center and thus fills the entire pipe, as shown in Fig. 8–6, and the velocity becomes fully developed a little further downstream. The region from the pipe inlet to the point at which the velocity profile is fully developed is called the **hydrodynamic entrance region**, and the length of this region is called the **hydrodynamic entry length**  $L_h$ . Flow in the entrance region is called *hydrodynamically developing flow* since this is the region where the velocity profile develops. The region beyond the entrance region in which the velocity profile is fully developed and remains unchanged is called the **hydrodynamically fully developed region**. The velocity profile in the fully developed region is *parabolic* in laminar flow and somewhat *flatter* or *fuller* in turbulent flow due to eddy motion and more vigorous mixing in radial direction.

Now consider a fluid at a uniform temperature entering a circular tube whose surface is maintained at a different temperature. This time, the fluid particles in the layer in contact with the surface of the tube assume the surface temperature. This initiates convection heat transfer in the tube and the development of a *thermal boundary layer* along the tube. The thickness of this boundary layer also increases in the flow direction until the boundary layer reaches the tube center and thus fills the entire tube, as shown in Fig. 8–7.

**FIGURE 8–6**

The development of the velocity boundary layer in a pipe. (The developed average velocity profile is parabolic in laminar flow, as shown, but much flatter or fuller in turbulent flow.)

**FIGURE 8-7**

The development of the thermal boundary layer in a tube. (The fluid in the tube is being cooled.)

The region of flow over which the thermal boundary layer develops and reaches the tube center is called the **thermal entrance region**, and the length of this region is called the **thermal entry length**  $L_t$ . Flow in the thermal entrance region is called *thermally developing flow* since this is the region where the temperature profile develops. The region beyond the thermal entrance region in which the dimensionless temperature profile expressed as  $(T_s - T)/(T_s - T_m)$  remains unchanged is called the **thermally fully developed region**. The region in which the flow is both hydrodynamically and thermally developed and thus both the velocity and dimensionless temperature profiles remain unchanged is called **fully developed flow**. That is,

$$\text{Hydrodynamically fully developed: } \frac{\partial u(r, x)}{\partial x} = 0 \longrightarrow u = u(r) \quad (8-7)$$

$$\text{Thermally fully developed: } \frac{\partial}{\partial x} \left[ \frac{T_s(x) - T(r, x)}{T_s(x) - T_m(x)} \right] = 0 \quad (8-8)$$

The shear stress at the tube wall  $\tau_w$  is related to the slope of the velocity profile at the surface. Noting that the velocity profile remains unchanged in the hydrodynamically fully developed region, the wall shear stress also remains constant in that region. A similar argument can be given for the heat transfer coefficient in the thermally fully developed region.

In a thermally fully developed region, the derivative of  $(T_s - T)/(T_s - T_m)$  with respect to  $x$  is zero by definition, and thus  $(T_s - T)/(T_s - T_m)$  is independent of  $x$ . Then, the derivative of  $(T_s - T)/(T_s - T_m)$  with respect to  $r$  must also be independent of  $x$ . That is,

$$\frac{\partial}{\partial r} \left( \frac{T_s - T}{T_s - T_m} \right) \Big|_{r=R} = - \frac{(\partial T / \partial r)|_{r=R}}{T_s - T_m} \neq f(x) \quad (8-9)$$

Surface heat flux can be expressed as

$$\dot{q}_s = h_x(T_s - T_m) = k \frac{\partial T}{\partial r} \Big|_{r=R} \longrightarrow h_x = \frac{k(\partial T / \partial r)|_{r=R}}{T_s - T_m} \quad (8-10)$$

which, from Eq. 8-9, is independent of  $x$ . Thus, we conclude that *in the thermally fully developed region of a tube, the local convection coefficient is constant* (does not vary with  $x$ ). Therefore, both the local friction factor  $f_x$  (which is related to the local wall shear stress) and the local convection coefficient  $h_x$  remain constant in the hydrodynamically and thermally fully developed regions, respectively, as shown in Fig. 8-8 for  $\text{Pr} > 1$ .

**FIGURE 8-8**

Variation of the friction factor and the convection heat transfer coefficient in the flow direction for flow in a tube ( $\text{Pr} > 1$ ).

Note that the *temperature profile* in the thermally fully developed region may vary with  $x$  in the flow direction. That is, unlike the velocity profile, the temperature profile can be different at different cross sections of the tube in the developed region, and it usually is. However, the dimensionless temperature profile defined previously remains unchanged in the thermally developed region when the temperature or heat flux at the tube surface remains constant.

During laminar flow in a tube, the magnitude of the dimensionless Prandtl number  $\text{Pr}$  is a measure of the relative growth of the velocity and thermal boundary layers. For fluids with  $\text{Pr} \approx 1$ , such as gases, the two boundary layers essentially coincide with each other. For fluids with  $\text{Pr} \gg 1$ , such as oils, the velocity boundary layer outgrows the thermal boundary layer. As a result, the hydrodynamic entry length is smaller than the thermal entry length. The opposite is true for fluids with  $\text{Pr} \ll 1$  such as liquid metals.

Consider a fluid that is being heated (or cooled) in a tube as it flows through it. The wall shear stress and the heat transfer coefficient are *highest* at the tube inlet where the thickness of the boundary layers is smallest, and decrease gradually to the fully developed values, as shown in Fig. 8–8. Therefore, the pressure drop and heat flux are *higher* in the entrance regions of a tube, and the effect of the entrance region is always to *increase* the average friction factor and heat transfer coefficient for the entire tube. This enhancement can be significant for short tubes but negligible for long ones.

## Entry Lengths

The hydrodynamic entry length is usually taken to be the distance from the tube entrance where the wall shear stress (and thus the friction factor) reaches within about 2 percent of the fully developed value. In *laminar flow*, the hydrodynamic and thermal entry lengths are given approximately as [see Kays and Crawford (1993) and Shah and Bhatti (1987)]

$$L_{h, \text{laminar}} \approx 0.05 \text{ Re } D \quad (8-11)$$

$$L_{t, \text{laminar}} \approx 0.05 \text{ Re } \text{Pr } D = \text{Pr } L_{h, \text{laminar}} \quad (8-12)$$

For  $\text{Re} = 20$ , the hydrodynamic entry length is about the size of the diameter, but increases linearly with velocity. In the limiting case of  $\text{Re} = 2300$ , the hydrodynamic entry length is  $115D$ .

In *turbulent flow*, the intense mixing during random fluctuations usually overshadows the effects of molecular diffusion, and therefore the hydrodynamic and thermal entry lengths are of about the same size and independent of the Prandtl number.

The entry length is much shorter in turbulent flow, as expected, and its dependence on the Reynolds number is weaker. In many tube flows of practical interest, the entrance effects become insignificant beyond a tube length of 10 diameters, and the hydrodynamic and thermal entry lengths are approximately taken to be

$$L_{h, \text{turbulent}} \approx L_{t, \text{turbulent}} \approx 10D \quad (8-13)$$

The variation of local Nusselt number along a tube in turbulent flow for both constant surface temperature and constant surface heat flux is given

**FIGURE 8-9**

Variation of local Nusselt number along a tube in turbulent flow for both constant surface temperature and constant surface heat flux [Deissler (1953)].

in Fig. 8-9 for the range of Reynolds numbers encountered in heat transfer equipment. We make these important observations from this figure:

- The Nusselt numbers and thus the convection heat transfer coefficients are much higher in the entrance region.
- The Nusselt number reaches a constant value at a distance of less than 10 diameters, and thus the flow can be assumed to be fully developed for  $x > 10D$ .
- The Nusselt numbers for the constant surface temperature and constant surface heat flux conditions are identical in the fully developed regions, and nearly identical in the entrance regions. Therefore, Nusselt number is insensitive to the type of thermal boundary condition, and the turbulent flow correlations can be used for either type of boundary condition.

Precise correlations for the friction and heat transfer coefficients for the entrance regions are available in the literature. However, the tubes used in practice in forced convection are usually several times the length of either entrance region, and thus the flow through the tubes is often assumed to be fully developed for the entire length of the tube. This simplistic approach gives *reasonable* results for the rate of heat transfer for long tubes and *conservative* results for short ones.

It should be noted that the above observations are only valid for turbulent flow. In laminar flow Nusselt number values are much lower than turbulent flow values, the distance for the Nusselt number to reach a constant value is typically much longer, and the flow is sensitive to the thermal boundary conditions imposed on the flow.

**FIGURE 8-10**

The heat transfer to a fluid flowing in a tube is equal to the increase in the energy of the fluid.

## 8-4 ■ GENERAL THERMAL ANALYSIS

In the absence of any work interactions (such as electric resistance heating), the conservation of energy equation for the steady flow of a fluid in a tube can be expressed as (Fig. 8-10)

$$\dot{Q} = \dot{m}c_p(T_e - T_i) \quad (\text{W}) \quad (8-14)$$

where  $T_i$  and  $T_e$  are the mean fluid temperatures at the inlet and exit of the tube, respectively, and  $\dot{Q}$  is the rate of heat transfer to or from the fluid. Note that the temperature of a fluid flowing in a tube remains constant in the absence of any energy interactions through the wall of the tube.

The thermal conditions at the surface can usually be approximated with reasonable accuracy to be *constant surface temperature* ( $T_s = \text{constant}$ ) or *constant surface heat flux* ( $\dot{q}_s = \text{constant}$ ). For example, the constant surface temperature condition is realized when a phase change process such as boiling or condensation occurs at the outer surface of a tube. The constant surface heat flux condition is realized when the tube is subjected to radiation or electric resistance heating uniformly from all directions.

Surface heat flux is expressed as

$$\dot{q}_s = h_x(T_s - T_m) \quad (\text{W/m}^2) \quad (8-15)$$

where  $h_x$  is the *local* heat transfer coefficient and  $T_s$  and  $T_m$  are the surface and the mean fluid temperatures at that location. Note that the mean fluid temperature  $T_m$  of a fluid flowing in a tube must change during heating or cooling. Therefore, when  $h_x = h = \text{constant}$ , the surface temperature  $T_s$  must change when  $\dot{q}_s = \text{constant}$ , and the surface heat flux  $\dot{q}_s$  must change when  $T_s = \text{constant}$ . Thus we may have either  $T_s = \text{constant}$  or  $\dot{q}_s = \text{constant}$  at the surface of a tube, but not both. Next we consider convection heat transfer for these two common cases.

## Constant Surface Heat Flux ( $\dot{q}_s = \text{constant}$ )

In the case of  $\dot{q}_s = \text{constant}$ , the rate of heat transfer can also be expressed as

$$\dot{Q} = \dot{q}_s A_s = \dot{m} c_p (T_e - T_i) \quad (\text{W}) \quad (8-16)$$

Then the mean fluid temperature at the tube exit becomes

$$T_e = T_i + \frac{\dot{q}_s A_s}{\dot{m} c_p} \quad (8-17)$$

Note that the mean fluid temperature increases *linearly* in the flow direction in the case of constant surface heat flux, since the surface area increases linearly in the flow direction ( $A_s$  is equal to the perimeter, which is constant, times the tube length).

The surface temperature in the case of constant surface heat flux  $\dot{q}_s$  can be determined from

$$\dot{q}_s = h(T_s - T_m) \longrightarrow T_s = T_m + \frac{\dot{q}_s}{h} \quad (8-18)$$

In the fully developed region, the surface temperature  $T_s$  will also increase linearly in the flow direction since  $h$  is constant and thus  $T_s - T_m = \text{constant}$  (Fig. 8-11). Of course this is true when the fluid properties remain constant during flow.

The slope of the mean fluid temperature  $T_m$  on a  $T$ - $x$  diagram can be determined by applying the steady-flow energy balance to a tube slice of thickness  $dx$  shown in Fig. 8-12. It gives

$$\dot{m} c_p dT_m = \dot{q}_s (pdx) \longrightarrow \frac{dT_m}{dx} = \frac{\dot{q}_s p}{\dot{m} c_p} = \text{constant} \quad (8-19)$$

where  $p$  is the perimeter of the tube.

**FIGURE 8-11**

Variation of the *tube surface* and the *mean fluid* temperatures along the tube for the case of constant surface heat flux.

**FIGURE 8-12**

Energy interactions for a differential control volume in a tube.

Noting that both  $\dot{q}_s$  and  $h$  are constants, the differentiation of Eq. 8–18 with respect to  $x$  gives

$$\frac{dT_m}{dx} = \frac{dT_s}{dx} \quad (8-20)$$

Also, the requirement that the dimensionless temperature profile remains unchanged in the fully developed region gives

$$\frac{\partial}{\partial x} \left( \frac{T_s - T}{T_s - T_m} \right) = 0 \longrightarrow \frac{1}{T_s - T_m} \left( \frac{\partial T_s}{\partial x} - \frac{\partial T}{\partial x} \right) = 0 \longrightarrow \frac{\partial T}{\partial x} = \frac{dT_s}{dx} \quad (8-21)$$

since  $T_s - T_m = \text{constant}$ . Combining Eqs. 8–19, 8–20, and 8–21 gives

$$\frac{\partial T}{\partial x} = \frac{dT_s}{dx} = \frac{dT_m}{dx} = \frac{\dot{q}_s p}{mc_p} = \text{constant} \quad (8-22)$$

Then we conclude that *in fully developed flow in a tube subjected to constant surface heat flux, the temperature gradient is independent of  $x$  and thus the shape of the temperature profile does not change along the tube* (Fig. 8–13).

Integrating Eq. 8–22 from  $x = 0$  (tube inlet where  $T_m = T_i$ ) we obtain an expression for the variation of mean temperature along the tube

$$T_m = T_i + \frac{\dot{q}_s p}{mc_p} x \quad (8-23)$$

Evaluating the above equation at  $x = L$  (tube exit where  $T_m = T_e$ ). Then recognizing that  $A_s = pL$ , Eq. 8–17 is obtained. From the above equation we can conclude again that the mean temperature varies linearly with  $x$  along the tube for the case of constant heat flux.

For a circular tube,  $p = 2\pi R$  and  $\dot{m} = \rho V_{\text{avg}} A_c = \rho V_{\text{avg}} (\pi R^2)$ . Then Eq. 8–22 becomes

$$\text{Circular tube: } \frac{\partial T}{\partial x} = \frac{dT_s}{dx} = \frac{dT_m}{dx} = \frac{2\dot{q}_s}{\rho V_{\text{avg}} c_p R} = \text{constant} \quad (8-24)$$

where  $V_{\text{avg}}$  is the mean velocity of the fluid.

## Constant Surface Temperature ( $T_s = \text{constant}$ )

From Newton's law of cooling, the rate of heat transfer to or from a fluid flowing in a tube can be expressed as

$$\dot{Q} = hA_s \Delta T_{\text{avg}} = hA_s(T_s - T_m)_{\text{avg}} \quad (\text{W}) \quad (8-25)$$

where  $h$  is the average convection heat transfer coefficient,  $A_s$  is the heat transfer surface area (it is equal to  $\pi DL$  for a circular pipe of length  $L$ ), and  $\Delta T_{\text{avg}}$  is some appropriate *average* temperature difference between the fluid and the surface. Below we discuss two suitable ways of expressing  $\Delta T_{\text{avg}}$ .

In the constant surface temperature ( $T_s = \text{constant}$ ) case,  $\Delta T_{\text{avg}}$  can be expressed *approximately* by the **arithmetic mean temperature difference**  $\Delta T_{\text{am}}$  as

$$\Delta T_{\text{avg}} \approx \Delta T_{\text{am}} = \frac{\Delta T_i + \Delta T_e}{2} = \frac{(T_s - T_i) + (T_s - T_e)}{2} = T_s - \frac{T_i + T_e}{2} = T_s - T_b \quad (8-26)$$

where  $T_b = (T_i + T_e)/2$  is the *bulk mean fluid temperature*, which is the *arithmetic average* of the mean fluid temperatures at the inlet and the exit of the tube.

**FIGURE 8–13**

The shape of the temperature profile remains unchanged in the fully developed region of a tube subjected to constant surface heat flux.

Note that the *arithmetic mean temperature difference*  $\Delta T_{\text{avg}}$  is simply the *average* of the *temperature differences* between the surface and the fluid at the inlet and the exit of the tube. Inherent in this definition is the assumption that the mean fluid temperature varies linearly along the tube, which is hardly ever the case when  $T_s = \text{constant}$ . This simple approximation often gives acceptable results, but not always. Therefore, we need a better way to evaluate  $\Delta T_{\text{avg}}$ .

Consider the heating of a fluid in a tube of constant cross section whose inner surface is maintained at a constant temperature of  $T_s$ . We know that the mean temperature of the fluid  $T_m$  increases in the flow direction as a result of heat transfer. The energy balance on a differential control volume shown in Fig. 8–12 gives

$$\dot{m} c_p dT_m = h(T_s - T_m) dA_s \quad (8-27)$$

That is, the increase in the energy of the fluid (represented by an increase in its mean temperature by  $dT_m$ ) is equal to the heat transferred to the fluid from the tube surface by convection. Noting that the differential surface area is  $dA_s = pdx$ , where  $p$  is the perimeter of the tube, and that  $dT_m = -d(T_s - T_m)$ , since  $T_s$  is constant, the relation above can be rearranged as

$$\frac{d(T_s - T_m)}{T_s - T_m} = -\frac{hp}{\dot{m}c_p} dx \quad (8-28)$$

Integrating from  $x = 0$  (tube inlet where  $T_m = T_i$ ) to  $x = L$  (tube exit where  $T_m = T_e$ ) gives

$$\ln \frac{T_s - T_e}{T_s - T_i} = -\frac{hA_s}{\dot{m}c_p} \quad (8-29)$$

where  $A_s = pL$  is the surface area of the tube and  $h$  is the constant *average* convection heat transfer coefficient. Taking the exponential of both sides and solving for  $T_e$  gives the following relation which is very useful for the determination of the *mean fluid temperature at the tube exit*:

$$T_e = T_s - (T_s - T_i) \exp(-hA_s/\dot{m}c_p) \quad (8-30)$$

This relation can also be used to determine the mean fluid temperature  $T_m(x)$  at any  $x$  by replacing  $A_s = pL$  by  $px$ .

Note that the temperature difference between the fluid and the surface *decays exponentially* in the flow direction, and the rate of decay depends on the magnitude of the exponent  $hA_s/\dot{m}c_p$ , as shown in Fig. 8–14. This dimensionless parameter is called the *number of transfer units*, denoted by NTU, and is a measure of the effectiveness of the heat transfer systems. For  $\text{NTU} > 5$ , the exit temperature of the fluid becomes almost equal to the surface temperature,  $T_e \approx T_s$  (Fig. 8–15). Noting that the fluid temperature can approach the surface temperature but cannot cross it, an NTU of about 5 indicates that the limit is reached for heat transfer, and the heat transfer does not increase no matter how much we extend the length of the tube. A small value of NTU, on the other hand, indicates more opportunities for heat transfer, and the heat transfer continues to increase as the tube length is increased. A large NTU and thus a large heat transfer surface area (which means a large tube) may be desirable from a heat transfer point of view, but it may be unacceptable from an economic point of view. The selection of heat transfer equipment usually reflects a compromise between heat transfer performance and cost.

**FIGURE 8-14**

The variation of the *mean fluid temperature* along the tube for the case of constant temperature.

**FIGURE 8-15**

An NTU greater than 5 indicates that the fluid flowing in a tube will reach the surface temperature at the exit regardless of the inlet temperature.

Solving Eq. 8–29 for  $\dot{m}c_p$  gives

$$\dot{m}c_p = -\frac{hA_s}{\ln[(T_s - T_e)/(T_s - T_i)]} \quad (8-31)$$

Substituting this into Eq. 8–14, we obtain

$$\dot{Q} = hA_s \Delta T_{lm} \quad (8-32)$$

where

$$\Delta T_{lm} = \frac{T_i - T_e}{\ln[(T_s - T_e)/(T_s - T_i)]} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e/\Delta T_i)} \quad (8-33)$$

is the **log mean temperature difference**. Note that  $\Delta T_i = T_s - T_i$  and  $\Delta T_e = T_s - T_e$  are the temperature differences between the surface and the fluid at the inlet and the exit of the tube, respectively. This  $\Delta T_{lm}$  relation appears to be prone to misuse, but it is practically fail-safe, since using  $T_i$  in place of  $T_e$  and vice versa in the numerator and/or the denominator will, at most, affect the sign, not the magnitude. Also, it can be used for both heating ( $T_s > T_i$  and  $T_e$ ) and cooling ( $T_s < T_i$  and  $T_e$ ) of a fluid in a tube.

The log mean temperature difference  $\Delta T_{lm}$  is obtained by tracing the actual temperature profile of the fluid along the tube, and is an *exact* representation of the *average temperature difference* between the fluid and the surface. It truly reflects the exponential decay of the local temperature difference. When  $\Delta T_e$  differs from  $\Delta T_i$  by no more than 40 percent, the error in using the arithmetic mean temperature difference is less than 1 percent. But the error increases to undesirable levels when  $\Delta T_e$  differs from  $\Delta T_i$  by greater amounts. Therefore, we should always use the log mean temperature difference when determining the convection heat transfer in a tube whose surface is maintained at a constant temperature  $T_s$ .

**FIGURE 8–16**  
Schematic for Example 8–1.

### EXAMPLE 8–1 Heating of Water in a Tube by Steam

Water enters a 2.5-cm-internal-diameter thin copper tube of a heat exchanger at 15°C at a rate of 0.3 kg/s, and is heated by steam condensing outside at 120°C. If the average heat transfer coefficient is 800 W/m<sup>2</sup>·K, determine the length of the tube required in order to heat the water to 115°C (Fig. 8–16).

**SOLUTION** Water is heated by steam in a circular tube. The tube length required to heat the water to a specified temperature is to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Fluid properties are constant. 3 The convection heat transfer coefficient is constant. 4 The conduction resistance of copper tube is negligible so that the inner surface temperature of the tube is equal to the condensation temperature of steam.

**Properties** The specific heat of water at the bulk mean temperature of  $(15 + 115)/2 = 65^\circ\text{C}$  is 4187 J/kg·K. The heat of condensation of steam at 120°C is 2203 kJ/kg (Table A–9).

**Analysis** Knowing the inlet and exit temperatures of water, the rate of heat transfer is determined to be

$$\begin{aligned} \dot{Q} &= \dot{m}c_p(T_e - T_i) = (0.3 \text{ kg/s})(4.187 \text{ kJ/kg}\cdot\text{K})(115^\circ\text{C} - 15^\circ\text{C}) \\ &= 125.6 \text{ kW} \end{aligned}$$

The log mean temperature difference is

$$\Delta T_e = T_s - T_e = 120^\circ\text{C} - 115^\circ\text{C} = 5^\circ\text{C}$$

$$\Delta T_i = T_s - T_i = 120^\circ\text{C} - 15^\circ\text{C} = 105^\circ\text{C}$$

$$\Delta T_{lm} = \frac{\Delta T_e - \Delta T_i}{\ln(\Delta T_e/\Delta T_i)} = \frac{5 - 105}{\ln(5/105)} = 32.85^\circ\text{C}$$

The heat transfer surface area is

$$\dot{Q} = hA_s\Delta T_{lm} \longrightarrow A_s = \frac{\dot{Q}}{h\Delta T_{lm}} = \frac{125.6 \text{ kW}}{(0.8 \text{ kW/m}^2\cdot\text{K})(32.85^\circ\text{C})} = 4.78 \text{ m}^2$$

Then the required tube length becomes

$$A_s = \pi DL \longrightarrow L = \frac{A_s}{\pi D} = \frac{4.78 \text{ m}^2}{\pi(0.025 \text{ m})} = 61 \text{ m}$$

**Discussion** The bulk mean temperature of water during this heating process is  $65^\circ\text{C}$ , and thus the *arithmetic* mean temperature difference is  $\Delta T_{am} = 120 - 65 = 55^\circ\text{C}$ . Using  $\Delta T_{am}$  instead of  $\Delta T_{lm}$  would give  $L = 36 \text{ m}$ , which is grossly in error. This shows the importance of using the log mean temperature in calculations.

## 8–5 • LAMINAR FLOW IN TUBES

We mentioned in Section 8–2 that flow in tubes is laminar for  $\text{Re} \leq 2300$ , and that the flow is fully developed if the tube is sufficiently long (relative to the entry length) so that the entrance effects are negligible. In this section we consider steady, laminar, incompressible flow of a fluid with constant properties in the fully developed region of a straight circular pipe. We obtain the momentum equation by applying a force balance to a differential volume element, and obtain the velocity profile by solving it. Then we use it to obtain a relation for the friction factor. An important aspect of the analysis here is that it is one of the few available for viscous flow.

In fully developed laminar flow, each fluid particle moves at a constant axial velocity along a streamline and the velocity profile  $u(r)$  remains unchanged in the flow direction. There is no motion in the radial direction, and thus the velocity component in the direction normal to the pipe axis is everywhere zero. There is no acceleration since the flow is steady and fully developed.

Now consider a ring-shaped differential volume element of radius  $r$ , thickness  $dr$ , and length  $dx$  oriented coaxially with the tube, as shown in Fig. 8–17. The volume element involves only pressure and viscous effects and thus the pressure and shear forces must balance each other. The pressure force acting on a submerged plane surface is the product of the pressure at the centroid of the surface and the surface area. A force balance on the volume element in the flow direction gives

$$(2\pi r dr P)_x - (2\pi r dr P)_{x+dx} + (2\pi r dx \tau)_r - (2\pi r dx \tau)_{r+dr} = 0 \quad (8-34)$$

FIGURE 8–17

Free-body diagram of a ring-shaped differential fluid element of radius  $r$ , thickness  $dr$ , and length  $dx$  oriented coaxially with a horizontal tube in fully developed laminar flow.

Force balance:

$$\pi R^2 P - \pi R^2 (P + dP) - 2\pi R dx \tau_w = 0$$

Simplifying:

$$\frac{dP}{dx} = -\frac{2\tau_w}{R}$$

**FIGURE 8-18**

Free-body diagram of a fluid disk element of radius  $R$  and length  $dx$  in fully developed laminar flow in a horizontal tube.

which indicates that in fully developed flow in a horizontal tube, the viscous and pressure forces balance each other. Dividing by  $2\pi dr dx$  and rearranging,

$$r \frac{P_{x+dx} - P_x}{dx} + \frac{(r\tau)_{r+dr} - (r\tau)_r}{dr} = 0 \quad (8-35)$$

Taking the limit as  $dr, dx \rightarrow 0$  gives

$$r \frac{dP}{dx} + \frac{d(r\tau)}{dr} = 0 \quad (8-36)$$

Substituting  $\tau = -\mu(du/dr)$  and taking  $\mu = \text{constant}$  gives the desired equation,

$$\frac{\mu}{r} \frac{d}{dr} \left( r \frac{du}{dr} \right) = \frac{dP}{dx} \quad (8-37)$$

The quantity  $du/dr$  is negative in pipe flow, and the negative sign is included to obtain positive values for  $\tau$ . (Or,  $du/dr = -du/dy$  since  $y = R - r$ .) The left side of Eq. 8-37 is a function of  $r$ , and the right side is a function of  $x$ . The equality must hold for any value of  $r$  and  $x$ , and an equality of the form  $f(r) = g(x)$  can be satisfied only if both  $f(r)$  and  $g(x)$  are equal to the same constant. Thus we conclude that  $dP/dx = \text{constant}$ . This can be verified by writing a force balance on a volume element of radius  $R$  and thickness  $dx$  (a slice of the tube), which gives (Fig. 8-18)

$$\frac{dP}{dx} = -\frac{2\tau_w}{R}$$

Here  $\tau_w$  is constant since the viscosity and the velocity profile are constants in the fully developed region. Therefore,  $dP/dx = \text{constant}$ .

Equation 8-37 is solved by rearranging and integrating it twice to give

$$u(r) = \frac{1}{4\mu} \left( \frac{dP}{dx} \right) + C_1 \ln r + C_2 \quad (8-38)$$

The velocity profile  $u(r)$  is obtained by applying the boundary conditions  $\partial u / \partial r = 0$  at  $r = 0$  (because of symmetry about the centerline) and  $u = 0$  at  $r = R$  (the no-slip condition at the tube wall). We get

$$u(r) = -\frac{R^2}{4\mu} \left( \frac{dP}{dx} \right) \left( 1 - \frac{r^2}{R^2} \right) \quad (8-39)$$

Therefore, the velocity profile in fully developed laminar flow in a tube is *parabolic* with a maximum at the centerline and a minimum (zero) at the tube wall. Also, the axial velocity  $u$  is positive for any  $r$ , and thus the axial pressure gradient  $dP/dx$  must be negative (i.e., pressure must decrease in the flow direction because of viscous effects).

The average velocity is determined from its definition by substituting Eq. 8-39 into Eq. 8-2, and performing the integration, yielding

$$V_{\text{avg}} = \frac{2}{R^2} \int_0^R u(r) r dr = \frac{-2}{R^2} \int_0^R \frac{R^2}{4\mu} \left( \frac{dP}{dx} \right) \left( 1 - \frac{r^2}{R^2} \right) r dr = -\frac{R^2}{8\mu} \left( \frac{dP}{dx} \right) \quad (8-40)$$

Combining the last two equations, the velocity profile is rewritten as

$$u(r) = 2V_{\text{avg}} \left(1 - \frac{r^2}{R^2}\right) \quad (8-41)$$

This is a convenient form for the velocity profile since  $V_{\text{avg}}$  can be determined easily from the flow rate information.

The maximum velocity occurs at the centerline and is determined from Eq. 8-41 by substituting  $r = 0$ ,

$$u_{\text{max}} = 2V_{\text{avg}} \quad (8-42)$$

Therefore, *the average velocity in fully developed laminar pipe flow is one-half of the maximum velocity.*

## Pressure Drop

A quantity of interest in the analysis of pipe flow is the *pressure drop*  $\Delta P$  since it is directly related to the power requirements of the fan or pump to maintain flow. We note that  $dP/dx = \text{constant}$ , and integrating from  $x = x_1$  where the pressure is  $P_1$  to  $x = x_1 + L$  where the pressure is  $P_2$  gives

$$\frac{dP}{dx} = \frac{P_2 - P_1}{L} \quad (8-43)$$

Substituting Eq. 8-43 into the  $V_{\text{avg}}$  expression in Eq. 8-40, the pressure drop is expressed as

$$\text{Laminar flow: } \Delta P = P_1 - P_2 = \frac{8\mu LV_{\text{avg}}}{R^2} = \frac{32\mu LV_{\text{avg}}}{D^2} \quad (8-44)$$

The symbol  $\Delta$  is typically used to indicate the difference between the final and initial values, like  $\Delta y = y_2 - y_1$ . But in fluid flow,  $\Delta P$  is used to designate pressure drop, and thus it is  $P_1 - P_2$ . A pressure drop due to viscous effects represents an irreversible pressure loss, and it is called **pressure loss**  $\Delta P_L$  to emphasize that it is a *loss* (just like the head loss  $h_L$ , which as we shall see is proportional to  $\Delta P$ ).

Note from Eq. 8-44 that the pressure drop is proportional to the viscosity  $\mu$  of the fluid, and  $\Delta P$  would be zero if there were no friction. Therefore, the drop of pressure from  $P_1$  to  $P_2$  in this case is due entirely to viscous effects, and Eq. 8-44 represents the pressure loss  $\Delta P_L$  when a fluid of viscosity  $\mu$  flows through a pipe of constant diameter  $D$  and length  $L$  at average velocity  $V_{\text{avg}}$ .

In practice, it is convenient to express the pressure loss for all types of fully developed internal flows (laminar or turbulent flows, circular or noncircular pipes, smooth or rough surfaces, horizontal or inclined pipes) as (Fig. 8-19)

$$\text{Pressure loss: } \Delta P_L = f \frac{L}{D} \frac{\rho V_{\text{avg}}^2}{2} \quad (8-45)$$

where  $\rho V_{\text{avg}}^2/2$  is the *dynamic pressure* and  $f$  is the **Darcy friction factor**,

$$f = \frac{8\tau_w}{\rho V_{\text{avg}}^2}$$

It is also called the **Darcy–Weisbach friction factor**, named after the Frenchman Henry Darcy (1803–1858) and the German Julius Weisbach (1806–1871), the two engineers who provided the greatest contribution in its

**FIGURE 8-19**

The relation for pressure loss (and head loss) is one of the most general relations in fluid mechanics, and it is valid for laminar or turbulent flows, circular or noncircular tubes, and pipes with smooth or rough surfaces.

development. It should not be confused with the *friction coefficient*  $C_f$  [also called the *Fanning friction factor*, named after the American engineer John Fanning (1837–1911)], which is defined as  $C_f = 2\tau_w/(\rho V_{avg}^2) = f/4$ .

Setting Eqs. 8–44 and 8–45 equal to each other and solving for  $f$  gives the friction factor for fully developed laminar flow in a circular tube,

$$\text{Circular tube, laminar: } f = \frac{64\mu}{\rho DV_{avg}} = \frac{64}{Re} \quad (8-46)$$

This equation shows that *in laminar flow, the friction factor is a function of the Reynolds number only and is independent of the roughness of the pipe surface.*

In the analysis of piping systems, pressure losses are commonly expressed in terms of the *equivalent fluid column height*, called the **head loss**  $h_L$ . Noting from fluid statics that  $\Delta P = \rho gh$  and thus a pressure difference of  $\Delta P$  corresponds to a fluid height of  $h = \Delta P/\rho g$ , the *pipe head loss* is obtained by dividing  $\Delta P_L$  by  $\rho g$  to give

$$h_L = \frac{\Delta P_L}{\rho g} = f \frac{L}{D} \frac{V_{avg}^2}{2g}$$

The head loss  $h_L$  represents *the additional height that the fluid needs to be raised by a pump in order to overcome the frictional losses in the pipe.* The head loss is caused by viscosity, and it is directly related to the wall shear stress. Equation 8–45 is valid for both laminar and turbulent flows in both circular and noncircular tubes, but Eq. 8–46 is valid only for fully developed laminar flow in circular pipes.

Once the pressure loss (or head loss) is known, the required pumping power to overcome the pressure loss is determined from

$$\dot{W}_{pump,L} = \dot{V}\Delta P_L = \dot{V}\rho gh_L = \dot{m}gh_L \quad (8-47)$$

where  $\dot{V}$  is the volume flow rate and  $\dot{m}$  is the mass flow rate.

The average velocity for laminar flow in a horizontal tube is, from Eq. 8–44,

$$\text{Horizontal tube: } V_{avg} = \frac{(P_1 - P_2)R^2}{8\mu L} = \frac{(P_1 - P_2)D^2}{32\mu L} = \frac{\Delta P D^2}{32\mu L}$$

Then the volume flow rate for laminar flow through a horizontal tube of diameter  $D$  and length  $L$  becomes

$$\dot{V} = V_{avg} A_c = \frac{(P_1 - P_2)R^2}{8\mu L} \pi R^2 = \frac{(P_1 - P_2)\pi D^4}{128\mu L} = \frac{\Delta P \pi D^4}{128\mu L} \quad (8-48)$$

This equation is known as **Poiseuille's law**, and this flow is called *Hagen–Poiseuille flow* in honor of the works of G. Hagen (1797–1884) and J. Poiseuille (1799–1869) on the subject. Note from Eq. 8–48 that *for a specified flow rate, the pressure drop and thus the required pumping power is proportional to the length of the pipe and the viscosity of the fluid, but it is inversely proportional to the fourth power of the radius (or diameter) of the pipe.* Therefore, the pumping power requirement for a piping system can be reduced by a factor of 16 by doubling the tube diameter (Fig. 8–20). Of course the benefits of the reduction in the energy costs must be weighed against the increased cost of construction due to using a larger-diameter tube.

The pressure drop  $\Delta P$  equals the pressure loss  $\Delta P_L$  in the case of a horizontal tube, but this is not the case for inclined pipes or pipes with variable cross-sectional area because of the changes in elevation and velocity.

**FIGURE 8-20**

The pumping power requirement for a laminar flow piping system can be reduced by a factor of 16 by doubling the tube diameter.

## Temperature Profile and the Nusselt Number

In the previous analysis, we have obtained the velocity profile for fully developed flow in a circular tube from a force balance applied on a volume element, and determined the friction factor and the pressure drop. Below we obtain the energy equation by applying the energy balance on a differential volume element, and solve it to obtain the temperature profile for the constant surface temperature and the constant surface heat flux cases.

Reconsider steady laminar flow of a fluid in a circular tube of radius  $R$ . The fluid properties  $\rho$ ,  $k$ , and  $c_p$  are constant, and the work done by viscous forces is negligible. The fluid flows along the  $x$ -axis with velocity  $u$ . The flow is fully developed so that  $u$  is independent of  $x$  and thus  $u = u(r)$ . Noting that energy is transferred by mass in the  $x$ -direction, and by conduction in the  $r$ -direction (heat conduction in the  $x$ -direction is assumed to be negligible), the steady-flow energy balance for a cylindrical shell element of thickness  $dr$  and length  $dx$  can be expressed as (Fig. 8-21)

$$\dot{m}c_pT_x - \dot{m}c_pT_{x+dx} + \dot{Q}_r - \dot{Q}_{r+dr} = 0 \quad (8-49)$$

where  $\dot{m} = \rho u A_c = \rho u (2\pi r dr)$ . Substituting and dividing by  $2\pi r dr dx$  gives, after rearranging,

$$\rho c_p u \frac{T_{x+dx} - T_x}{dx} = -\frac{1}{2\pi r dx} \frac{\dot{Q}_{r+dr} - \dot{Q}_r}{dr} \quad (8-50)$$

or

$$u \frac{\partial T}{\partial x} = -\frac{1}{2\rho c_p \pi r dx} \frac{\partial \dot{Q}}{\partial r} \quad (8-51)$$

But from Fourier's law of heat conduction in the radial direction

$$\frac{\partial \dot{Q}}{\partial r} = \frac{\partial}{\partial r} \left( -2\pi k dx \frac{\partial T}{\partial r} \right) = -2\pi k dx \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) \quad (8-52)$$

Substituting and using  $\alpha = k/\rho c_p$  gives

$$u \frac{\partial T}{\partial x} = \frac{\alpha}{r} \frac{\partial}{\partial r} \left( r \frac{\partial T}{\partial r} \right) \quad (8-53)$$

which states that *the rate of net energy transfer to the control volume by mass flow is equal to the net rate of heat conduction in the radial direction.*

## Constant Surface Heat Flux

For fully developed flow in a circular tube subjected to constant surface heat flux, we have, from Eq. 8-24,

$$\frac{\partial T}{\partial x} = \frac{dT_s}{dx} = \frac{dT_m}{dx} = \frac{2\dot{q}_s}{\rho V_{avg} c_p R} = \text{constant} \quad (8-54)$$

If heat conduction in the  $x$ -direction were considered in the derivation of Eq. 8-53, it would give an additional term  $\alpha \partial^2 T / \partial x^2$ , which would be equal to zero since  $\partial T / \partial x = \text{constant}$  and thus  $T = T(r)$ . Therefore, the assumption that there is no axial heat conduction is satisfied exactly in this case.

**FIGURE 8-21**

The differential volume element used in the derivation of energy balance relation.

Substituting Eq. 8–54 and the relation for velocity profile (Eq. 8–41) into Eq. 8–53 gives

$$\frac{4\dot{q}_s}{kR} \left(1 - \frac{r^2}{R^2}\right) = \frac{1}{r} \frac{d}{dr} \left(r \frac{dT}{dr}\right) \quad (8-55)$$

which is a second-order ordinary differential equation. Its general solution is obtained by separating the variables and integrating twice to be

$$T = \frac{\dot{q}_s}{kR} \left(r^2 - \frac{r^4}{4R^2}\right) + C_1 \ln r + C_2 \quad (8-56)$$

The desired solution to the problem is obtained by applying the boundary conditions  $\partial T/\partial r = 0$  at  $r = 0$  (because of symmetry) and  $T = T_s$  at  $r = R$ . We get

$$T = T_s - \frac{\dot{q}_s R}{k} \left(\frac{3}{4} - \frac{r^2}{R^2} + \frac{r^4}{4R^4}\right) \quad (8-57)$$

The mean temperature  $T_m$  is determined by substituting the velocity and temperature profile relations (Eqs. 8–41 and 8–57) into Eq. 8–4 and performing the integration. It gives

$$T_m = T_s - \frac{11}{24} \frac{\dot{q}_s R}{k} \quad (8-58)$$

Combining this relation with  $\dot{q}_s = h(T_s - T_m)$  gives

$$h = \frac{24}{11} \frac{k}{R} = \frac{48}{11} \frac{k}{D} = 4.36 \frac{k}{D} \quad (8-59)$$

or

$$\text{Circular tube, laminar } (\dot{q}_s = \text{constant}): \quad \text{Nu} = \frac{hD}{k} = 4.36 \quad (8-60)$$

Therefore, for fully developed laminar flow in a circular tube subjected to constant surface heat flux, the Nusselt number is a constant. There is no dependence on the Reynolds or the Prandtl numbers.

## Constant Surface Temperature

A similar analysis can be performed for fully developed laminar flow in a circular tube for the case of constant surface temperature  $T_s$ . The solution procedure in this case is more complex as it requires iterations, but the Nusselt number relation obtained is equally simple (Fig. 8–22):

$$\text{Circular tube, laminar } (T_s = \text{constant}): \quad \text{Nu} = \frac{hD}{k} = 3.66 \quad (8-61)$$

Comparison of Eqs. 8–60 and 8–61 shows that the Nusselt number for the case of constant surface heat flux is 16 percent higher than the case of constant surface temperature for the fully developed laminar pipe flow. This shows that laminar flow is sensitive to the applied surface thermal boundary condition and for applications requiring higher rates of heat transfer, whenever possible; the constant surface heat flux boundary condition should be used. This is contrary to the results shown in Fig. 8–9 for the turbulent flow,

**FIGURE 8–22**

In laminar flow in a tube with constant surface temperature, both the *friction factor* and the *heat transfer coefficient* remain constant in the fully developed region.

which showed no sensitivity to the different surface thermal boundary conditions in the fully developed region.

The thermal conductivity  $k$  for use in the Nu relations above should be evaluated at the bulk mean fluid temperature, which is the arithmetic average of the mean fluid temperatures at the inlet and the exit of the tube. For laminar flow, the effect of *surface roughness* on the friction factor and the heat transfer coefficient is negligible.

## Laminar Flow in Noncircular Tubes

The friction factor  $f$  and the Nusselt number relations are given in Table 8–1 for *fully developed laminar flow* in tubes of various cross sections. The Reynolds and Nusselt numbers for flow in these tubes are based on the hydraulic diameter  $D_h = 4A_c/p$ , where  $A_c$  is the cross-sectional area of the tube and  $p$  is its perimeter. Once the Nusselt number is available, the convection heat transfer coefficient is determined from  $h = k\text{Nu}/D_h$ .

**TABLE 8–1**

Nusselt number and friction factor for fully developed laminar flow in tubes of various cross sections ( $D_h = 4A_c/p$ ,  $\text{Re} = V_{\text{avg}}D_h/\nu$ , and  $\text{Nu} = hD_h/k$ )

| Tube Geometry   | $a/b$<br>or $\theta^\circ$ | Nusselt Number        |                             | Friction Factor<br>$f$ |
|---|----------------------------|-----------------------|-----------------------------|------------------------|
|   |                            | $T_s = \text{Const.}$ | $\dot{q}_s = \text{Const.}$ |                        |

## Developing Laminar Flow in the Entrance Region

The heat transfer analysis presented so far has been for hydrodynamically and thermally developed (fully developed) laminar flow in a circular tube where conditions given by Eqs. 8–7 and 8–8 were valid. However, in the entrance region the energy equation Eq. 8–53 is no longer valid since in this region there is motion in the radial direction and the velocity profile  $u(r)$  changes in the flow direction. In addition, for example for the case of constant surface heat flux, the axial temperature gradient  $\partial T/\partial x$  can no longer be simplified through Eq. 8–54. Therefore, the solution to the energy equation in the entrance region is more complicated than the fully developed region and the energy equation is solved numerically. The local values of Nusselt number are typically presented either graphically or in tabular form in terms of the inverse of a dimensionless parameter called the Graetz number (Fig. 8–23) which is defined as  $Gz = (D/x)\text{RePr}$ . As shown in Fig. 8–24, the fully developed conditions for both cases of constant surface heat flux and constant surface temperature are reached for  $1/Gz = (x/D)/\text{RePr} \approx 0.05$ , which is consistent with the results given by Eq. 8–12 for laminar thermal entry length. Therefore, when the inverse of the Graetz number is greater than 0.05, the local Nusselt numbers approach their fully developed values of 4.36 for constant surface heat flux and 3.66 for constant surface temperature. Excellent treatments of this subject are contained in Shah and London (1978) and Shah and Bhatti (1987). Two different solutions are obtained in the literature. The simplest case is for hydrodynamically developed flow and thermally developing flow. The more complicated case is for hydrodynamically and thermally developing flow. In this case the solution is a function of the Prandtl number, and for each case the value of the Prandtl number must be specified a priori.

There are a limited number of empirical correlations available in the literature for the average Nusselt number under constant surface temperature boundary condition. For example for a circular tube of length  $L$  subjected to constant surface temperature, the average Nusselt number for the *thermal entrance region* can be determined from [Edwards et al., 1979]

$$\text{Entry region, laminar: } \text{Nu} = 3.66 + \frac{0.065(D/L)\text{Re Pr}}{1 + 0.04[(D/L)\text{Re Pr}]^{2/3}} \quad (8-62)$$

Note that the average Nusselt number is larger at the entrance region, as expected, and it approaches asymptotically to the fully developed value of 3.66 as  $L \rightarrow \infty$ . This relation assumes that the flow is hydrodynamically developed when the fluid enters the heating section, but it can also be used for flow developing hydrodynamically when  $\text{Pr} \geq 5$ .

When the difference between the surface and the fluid temperatures is large, it may be necessary to account for the variation of viscosity with temperature.

The average Nusselt number for hydrodynamically and thermally developing laminar flow in a circular tube in that case can be determined from [Sieder and Tate (1936)]

$$\text{Entry region, laminar: } \text{Nu} = 1.86 \left( \frac{\text{Re Pr } D}{L} \right)^{1/3} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad (8-63)$$

The above equation is recommended for  $0.60 \leq \text{Pr} \leq 5$  and  $0.0044 \leq (\mu_b/\mu_s) \leq 9.75$ . Note that the term  $(D/L)\text{RePr}$  in both Eqs. 8–62 and 8–63 is the Graetz number for a circular tube of length  $L$ . All properties appearing in Eqs. 8–62 and 8–63 should be evaluated at the bulk mean fluid temperature,  $T_b = (T_i + T_e)/2$ , except for  $\mu_s$ , which is evaluated at the surface temperature.

The average Nusselt number for the thermal entrance region of flow between *isothermal parallel plates* of length  $L$  is expressed as (Edwards et al., 1979)

$$\text{Entry region, laminar: } \text{Nu} = 7.54 + \frac{0.03(D_h/L)\text{Re Pr}}{1 + 0.016[(D_h/L)\text{Re Pr}]^{2/3}} \quad (8-64)$$

where  $D_h$  is the hydraulic diameter, which is twice the spacing of the plates. This relation can be used for  $\text{Re} \leq 2800$ .

### EXAMPLE 8–2 Average Velocity and Temperature in Laminar Tube Flow

The velocity and temperature profiles for a fluid flowing in a circular tube of inner radius  $R = 4 \text{ cm}$  (Fig. 8–25) are given as

$$u(r) = 0.2[1 - (r/R)^2] \quad (\text{in m/s})$$

$$T(r) = 250 + 200(r/R)^3 \quad (\text{in K})$$

Determine the average flow velocity and the average fluid temperature in the tube.

**SOLUTION** Using the given velocity and temperatures profiles in a tube, the average flow velocity and the average fluid temperature are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 Properties are constant.

**Analysis** On the basis of the conservation of mass principle, the average velocity in a circular tube of inner radius  $R$  is expressed as

$$V_{\text{avg}} = \frac{2}{R^2} \int_0^R u(r)r dr$$

Substituting the known quantities and performing the integration, the average velocity is determined to be

$$V_{\text{avg}} = \frac{2}{R^2} \int_0^R 0.2 \left( r - \frac{r^3}{R^2} \right) dr = \frac{2 \times 0.2}{R^2} \left( \frac{r^2}{2} - \frac{r^4}{4R^2} \right)_0^R = \frac{2 \times 0.2}{R^2} \left( \frac{R^2}{4} \right) = 0.1 \text{ m/s}$$

On the basis of the conservation of energy principle, the average (or mean) fluid temperature at a cross section is expressed as

$$T_m = \frac{2}{V_{\text{avg}} R^2} \int_0^R T(r)u(r)r dr$$

FIGURE 8–24

Local Nusselt numbers in the entry and fully developed regions for laminar flow in a circular tube for hydrodynamically developed and thermally developing flow.

FIGURE 8–25

Schematic for Example 8–2.

Substituting the known quantities and performing the integration, the average temperature is determined to be

$$\begin{aligned} T_m &= \frac{2}{V_{\text{avg}}R^2} \int_0^R 0.2 \left(1 - \frac{r^2}{R^2}\right) \left(250 + 200 \frac{r^3}{R^3}\right) r dr \\ &= \frac{2 \times 0.2}{V_{\text{avg}}R^2} \left(250 \frac{r^2}{2} - 250 \frac{r^4}{4R^2} + 200 \frac{r^5}{5R^3} - 200 \frac{r^7}{7R^5}\right)_0^R \\ &= \frac{2 \times 0.2}{V_{\text{avg}}R^2} \left(\frac{250R^2}{2} - \frac{250R^2}{4} + \frac{200R^2}{5} - \frac{200R^2}{7}\right) = \frac{2 \times 0.2 \times 73.93}{0.1} = 295.7 \text{ K} \end{aligned}$$

**Discussion** The velocity profile for laminar flow is expressed as  $u(r) = 2V_{\text{avg}}[1 - (r/R)^2]$ . Comparing this with the given profile  $u(r) = 0.2[1 - (r/R)^2]$ , we could obtain the same value of average velocity directly by observation. Also, the parabolic velocity profile indicates that this is a fully developed laminar flow.

FIGURE 8-26

Schematic for Example 8-3.

### EXAMPLE 8-3 Flow of Oil in a Pipeline through a Lake

Consider the flow of oil at  $20^\circ\text{C}$  in a 30-cm-diameter pipeline at an average velocity of  $2 \text{ m/s}$  (Fig. 8-26). A 200-m-long section of the horizontal pipeline passes through icy waters of a lake at  $0^\circ\text{C}$ . Measurements indicate that the surface temperature of the pipe is very nearly  $0^\circ\text{C}$ . Disregarding the thermal resistance of the pipe material, determine (a) the temperature of the oil when the pipe leaves the lake, (b) the rate of heat transfer from the oil, and (c) the pumping power required to overcome the pressure losses and to maintain the flow of the oil in the pipe.

**SOLUTION** Oil flows in a pipeline that passes through icy waters of a lake at  $0^\circ\text{C}$ . The exit temperature of the oil, the rate of heat loss, and the pumping power needed to overcome pressure losses are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The surface temperature of the pipe is very nearly  $0^\circ\text{C}$ . 3 The thermal resistance of the pipe is negligible. 4 The inner surfaces of the pipeline are smooth. 5 The flow is hydrodynamically developed when the pipeline reaches the lake.

**Properties** We do not know the exit temperature of the oil, and thus we cannot determine the bulk mean temperature, which is the temperature at which the properties of oil are to be evaluated. The mean temperature of the oil at the inlet is  $20^\circ\text{C}$ , and we expect this temperature to drop somewhat as a result of heat loss to the icy waters of the lake. We evaluate the properties of the oil at the inlet temperature, but we will repeat the calculations, if necessary, using properties at the evaluated bulk mean temperature. At  $20^\circ\text{C}$  we read (Table A-13)

$$\begin{aligned} \rho &= 888.1 \text{ kg/m}^3 & \nu &= 9.429 \times 10^{-4} \text{ m}^2/\text{s} \\ k &= 0.145 \text{ W/m}\cdot\text{K} & c_p &= 1880 \text{ J/kg}\cdot\text{K} & \text{Pr} &= 10,863 \end{aligned}$$

**Analysis** (a) The Reynolds number is

$$\text{Re} = \frac{V_{\text{avg}}D}{\nu} = \frac{(2 \text{ m/s})(0.3 \text{ m})}{9.429 \times 10^{-4} \text{ m}^2/\text{s}} = 636$$

which is less than the critical Reynolds number of 2300. Therefore, the flow is laminar, and the thermal entry length in this case is roughly

$$L_t \approx 0.05 \text{ Re Pr } D = 0.05 \times 636 \times 10,863 \times (0.3 \text{ m}) \approx 103,600 \text{ m}$$

which is much greater than the total length of the pipe. This is typical of fluids with high Prandtl numbers. Therefore, we assume thermally developing flow and determine the Nusselt number from

$$\begin{aligned} \text{Nu} &= \frac{hD}{k} = 3.66 + \frac{0.065(D/L) \text{ Re Pr}}{1 + 0.04[(D/L) \text{ Re Pr}]^{2/3}} \\ &= 3.66 + \frac{0.065(0.3/200) \times 636 \times 10,863}{1 + 0.04[(0.3/200) \times 636 \times 10,863]^{2/3}} \\ &= 33.7 \end{aligned}$$

Note that this Nusselt number is considerably higher than the fully developed value of 3.66. Then,

$$h = \frac{k}{D} \text{ Nu} = \frac{0.145 \text{ W/m}\cdot\text{K}}{0.3 \text{ m}} (33.7) = 16.3 \text{ W/m}^2\cdot\text{K}$$

Also,

$$\begin{aligned} A_s &= \pi DL = \pi(0.3 \text{ m})(200 \text{ m}) = 188.5 \text{ m}^2 \\ \dot{m} &= \rho A_c V_{\text{avg}} = (888.1 \text{ kg/m}^3)[\frac{1}{4}\pi(0.3 \text{ m})^2](2 \text{ m/s}) = 125.6 \text{ kg/s} \end{aligned}$$

Next we determine the exit temperature of oil,

$$\begin{aligned} T_e &= T_s - (T_s - T_i) \exp(-hA_s/\dot{m}c_p) \\ &= 0^\circ\text{C} - [(0 - 20)^\circ\text{C}] \exp\left[-\frac{(16.3 \text{ W/m}^2\cdot\text{K})(188.5 \text{ m}^2)}{(125.6 \text{ kg/s})(1881 \text{ J/kg}\cdot\text{K})}\right] \\ &= \mathbf{19.74^\circ\text{C}} \end{aligned}$$

Thus, the mean temperature of oil drops by a mere  $0.26^\circ\text{C}$  as it crosses the lake. This makes the bulk mean oil temperature  $19.87^\circ\text{C}$ , which is practically identical to the inlet temperature of  $20^\circ\text{C}$ . Therefore, we do not need to reevaluate the properties.

(b) The log mean temperature difference and the rate of heat loss from the oil are

$$\Delta T_{\text{lm}} = \frac{T_i - T_e}{\ln \frac{T_s - T_e}{T_s - T_i}} = \frac{20 - 19.74}{\ln \frac{0 - 19.74}{0 - 20}} = -19.87^\circ\text{C}$$

$$\dot{Q} = hA_s \Delta T_{\text{lm}} = (16.3 \text{ W/m}^2\cdot\text{K})(188.5 \text{ m}^2)(-19.87^\circ\text{C}) = \mathbf{-6.11 \times 10^4 \text{ W}}$$

Therefore, the oil will lose heat at a rate of  $61.1 \text{ kW}$  as it flows through the pipe in the icy waters of the lake. Note that  $\Delta T_{\text{lm}}$  is identical to the arithmetic mean temperature in this case, since  $\Delta T_i \approx \Delta T_e$ .

(c) The laminar flow of oil is hydrodynamically developed. Therefore, the friction factor can be determined from

$$f = \frac{64}{\text{Re}} = \frac{64}{636} = 0.1006$$

Then the pressure drop in the pipe and the required pumping power become

$$\Delta P = f \frac{L}{D} \frac{\rho V_{\text{avg}}^2}{2} = 0.1006 \frac{200 \text{ m}}{0.3 \text{ m}} \frac{(888.1 \text{ kg/m}^3)(2 \text{ m/s})^2}{2} = 1.19 \times 10^5 \text{ N/m}^2$$

$$\dot{W}_{\text{pump}} = \frac{\dot{m} \Delta P}{\rho} = \frac{(125.6 \text{ kg/s})(1.19 \times 10^5 \text{ N/m}^2)}{888.1 \text{ kg/m}^3} = 16.8 \text{ kW}$$

**Discussion** We need a 16.8-kW pump just to overcome the friction in the pipe as the oil flows in the 200-m-long pipe through the lake.

## 8–6 • TURBULENT FLOW IN TUBES

We mentioned earlier that flow in smooth tubes is usually fully turbulent for  $\text{Re} > 10,000$ . Turbulent flow is commonly utilized in practice because of the higher heat transfer coefficients associated with it. Most correlations for the friction and heat transfer coefficients in turbulent flow are based on experimental studies because of the difficulty in dealing with turbulent flow theoretically.

For *smooth* tubes, the friction factor in turbulent flow can be determined from the explicit *first Petukhov equation* [Petukhov (1970)] given as

$$\text{Smooth tubes: } f = (0.790 \ln \text{Re} - 1.64)^{-2} \quad 3000 < \text{Re} < 5 \times 10^6 \quad (8-65)$$

The Nusselt number in turbulent flow is related to the friction factor through the *Chilton–Colburn analogy* expressed as

$$\text{Nu} = 0.125 f \text{RePr}^{1/3} \quad (8-66)$$

Once the friction factor is available, this equation can be used conveniently to evaluate the Nusselt number for both smooth and rough tubes.

For fully developed turbulent flow in *smooth tubes*, a simple relation for the Nusselt number can be obtained by substituting the simple power law relation  $f = 0.184 \text{ Re}^{-0.2}$  for the friction factor into Eq. 8–66. It gives

$$\text{Nu} = 0.023 \text{ Re}^{0.8} \text{ Pr}^{1/3} \quad \begin{cases} (0.7 \leq \text{Pr} \leq 160) \\ (\text{Re} > 10,000) \end{cases} \quad (8-67)$$

which is known as the *Colburn equation*. The accuracy of this equation can be improved by modifying it as

$$\text{Nu} = 0.023 \text{ Re}^{0.8} \text{ Pr}^n \quad (8-68)$$

where  $n = 0.4$  for *heating* and  $0.3$  for *cooling* of the fluid flowing through the tube. This equation is known as the *Dittus–Boelter equation* [Dittus and Boelter (1930)] and it is preferred over the Colburn equation.

The preceding equations can be used when the temperature difference between the fluid and wall surface is not large by evaluating all fluid properties at the *bulk mean fluid temperature*  $T_b = (T_i + T_e)/2$ . When the variation in properties is large due to a large temperature difference, the following equation due to Sieder and Tate (1936) can be used:

$$\text{Nu} = 0.027 \text{ Re}^{0.8} \text{ Pr}^{1/3} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad \begin{cases} (0.7 \leq \text{Pr} \leq 16,700) \\ (\text{Re} \geq 10,000) \end{cases} \quad (8-69)$$

Here all properties are evaluated at  $T_b$  except  $\mu_s$ , which is evaluated at  $T_s$ .

The Nusselt number relations above are fairly simple, but they may give errors as large as 25 percent. This error can be reduced considerably to less than 10 percent by using more complex but accurate relations such as the *second Petukhov equation* expressed as

$$\text{Nu} = \frac{(f/8)\text{Re Pr}}{1.07 + 12.7(f/8)^{0.5} (\text{Pr}^{2/3} - 1)} \quad \begin{cases} 0.5 \leq \text{Pr} \leq 2000 \\ 10^4 < \text{Re} < 5 \times 10^6 \end{cases} \quad (8-70)$$

The accuracy of this relation at lower Reynolds numbers is improved by modifying it as [Gnielinski (1976)]

$$\text{Nu} = \frac{(f/8)(\text{Re} - 1000) \text{Pr}}{1 + 12.7(f/8)^{0.5} (\text{Pr}^{2/3} - 1)} \quad \begin{cases} 0.5 \leq \text{Pr} \leq 2000 \\ 3 \times 10^3 < \text{Re} < 5 \times 10^6 \end{cases} \quad (8-71)$$

where the friction factor  $f$  can be determined from an appropriate relation such as the first Petukhov equation. Gnielinski's equation should be preferred in calculations. Again properties should be evaluated at the bulk mean fluid temperature.

The relations above are not very sensitive to the *thermal conditions* at the tube surfaces and can be used for both  $T_s = \text{constant}$  and  $\dot{q}_s = \text{constant}$  cases. Despite their simplicity, the correlations already presented give sufficiently accurate results for most engineering purposes. They can also be used to obtain rough estimates of the friction factor and the heat transfer coefficients in the transition region.

The relations given so far do not apply to liquid metals because of their very low Prandtl numbers. For liquid metals ( $0.004 < \text{Pr} < 0.01$ ), the following relations are recommended by Sleicher and Rouse (1975) for  $10^4 < \text{Re} < 10^6$ :

$$\text{Liquid metals, } T_s = \text{constant: } \text{Nu} = 4.8 + 0.0156 \text{Re}^{0.85} \text{Pr}_s^{0.93} \quad (8-72)$$

$$\text{Liquid metals, } \dot{q}_s = \text{constant: } \text{Nu} = 6.3 + 0.0167 \text{Re}^{0.85} \text{Pr}_s^{0.93} \quad (8-73)$$

where the subscript  $s$  indicates that the Prandtl number is to be evaluated at the surface temperature.

## Fully Developed Transitional Flow Heat Transfer

As mentioned in Section 8–2, there is a regime of fluid flow which is neither fully laminar nor fully turbulent. Generally, internal flows with Reynolds numbers less than 2300 are considered fully laminar. As the Reynolds number rises, it contains increasingly more turbulent motion until  $\text{Re} \sim 4000$ ; at this point, it is mostly turbulent. By the time the Reynolds number is increased to  $\sim 10,000$ , it is normally fully turbulent.

The methods to handle fully laminar and fully turbulent heat transfer have already been discussed, however in some cases; the flow is in this transitional zone. Fortunately, the methods for handling turbulent flow can easily be adopted to deal with in this region. A simple approach is discussed in detail in Abraham et al. (2011). The recommendation is to continue to use Gnielinski's (1976) correlation (Eq. 8–71) along with  $f$  values determined

from the following expressions for two common flow geometries, the round tube and the parallel plate channel. These correlations can be applied over the Reynolds number ranges listed and are reasonably accurate for any thermal boundary condition, including the uniform wall temperature and uniform wall heat flux cases. A slightly more accurate approach is available for transitional flows in round tubes [Abraham et al. (2009)] but for most engineering applications, the following expressions are suitable.

*Smooth round pipe:*

$$f = 3.03 \times 10^{-12} Re^3 - 3.67 \times 10^{-8} Re^2 + 1.46 \times 10^{-4} Re - 0.151 \quad (8-74)$$

which is valid for  $2300 < Re < 4500$

*Smooth, parallel-plate channel:*

$$f = -6.38 \times 10^{-13} Re^3 + 1.17 \times 10^{-8} Re^2 - 6.69 \times 10^{-5} Re + 0.147 \quad (8-75)$$

which is valid for  $2300 < Re < 8000$

As discussed in the Topic of Special Interest later in this chapter, a very detailed discussion is provided for transitional flows with particular emphasis on the entrance geometry and on the development region. That discussion also handles flows which may experience buoyant motion and property variations.

## Rough Surfaces

Any irregularity or roughness on the surface disturbs the laminar sublayer and affects the flow. Therefore, unlike laminar flow, the friction factor and the convection coefficient in turbulent flow are strong functions of surface roughness.

The friction factor in fully developed turbulent pipe flow depends on the Reynolds number and the **relative roughness**  $\epsilon/D$ , which is the ratio of the mean height of roughness of the pipe to the pipe diameter. The functional form of this dependence cannot be obtained from a theoretical analysis, and all available results are obtained from painstaking experiments using artificially roughened surfaces (usually by gluing sand grains of a known size on the inner surfaces of the pipes). Most such experiments were conducted by Prandtl's student J. Nikuradse in 1933, followed by the works of others. The friction factor was calculated from the measurements of the flow rate and the pressure drop.

The experimental results obtained are presented in tabular, graphical, and functional forms obtained by curve-fitting experimental data. In 1939, Cyril F. Colebrook (1910–1997) combined the available data for transition and turbulent flow in smooth as well as rough pipes into the following implicit relation known as the **Colebrook equation**:

$$\frac{1}{\sqrt{f}} = -2.0 \log \left( \frac{\epsilon/D}{3.7} + \frac{2.51}{Re \sqrt{f}} \right) \quad (\text{turbulent flow}) \quad (8-76)$$

We note that the logarithm in Eq. 8–76 is a base 10 rather than a natural logarithm. In 1942, the American engineer Hunter Rouse (1906–1996) verified Colebrook's equation and produced a graphical plot of  $f$  as a function of  $Re$  and the product  $Re \sqrt{f}$ . He also presented the laminar flow relation and a table of commercial pipe roughness. Two years later, Lewis F. Moody (1880–1953) redrew Rouse's diagram into the form commonly used today. The now famous **Moody chart** is given in the appendix as Fig. A–20. It presents the

Darcy friction factor for pipe flow as a function of the Reynolds number and  $\varepsilon/D$  over a wide range. It is probably one of the most widely accepted and used charts in engineering. Although it was developed for circular pipes, it can also be used for noncircular pipes by replacing the diameter with the hydraulic diameter.

For smooth pipes, the agreement between the Petukhov and Colebrook equations is very good. The friction factor is minimum for a smooth pipe (but still not zero because of the no-slip condition), and increases with roughness (Fig. 8-27).

Commercially available pipes are specified according to a **nominal diameter**. The nominal diameter does not necessarily indicate the actual inside diameter of the pipe (Table 8-2). Therefore, in calculations we should make sure to use the actual inside diameter of the pipe. For example, a 2-inch nominal size steel pipe has an actual inside diameter of 2.067 inches. Another specification is **pipe schedule**. Schedule is thickness of the inside diameter of the pipe. Schedule 40 is usually a standard thickness for most applications, which is normally 1/4-inch wall (Table 8-2). As the schedule number increases or decreases, so does the wall thickness. However, the outside diameter remains the same. Standard piping schedules are 10, 40, 80, 120, and 160.

Commercially available pipes differ from those used in the experiments in that the roughness of pipes in the market is not uniform and it is difficult to give a precise description of it. Equivalent roughness values for some commercial pipes are given in Table 8-3 as well as in the Moody chart. But it should be kept in mind that these values are for new pipes, and the relative roughness of pipes may increase with use as a result of corrosion, scale buildup, and precipitation. As a result, the friction factor may increase by a factor of 5 to 10. Actual operating conditions must be considered in the design of piping systems. Also, the Moody chart and its equivalent Colebrook equation involve several uncertainties (the roughness size, experimental error, curve fitting of data, etc.), and thus the results obtained should not be treated as "exact." They are usually considered to be accurate to  $\pm 15$  percent over the entire range in the figure.

The Colebrook equation is implicit in  $f$ , and thus the determination of the friction factor requires iteration. An approximate explicit relation for  $f$  was given by S. E. Haaland in 1983 as

$$\frac{1}{\sqrt{f}} \approx -1.8 \log \left[ \frac{6.9}{Re} + \left( \frac{\varepsilon/D}{3.7} \right)^{1.11} \right] \quad (8-77)$$

The results obtained from this relation are within 2 percent of those obtained from the Colebrook equation. If more accurate results are desired, Eq. 8-77 can be used as a good *first guess* in a Newton iteration when using a programmable calculator or a spreadsheet to solve for  $f$  with Eq. 8-76.

In turbulent flow, wall roughness increases the heat transfer coefficient  $h$  by a factor of 2 or more [Dipprey and Sabersky (1963)]. The convection heat transfer coefficient for rough tubes can be calculated approximately from the Nusselt number relations such as Eq. 8-71 by using the friction factor determined from the Moody chart or the Colebrook equation. However, this approach is not very accurate since there is no further increase in  $h$  with  $f$  for  $f > 4f_{\text{smooth}}$  [Norris (1970)] and correlations developed specifically for rough tubes should be used when more accuracy is desired.

| Relative Roughness, $\varepsilon/D$ | Friction Factor, $f$ |
|-------------------------------------|----------------------|
| 0.0*                                | 0.0119               |
| 0.00001                             | 0.0119               |
| 0.0001                              | 0.0134               |
| 0.0005                              | 0.0172               |
| 0.001                               | 0.0199               |
| 0.005                               | 0.0305               |
| 0.01                                | 0.0380               |

\*The uncertainty in these values can be as much as  $\pm 60$  percent.

## Developing Turbulent Flow in the Entrance Region

The entry lengths for turbulent flow are typically short, often just 10 tube diameters long, and thus the Nusselt number determined for fully developed turbulent flow can be used approximately for the entire tube. This simple approach gives reasonable results for pressure drop and heat transfer for long tubes and conservative results for short ones. Correlations for the friction and heat transfer coefficients for the entrance regions are available in the literature for better accuracy.

## Turbulent Flow in Noncircular Tubes

The velocity and temperature profiles in turbulent flow are nearly straight lines in the core region, and any significant velocity and temperature gradients occur in the viscous sublayer (Fig. 8–28). Despite the small thickness of the viscous sublayer (usually much less than 1 percent of the pipe diameter), the characteristics of the flow in this layer are very important since they set the stage for flow in the rest of the pipe. Therefore, pressure drop and heat transfer characteristics of turbulent flow in tubes are dominated by the very thin viscous sublayer next to the wall surface, and the shape of the core region is not of much significance. Consequently, the turbulent flow relations given above for circular tubes can also be used for noncircular tubes with reasonable accuracy by replacing the diameter  $D$  in the evaluation of the Reynolds number by the hydraulic diameter  $D_h = 4A_c/p$ .

## Flow through Tube Annulus

Some simple heat transfer equipments consist of two concentric tubes, and are properly called *double-tube heat exchangers* (Fig. 8–29). In such devices, one fluid flows through the tube while the other flows through the annular space. The governing differential equations for both flows are identical. Therefore, steady laminar flow through an annulus can be studied analytically by using suitable boundary conditions.

Consider a concentric annulus of inner diameter  $D_i$  and outer diameter  $D_o$ . The hydraulic diameter of the annulus is

$$D_h = \frac{4A_c}{p} = \frac{4\pi(D_o^2 - D_i^2)/4}{\pi(D_o + D_i)} = D_o - D_i$$

Annular flow is associated with two Nusselt numbers— $Nu_i$  on the inner tube surface and  $Nu_o$  on the outer tube surface—since it may involve heat transfer on both surfaces. The Nusselt numbers for fully developed laminar flow with one surface isothermal and the other adiabatic are given in Table 8–4. When Nusselt numbers are known, the convection coefficients for the inner and the outer surfaces are determined from

$$Nu_i = \frac{h_i D_h}{k} \quad \text{and} \quad Nu_o = \frac{h_o D_h}{k} \quad (8-78)$$

For fully developed turbulent flow, the inner and outer convection coefficients are approximately equal to each other, and the tube annulus can be treated as a noncircular duct with a hydraulic diameter of  $D_h = D_o - D_i$ . The Nusselt number in this case can be determined from a suitable turbulent flow

**FIGURE 8-28**

In turbulent flow, the velocity profile is nearly a straight line in the core region, and any significant velocity gradients occur in the viscous sublayer.

**FIGURE 8-29**

A double-tube heat exchanger that consists of two concentric tubes.

relation such as the Gnielinski equation. To improve the accuracy of Nusselt numbers obtained from these relations for annular flow, Petukhov and Roizen (1964) recommend multiplying them by the following correction factors when one of the tube walls is adiabatic and heat transfer is through the other wall:

$$F_i = 0.86 \left( \frac{D_i}{D_o} \right)^{-0.16} \quad (\text{outer wall adiabatic}) \quad (8-79)$$

$$F_o = 1 - 0.14 \left( \frac{D_i}{D_o} \right)^{0.6} \quad (\text{inner wall adiabatic}) \quad (8-80)$$

## Heat Transfer Enhancement

Tubes with rough surfaces have much higher heat transfer coefficients than tubes with smooth surfaces. Therefore, tube surfaces are often intentionally *roughened*, *corrugated*, or *finned* in order to *enhance* the convection heat transfer coefficient and thus the convection heat transfer rate (Fig. 8–30). Heat transfer in turbulent flow in a tube has been increased by as much as 400 percent by roughening the surface. Roughening the surface, of course, also increases the friction factor and thus the power requirement for the pump or the fan.

The convection heat transfer coefficient can also be increased by inducing pulsating flow by pulse generators, by inducing swirl by inserting a twisted tape into the tube, or by inducing secondary flows by coiling the tube.

### EXAMPLE 8–4 Pressure Drop in a Water Tube

Water at 60°F ( $\rho = 62.36 \text{ lbm/ft}^3$  and  $\mu = 7.536 \times 10^{-4} \text{ lbm/ft}\cdot\text{s}$ ) is flowing steadily in a 2-in-internal-diameter horizontal tube made of stainless steel at a rate of 0.2 ft<sup>3</sup>/s (Fig. 8–31). Determine the pressure drop and the required pumping power input for flow through a 200-ft-long section of the tube.

**SOLUTION** The flow rate through a specified water tube is given. The pressure drop and the pumping power requirements are to be determined.

**Assumptions** 1 The flow is steady and incompressible. 2 The entrance effects are negligible, and thus the flow is fully developed. 3 The tube involves no components such as bends, valves, and connectors. 4 The piping section involves no work devices such as a pump or a turbine.

**Properties** The density and dynamic viscosity of water are given to be  $\rho = 62.36 \text{ lbm/ft}^3$  and  $\mu = 7.536 \times 10^{-4} \text{ lbm/ft}\cdot\text{s}$ . For stainless steel,  $\varepsilon = 0.000007 \text{ ft}$  (Table 8–3).

**Analysis** First we calculate the mean velocity and the Reynolds number to determine the flow regime:

$$V = \frac{\dot{V}}{A_c} = \frac{\dot{V}}{\pi D^2/4} = \frac{0.2 \text{ ft}^3/\text{s}}{\pi(2/12 \text{ ft})^2/4} = 9.17 \text{ ft/s}$$

$$\text{Re} = \frac{\rho V D}{\mu} = \frac{(62.36 \text{ lbm/ft}^3)(9.17 \text{ ft/s})(2/12 \text{ ft})}{7.536 \times 10^{-4} \text{ lbm/ft}\cdot\text{s}} = 126,400$$

TABLE 8–4

Nusselt number for fully developed laminar flow in an annulus with one surface isothermal and the other adiabatic (Kays and Perkins, 1972)

| $D_i/D_o$ | $\text{Nu}_i$ | $\text{Nu}_o$ |
|-----------|---------------|---------------|
| 0         | —             | 3.66          |
| 0.05      | 17.46         | 4.06          |
| 0.10      | 11.56         | 4.11          |
| 0.25      | 7.37          | 4.23          |
| 0.50      | 5.74          | 4.43          |
| 1.00      | 4.86          | 4.86          |

FIGURE 8–30

Tube surfaces are often *roughened*, *corrugated*, or *finned* in order to *enhance* convection heat transfer.

FIGURE 8–31

Schematic for Example 8–4.

Since  $Re$  is greater than 10,000, the flow is turbulent. The relative roughness of the tube is

$$\frac{\epsilon}{D} = \frac{0.000007 \text{ ft}}{2/12 \text{ ft}} = 0.000042$$

The friction factor corresponding to this relative roughness and Reynolds number can simply be determined from the Moody chart. To avoid the reading error, we determine it from the Colebrook equation:

$$\frac{1}{\sqrt{f}} = -2.0 \log \left( \frac{\epsilon/D}{3.7} + \frac{2.51}{Re \sqrt{f}} \right) \rightarrow \frac{1}{\sqrt{f}} = -2.0 \log \left( \frac{0.000042}{3.7} + \frac{2.51}{126,400 \sqrt{f}} \right)$$

Using an equation solver or an iterative scheme, the friction factor is determined to be  $f = 0.0174$ . Then the pressure drop and the required power input become

$$\Delta P = f \frac{L}{D} \frac{\rho V^2}{2} = 0.0174 \frac{200 \text{ ft}}{2/12 \text{ ft}} \frac{(62.36 \text{ lbm/ft}^3)(9.17 \text{ ft/s})^2}{2} \left( \frac{1 \text{ lbf}}{32.174 \text{ lbm} \cdot \text{ft/s}^2} \right) \\ = 1700 \text{ lbf/ft}^2 = 11.8 \text{ psi}$$

$$\dot{W}_{\text{pump}} = \dot{V} \Delta P = (0.2 \text{ ft}^3/\text{s})(1700 \text{ lbf/ft}^2) \left( \frac{1 \text{ W}}{0.73756 \text{ lbf} \cdot \text{ft/s}} \right) = 461 \text{ W}$$

Therefore, power input in the amount of 461 W is needed to overcome the frictional losses in the tube.

**Discussion** The friction factor could also be determined easily from the explicit Haaland relation. It would give  $f = 0.0172$ , which is sufficiently close to 0.0174. Also, the friction factor corresponding to  $\epsilon = 0$  in this case is 0.0170, which indicates that this stainless-steel pipe can be assumed to be smooth with negligible error.

### EXAMPLE 8–5 Heating of Water by Resistance Heaters in a Tube

Water is to be heated from 15°C to 65°C as it flows through a 3-cm-internal-diameter 5-m-long tube (Fig. 8–32). The tube is equipped with an electric resistance heater that provides uniform heating throughout the surface of the tube. The outer surface of the heater is well insulated, so that in steady operation all the heat generated in the heater is transferred to the water in the tube. If the system is to provide hot water at a rate of 10 L/min, determine the power rating of the resistance heater. Also, estimate the inner surface temperature of the tube at the exit.

**SOLUTION** Water is to be heated in a tube equipped with an electric resistance heater on its surface. The power rating of the heater and the inner surface temperature at the exit are to be determined.

**Assumptions** 1 Steady flow conditions exist. 2 The surface heat flux is uniform. 3 The inner surfaces of the tube are smooth.

**Properties** The properties of water at the bulk mean temperature of  $T_b = (T_i + T_e)/2 = (15 + 65)/2 = 40^\circ\text{C}$  are (Table A–9)

**FIGURE 8–32**

Schematic for Example 8–5.

$$\begin{aligned}\rho &= 992.1 \text{ kg/m}^3 & c_p &= 4179 \text{ J/kg}\cdot\text{K} \\ k &= 0.631 \text{ W/m}\cdot\text{K} & \text{Pr} &= 4.32 \\ \nu &= \mu/\rho = 0.658 \times 10^{-6} \text{ m}^2/\text{s}\end{aligned}$$

**Analysis** The cross sectional and heat transfer surface areas are

$$A_c = \frac{1}{4}\pi D^2 = \frac{1}{4}\pi(0.03 \text{ m})^2 = 7.069 \times 10^{-4} \text{ m}^2$$

$$A_s = \pi DL = \pi(0.03 \text{ m})(5 \text{ m}) = 0.471 \text{ m}^2$$

The volume flow rate of water is given as  $\dot{V} = 10 \text{ L/min} = 0.01 \text{ m}^3/\text{min}$ . Then the mass flow rate becomes

$$\dot{m} = \rho \dot{V} = (992.1 \text{ kg/m}^3)(0.01 \text{ m}^3/\text{min}) = 9.921 \text{ kg/min} = 0.1654 \text{ kg/s}$$

To heat the water at this mass flow rate from  $15^\circ\text{C}$  to  $65^\circ\text{C}$ , heat must be supplied to the water at a rate of

$$\begin{aligned}\dot{Q} &= \dot{m} c_p(T_e - T_i) \\ &= (0.1654 \text{ kg/s})(4.179 \text{ kJ/kg}\cdot\text{K})(65 - 15)^\circ\text{C} \\ &= 34.6 \text{ kJ/s} = 34.6 \text{ kW}\end{aligned}$$

All of this energy must come from the resistance heater. Therefore, the power rating of the heater must be **34.6 kW**.

The surface temperature  $T_s$  of the tube at any location can be determined from

$$\dot{q}_s = h(T_s - T_m) \rightarrow T_s = T_m + \frac{\dot{q}_s}{h}$$

where  $h$  is the heat transfer coefficient and  $T_m$  is the mean temperature of the fluid at that location. The surface heat flux is constant in this case, and its value can be determined from

$$\dot{q}_s = \frac{\dot{Q}}{A_s} = \frac{34.6 \text{ kW}}{0.471 \text{ m}^2} = 73.46 \text{ kW/m}^2$$

To determine the heat transfer coefficient, we first need to find the mean velocity of water and the Reynolds number:

$$V_{\text{avg}} = \frac{\dot{V}}{A_c} = \frac{0.010 \text{ m}^3/\text{min}}{7.069 \times 10^{-4} \text{ m}^2} = 14.15 \text{ m/min} = 0.236 \text{ m/s}$$

$$\text{Re} = \frac{V_{\text{avg}}D}{\nu} = \frac{(0.236 \text{ m/s})(0.03 \text{ m})}{0.658 \times 10^{-6} \text{ m}^2/\text{s}} = 10,760$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry length is roughly

$$L_h \approx L_t \approx 10D = 10 \times 0.03 = 0.3 \text{ m}$$

which is much shorter than the total length of the tube. Therefore, we can assume fully developed turbulent flow in the entire tube and determine the Nusselt number from

$$\text{Nu} = \frac{hD}{k} = 0.023 \text{ Re}^{0.8} \text{ Pr}^{0.4} = 0.023(10,760)^{0.8} (4.32)^{0.4} = 69.4$$

Then,

$$h = \frac{k}{D} \text{ Nu} = \frac{0.631 \text{ W/m}\cdot\text{K}}{0.03 \text{ m}} (69.4) = 1460 \text{ W/m}^2\cdot\text{K}$$

and the surface temperature of the pipe at the exit becomes

$$T_s = T_m + \frac{\dot{q}_s}{h} = 65^\circ\text{C} + \frac{73,460 \text{ W/m}^2}{1460 \text{ W/m}^2\cdot\text{K}} = 115^\circ\text{C}$$

**Discussion** Note that the inner surface temperature of the tube will be 50°C higher than the mean water temperature at the tube exit. This temperature difference of 50°C between the water and the surface will remain constant throughout the fully developed flow region.

**FIGURE 8–33**

Schematic for Example 8–6.

### PtD EXAMPLE 8–6 Pipe Insulation for Thermal Burn Prevention

A 10-m-long metal pipe ( $k_{\text{pipe}} = 15 \text{ W/m}\cdot\text{K}$ ) has an inner diameter of 5 cm and an outer diameter of 6 cm is used for transporting hot saturated water vapor at a flow rate of 0.05 kg/s (Fig. 8–33). The water vapor enters and exits the pipe at 350°C and 290°C, respectively. In order to prevent thermal burn on individuals working in the vicinity of the pipe, the pipe is covered with a 2.25-cm-thick layer of insulation ( $k_{\text{ins}} = 0.95 \text{ W/m}\cdot\text{K}$ ) to ensure that the outer surface temperature  $T_{s,o}$  is below 45°C. Determine whether or not the thickness of the insulation is sufficient to alleviate the risk of thermal burn hazards.

**SOLUTION** In this example, the concepts of PtD are applied in conjunction with the concepts of internal forced convection and steady one-dimensional heat conduction. The inner pipe surface temperature  $T_{s,i}$  is determined using the concept of internal forced convection. Having determined the inner surface temperature, the outer surface temperature  $T_{s,o}$  is determined using one-dimensional heat conduction through the pipe wall and insulation.

**Assumptions** Steady operating conditions exist. **2** Radiation effects are negligible. **3** Convection effects on the outer pipe surface are negligible. **4** One-dimensional heat conduction through pipe wall and insulation. **5** The thermal conductivities of pipe wall and insulation are constant. **6** Thermal resistance at the interface is negligible. **7** The surface temperatures are uniform. **8** The inner surfaces of the tube are smooth.

**Properties** The properties of saturated water vapor at  $T_b = (T_i + T_e)/2 = 320^\circ\text{C}$  are  $c_p = 7900 \text{ J/kg}\cdot\text{K}$ ,  $k = 0.0836 \text{ W/m}\cdot\text{K}$ ,  $\mu = 2.084 \times 10^{-5} \text{ kg/m}\cdot\text{s}$ , and  $\text{Pr} = 1.97$  (Table A–9). The thermal conductivities of the pipe and the insulation are given to be  $k_{\text{pipe}} = 15 \text{ W/m}\cdot\text{K}$  and  $k_{\text{ins}} = 0.95 \text{ W/m}\cdot\text{K}$ , respectively.

**Analysis** The Reynolds number of the saturated water vapor flow in the pipe is

$$\text{Re} = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4(0.05 \text{ kg/s})}{\pi(0.05 \text{ m})(2.084 \times 10^{-5} \text{ kg/m}\cdot\text{s})} = 61,096 > 10,000$$

Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10(0.05 \text{ m}) = 0.5 \text{ m} \text{ (assume fully developed turbulent flow)}$$

The Nusselt number can be determined from the Gnielinski correlation:

$$\text{Nu} = \frac{(f/8)(\text{Re} - 1000)\text{Pr}}{1 + 12.7(f/8)^{0.5}(\text{Pr}^{2/3} - 1)} = \frac{(0.02003/8)(61,096 - 1000)(1.97)}{1 + 12.7(0.02003/8)^{0.5}(1.97^{2/3} - 1)} = 217.45$$

$$\text{where } f = (0.790 \ln \text{Re} - 1.64)^{-2} = 0.02003$$

Thus, the convection heat transfer coefficient for the saturated water vapor flow inside the pipe is

$$h = \frac{k}{D_i} \text{Nu} = \frac{0.0836 \text{ W/m}\cdot\text{K}}{0.05 \text{ m}} (217.45) = 363.58 \text{ W/m}^2\cdot\text{K}$$

The inner pipe surface temperature is

$$T_e = T_{s,i} - (T_{s,i} - T_i) \exp\left(-\frac{hA_s}{\dot{m}c_p}\right) \longrightarrow T_{s,i} = 271.52^\circ\text{C}$$

$$\text{where } A_s = \pi(0.05 \text{ m})(10 \text{ m}) = 1.571 \text{ m}^2$$

From Chapter 3, the thermal resistances for the pipe wall and the insulation are

$$R_{\text{pipe}} = \frac{\ln(D_{\text{interface}}/D_i)}{2\pi k_{\text{pipe}} L} = \frac{\ln(0.06/0.05)}{2\pi(15 \text{ W/m}\cdot\text{K})(10 \text{ m})} = 1.9345 \times 10^{-4} \text{ K/W}$$

$$R_{\text{ins}} = \frac{\ln(D_o/D_{\text{interface}})}{2\pi k_{\text{ins}} L} = \frac{\ln(0.105/0.06)}{2\pi(0.95 \text{ W/m}\cdot\text{K})(10 \text{ m})} = 9.3753 \times 10^{-3} \text{ K/W}$$

$$\text{where } D_o = 0.06 \text{ m} + 2(0.0225 \text{ m}) = 0.105 \text{ m}$$

The total thermal resistance and the rate of heat transfer are

$$R_{\text{total}} = R_{\text{pipe}} + R_{\text{ins}} = 9.5688 \times 10^{-3} \text{ K/W} \text{ and } \dot{Q} = \frac{T_{s,i} - T_{s,o}}{R_{\text{total}}} = \dot{m}c_p(T_i - T_e)$$

Thus, the outer surface temperature is

$$\begin{aligned} T_{s,o} &= T_{s,i} - R_{\text{total}}\dot{m}c_p(T_i - T_e) \\ &= 271.52^\circ\text{C} - (9.5688 \times 10^{-3} \text{ K/W})(0.05 \text{ kg/s})(7900 \text{ J/kg}\cdot\text{K})(350 - 290)^\circ\text{C} \\ &= 44.7^\circ\text{C} \end{aligned}$$

**Discussion** The insulation thickness of 2.25 cm is just barely sufficient to keep the outer surface temperature below 45°C. To ensure the outer surface to be a few degrees below 45°C, the insulation thickness should be increased slightly to 2.3 cm, which would make  $T_{s,o} = 41^\circ\text{C}$ .

**FIGURE 8–34**  
Schematic for Example 8–7.

### EXAMPLE 8–7 Heat Loss from the Ducts of a Heating System

Hot air at atmospheric pressure and  $80^\circ\text{C}$  enters an 8-m-long uninsulated square duct of cross section  $0.2 \text{ m} \times 0.2 \text{ m}$  that passes through the attic of a house at a rate of  $0.15 \text{ m}^3/\text{s}$  (Fig. 8–34). The duct is observed to be nearly isothermal at  $60^\circ\text{C}$ . Determine the exit temperature of the air and the rate of heat loss from the duct to the attic space.

**SOLUTION** Heat loss from uninsulated square ducts of a heating system in the attic is considered. The exit temperature and the rate of heat loss are to be determined.

**Assumptions** 1 Steady operating conditions exist. 2 The inner surfaces of the duct are smooth. 3 Air is an ideal gas.

**Properties** We do not know the exit temperature of the air in the duct, and thus we cannot determine the bulk mean temperature of air, which is the temperature at which the properties are to be determined. The temperature of air at the inlet is  $80^\circ\text{C}$ , and we expect this temperature to drop somewhat as a result of heat loss through the duct whose surface is at  $60^\circ\text{C}$ . At  $80^\circ\text{C}$  and 1 atm we read (Table A–15)

$$\begin{aligned}\rho &= 0.9994 \text{ kg/m}^3 & c_p &= 1008 \text{ J/kg}\cdot\text{K} \\ k &= 0.02953 \text{ W/m}\cdot\text{K} & \text{Pr} &= 0.7154 \\ \nu &= 2.097 \times 10^{-5} \text{ m}^2/\text{s}\end{aligned}$$

**Analysis** The characteristic length (which is the hydraulic diameter), the mean velocity, and the Reynolds number in this case are

$$\begin{aligned}D_h &= \frac{4A_c}{p} = \frac{4a^2}{4a} = a = 0.2 \text{ m} \\ V_{\text{avg}} &= \frac{\dot{V}}{A_c} = \frac{0.15 \text{ m}^3/\text{s}}{(0.2 \text{ m})^2} = 3.75 \text{ m/s} \\ \text{Re} &= \frac{V_{\text{avg}} D_h}{\nu} = \frac{(3.75 \text{ m/s})(0.2 \text{ m})}{2.097 \times 10^{-5} \text{ m}^2/\text{s}} = 35,765\end{aligned}$$

which is greater than 10,000. Therefore, the flow is turbulent and the entry lengths in this case are roughly

$$L_h \approx L_t \approx 10D = 10 \times 0.2 \text{ m} = 2 \text{ m}$$

which is much shorter than the total length of the duct. Therefore, we can assume fully developed turbulent flow in the entire duct and determine the Nusselt number from

$$\text{Nu} = \frac{hD_h}{k} = 0.023 \text{ Re}^{0.8} \text{ Pr}^{0.3} = 0.023(35,765)^{0.8} (0.7154)^{0.3} = 91.4$$

Then,

$$h = \frac{k}{D_h} \text{ Nu} = \frac{0.02953 \text{ W/m}\cdot\text{K}}{0.2 \text{ m}} (91.4) = 13.5 \text{ W/m}^2\cdot\text{K}$$

$$A_s = 4aL = 4 \times (0.2 \text{ m})(8 \text{ m}) = 6.4 \text{ m}^2$$

$$\dot{m} = \rho \dot{V} = (0.9994 \text{ kg/m}^3)(0.15 \text{ m}^3/\text{s}) = 0.150 \text{ kg/s}$$

Next, we determine the exit temperature of air from

$$\begin{aligned} T_e &= T_s - (T_s - T_i) \exp(-hA_s/\dot{m}c_p) \\ &= 60^\circ\text{C} - [(60 - 80)^\circ\text{C}] \exp\left[-\frac{(13.5 \text{ W/m}^2\text{-K})(6.4 \text{ m}^2)}{(0.150 \text{ kg/s})(1008 \text{ J/kg-K})}\right] \\ &= \mathbf{71.3^\circ\text{C}} \end{aligned}$$

Then the log mean temperature difference and the rate of heat loss from the air become

$$\Delta T_{lm} = \frac{T_i - T_e}{\ln \frac{T_s - T_e}{T_s - T_i}} = \frac{80 - 71.3}{\ln \frac{60 - 71.3}{60 - 80}} = -15.2^\circ\text{C}$$

$$\dot{Q} = hA_s \Delta T_{lm} = (13.5 \text{ W/m}^2\text{-K})(6.4 \text{ m}^2)(-15.2^\circ\text{C}) = \mathbf{-1313 \text{ W}}$$

Therefore, air will lose heat at a rate of 1313 W as it flows through the duct in the attic.

**Discussion** The average fluid temperature is  $(80 + 71.3)/2 = 75.7^\circ\text{C}$ , which is sufficiently close to  $80^\circ\text{C}$ , at which we evaluated the properties of air. Therefore, it is not necessary to reevaluate the properties at this temperature and to repeat the calculations.

## TOPIC OF SPECIAL INTEREST\*

### *Transitional Flow in Tubes*

An important design problem in industrial heat exchangers arises when flow inside the tubes falls into the transition region. In practical engineering design, the usual recommendation is to avoid design and operation in this region; however, this is not always feasible under design constraints. The usually cited transitional Reynolds number range of about 2300 (onset of turbulence) to 10,000 (fully turbulent condition) applies, strictly speaking, to a very steady and uniform entry flow with a rounded entrance. If the flow has a disturbed entrance typical of heat exchangers, in which there is a sudden contraction and possibly even a re-entrant entrance, the transitional Reynolds number range will be much different.

Ghajar and coworkers in a series of papers (listed in the references) have experimentally investigated the inlet configuration effects on the fully developed transitional pressure drop under isothermal and heating conditions, as well as developing and fully developed transitional forced and mixed convection heat transfer in circular tubes. Based on their experimental data, they have developed practical and easy to use correlations for the friction coefficient and the Nusselt number in the transition region between laminar and turbulent flows. This section provides a brief summary of their work in the transition region.

---

\*This section can be skipped without a loss of continuity.

**FIGURE 8–35**

Schematic of the three different inlet configurations.

## Pressure Drop in the Transition Region

Pressure drops are measured in circular tubes for fully developed flows in the transition regime for three types of inlet configurations shown in Fig. 8–35: re-entrant (tube extends beyond tubesheet face into head of distributor), square-edged (tube end is flush with tubesheet face), and bell-mouth (a tapered entrance of tube from tubesheet face) under isothermal and heating conditions, respectively. The widely used expressions for the *friction factor*  $f$  (also called the *Darcy friction factor*) or the *friction coefficient*  $C_f$  (also called the *Fanning friction factor*) in laminar and turbulent flows with heating are

$$f_{\text{lam}} = 4C_{f,\text{lam}} = 4 \left( \frac{16}{\text{Re}} \right) \left( \frac{\mu_b}{\mu_s} \right)^m \quad (8-81)$$

$$f_{\text{turb}} = 4C_{f,\text{turb}} = 4 \left( \frac{0.0791}{\text{Re}^{0.25}} \right) \left( \frac{\mu_b}{\mu_s} \right)^m \quad (8-82)$$

where the factors at the end account for the wall temperature effect on viscosity. The exponent  $m$  for laminar flows depends on a number of factors, while for turbulent flows the most typically quoted value for heating is  $-0.25$ . The transition friction factor is given as [Tam and Ghajar, 1997]

$$f_{\text{trans}} = 4C_{f,\text{trans}} = 4 \left[ 1 + \left( \frac{\text{Re}}{A} \right)^B \right]^C \left( \frac{\mu_b}{\mu_s} \right)^m \quad (8-83)$$

where

$$m = m_1 - m_2 \text{Gr}^{m_3} \text{Pr}^{m_4} \quad (8-84)$$

and the Grashof number (Gr) which is a dimensionless number representing the ratio of the buoyancy force to the viscous force is defined as  $\text{Gr} = g\beta D^3 (T_s - T_b)/\nu^2$  (see Chapter 9 for more details). All properties appearing in the dimensionless numbers  $C_f$ ,  $f$ ,  $\text{Re}$ ,  $\text{Pr}$ , and  $\text{Gr}$  are evaluated at the bulk fluid temperature  $T_b$ . The values of the empirical constants in Eqs. 8–83 and 8–84 are listed in Table 8–5. The range of application of Eq. 8–83 for the transition friction factor is as follows:

*Re-entrant:*  $2700 \leq \text{Re} \leq 5500$ ,  $16 \leq \text{Pr} \leq 35$ ,  $7410 \leq \text{Gr} \leq 158,300$ ,  $1.13 \leq \mu_b/\mu_s \leq 2.13$

*Square-edged:*  $3500 \leq \text{Re} \leq 6900$ ,  $12 \leq \text{Pr} \leq 29$ ,  $6800 \leq \text{Gr} \leq 104,500$ ,  $1.11 \leq \mu_b/\mu_s \leq 1.89$

*Bell-mouth:*  $5900 \leq \text{Re} \leq 9600$ ,  $8 \leq \text{Pr} \leq 15$ ,  $11,900 \leq \text{Gr} \leq 353,000$ ,  $1.05 \leq \mu_b/\mu_s \leq 1.47$

**TABLE 8–5**

Constants for transition friction coefficient correlation

| Inlet Geometry | $A$  | $B$     | $C$   | $m_1$ | $m_2$ | $m_3$  | $m_4$ |
|----------------|------|---------|-------|-------|-------|--------|-------|
| Re-entrant     | 5840 | -0.0145 | -6.23 | -1.10 | 0.460 | -0.133 | 4.10  |
| Square-edged   | 4230 | -0.1600 | -6.57 | -1.13 | 0.396 | -0.160 | 5.10  |
| Bell-mouth     | 5340 | -0.0990 | -6.32 | -2.58 | 0.420 | -0.410 | 2.46  |

**FIGURE 8–36**

Fully developed friction coefficients for three different inlet configurations and heat fluxes (filled symbols designate the start and end of the transition region for each inlet).

From Tam and Ghajar, 1997.

These correlations captured about 82% of measured data within an error band of  $\pm 10\%$ , and 98% of measured data with  $\pm 20\%$ . For laminar flows with heating, Tam and Ghajar give the following constants for determining the exponent  $m$  in Eq. 8–81:  $m_1 = 1.65$ ,  $m_2 = 0.013$ ,  $m_3 = 0.170$ , and  $m_4 = 0.840$ , which is applicable over the following range of parameters:

$$1100 \leq Re \leq 7400, 6 \leq Pr \leq 36, 17,100 \leq Gr \leq 95,600, \\ \text{and } 1.25 \leq \mu_b/\mu_s \leq 2.40.$$

The fully developed friction coefficient results for the three different inlet configurations shown in Fig. 8–36 clearly establish the influence of heating rate on the beginning and end of the transition regions, for each inlet configuration. In the laminar and transition regions, heating seems to have a significant influence on the value of the friction coefficient. However, in the turbulent region, heating did not affect the magnitude of the friction coefficient. The significant influence of heating on the values of friction coefficient in the laminar and transition regions is directly due to the effect of secondary flow.

The isothermal friction coefficients for the three inlet types showed that the range of the Reynolds number values at which transition flow exists is strongly inlet-geometry dependent. Furthermore, heating caused an increase in the laminar and turbulent friction coefficients and an increase in the lower and upper limits of the isothermal transition regime boundaries. The friction coefficient transition Reynolds number ranges for the isothermal and nonisothermal (three different heating rates) and the three different inlets used in their study are summarized in Table 8–6.

**TABLE 8–6**

Transition Reynolds numbers for friction coefficient

| Heat Flux                             | Re-entrant         | Square-Edged       | Bell-Mouth         |
|---------------------------------------|--------------------|--------------------|--------------------|
| 0 $\text{kW}/\text{m}^2$ (isothermal) | $2870 < Re < 3500$ | $3100 < Re < 3700$ | $5100 < Re < 6100$ |
| 3 $\text{kW}/\text{m}^2$              | $3060 < Re < 3890$ | $3500 < Re < 4180$ | $5930 < Re < 8730$ |
| 8 $\text{kW}/\text{m}^2$              | $3350 < Re < 4960$ | $3860 < Re < 5200$ | $6480 < Re < 9110$ |
| 16 $\text{kW}/\text{m}^2$             | $4090 < Re < 5940$ | $4450 < Re < 6430$ | $7320 < Re < 9560$ |

**FIGURE 8-37**

Influence of different inlet configurations on the isothermal fully developed friction coefficients (filled symbols designate the start and end of the transition region for each inlet).

From Tam and Ghajar, 1997.

Figure 8-37 shows the influence of inlet configuration on the beginning and end of the isothermal fully developed friction coefficients in the transition region.

Note that the isothermal fully developed friction coefficients in the laminar, turbulent, and transition regions can be obtained easily from Eqs. 8-81, 8-82, and 8-83, respectively, by setting the viscosity ratio correction to unity (i.e., set  $m = 0$ ).

The results presented so far were based on the experimental work of Tam and Ghajar (1997) for fully developed isothermal and non-isothermal friction factors. Ghajar and coworkers conducted similar experiments in the entrance (developing) region for square-edged and re-entrant inlets for laminar and transitional flows [Tam et al. (2013)]. The developing friction factor is referred to as the *apparent friction factor*. The apparent friction factor accounts for the combined effects of flow acceleration (variation in momentum flux) and surface shear forces.

For laminar developing friction factor in tubes with square-edged and re-entrant inlets, they recommended the following correlation.

$$f_{\text{app,lam}} = \left[ \frac{1}{\text{Re}} \left( 64 + \frac{0.01256}{4.836 \times 10^{-5} + 0.0609 \left( \frac{x/D}{\text{Re}} \right)^{1.28}} \right) \right] \left( \frac{\mu_b}{\mu_s} \right)^m \quad (8-85)$$

where  $m = -5.06 + 0.84 \times \text{Pr}^{0.23} \text{Gr}^{0.09}$  for non-isothermal flow and  $m = 0$  for isothermal flow.

The range of application of Eq. 8-85 is:  $897 \leq \text{Re} \leq 2189$ ,  $7141 \leq \text{Gr} \leq 18,224$ ,  $1.27 \leq \mu_b/\mu_s \leq 1.56$ ,  $39 \leq \text{Pr} \leq 47$ , and  $3 \leq x/D \leq 200$ .

For transitional developing friction factor in tubes they recommended the following correlation.

$$f_{\text{app,trans}} = \left\{ \left( \frac{64}{\text{Re}} \right) \left[ (1 + (0.0049 \text{Re}^{0.75})^a)^{1/a} + b \right] \left[ 1 + \left( \frac{c}{x/D} \right) \right] \right\} \left( \frac{\mu_b}{\mu_s} \right)^m \quad (8-86)$$

where the exponent  $m$  is obtained separately for each inlet for non-isothermal flow from Table 8-7 and is set to  $m = 0$  for isothermal flow. The constants in Eq. 8-86 and its range of application for each inlet are also given in Table 8-7.

**TABLE 8-7**

Constants and ranges of independent variables for transition friction factor correlation

| Inlet Geometry | Constants and ranges of independent variables  |
|----------------|--|
| Re-entrant     | $a = 0.52, b = -3.47, c = 4.8, m = -1.8 + 0.46 \text{Gr}^{-0.13} \text{Pr}^{0.41}$<br>$1883 < \text{Re} < 3262, 19.1 < \text{Pr} < 46.5, 4560 < \text{Gr} < 24,339,$<br>$1.12 < \mu_b/\mu_s < 1.54, 3 < x/D < 200$ |
| Square-edged   | $a = 0.50, b = -4.0, c = 3.0, m = -1.13 + 0.48 \text{Gr}^{-0.15} \text{Pr}^{0.55}$<br>$2084 < \text{Re} < 3980, 19.6 < \text{Pr} < 47.3, 6169 < \text{Gr} < 35,892,$<br>$1.10 < \mu_b/\mu_s < 1.54, 3 < x/D < 200$ |

**EXAMPLE 8–8 Nonisothermal Fully Developed Friction Coefficient in the Transition Region**

A tube with a bell-mouth inlet configuration is subjected to  $8 \text{ kW/m}^2$  uniform wall heat flux. The tube has an inside diameter of  $0.0158 \text{ m}$  and a flow rate of  $1.32 \times 10^{-4} \text{ m}^3/\text{s}$ . The liquid flowing inside the tube is ethylene glycol-distilled water mixture with a mass fraction of 0.34. The properties of the ethylene glycol-distilled water mixture at the location of interest are  $\text{Pr} = 11.6$ ,  $\nu = 1.39 \times 10^{-6} \text{ m}^2/\text{s}$ , and  $\mu_b/\mu_s = 1.14$ . Determine the fully developed friction coefficient at a location along the tube where the Grashof number is  $\text{Gr} = 60,800$ . What would the answer be if a square-edged inlet is used instead?

**SOLUTION** A liquid mixture flowing in a tube is subjected to uniform wall heat flux. The friction coefficients are to be determined for the bell-mouth and square-edged inlet cases.

**Assumptions** Steady operating conditions exist.

**Properties** The properties of the ethylene glycol-distilled water mixture are given to be  $\text{Pr} = 11.6$ ,  $\nu = 1.39 \times 10^{-6} \text{ m}^2/\text{s}$ , and  $\mu_b/\mu_s = 1.14$ .

**Analysis** For the calculation of the nonisothermal fully developed friction coefficient, it is necessary to determine the flow regime before making any decision regarding which friction coefficient relation to use. The Reynolds number at the specified location is

$$\text{Re} = \frac{(\dot{V}/A_c)D}{\nu} = \frac{[(1.32 \times 10^{-4} \text{ m}^3/\text{s})/(1.961 \times 10^{-4} \text{ m}^2)](0.0158 \text{ m})}{1.39 \times 10^{-6} \text{ m}^2/\text{s}} = 7651$$

since

$$A_c = \pi D^2/4 = \pi(0.0158 \text{ m})^2/4 = 1.961 \times 10^{-4} \text{ m}^2$$

From Table 8–6, we see that for a bell-mouth inlet and a heat flux of  $8 \text{ kW/m}^2$  the flow is in the transition region. Therefore, Eq. 8–83 applies. Reading the constants  $A$ ,  $B$ , and  $C$  and  $m_1$ ,  $m_2$ ,  $m_3$ , and  $m_4$  from Table 8–5, the friction coefficient is determined to be

$$\begin{aligned} C_{f,\text{trans}} &= \left[ 1 + \left( \frac{\text{Re}}{A} \right)^B \right]^C \left( \frac{\mu_b}{\mu_s} \right)^m \\ &= \left[ 1 + \left( \frac{7651}{5340} \right)^{-0.099} \right]^{-6.32} (1.14)^{-2.58 - 0.42 \times 60,800^{-0.41} \times 11.6^{2.46}} = \mathbf{0.010} \end{aligned}$$

**Square-Edged Inlet Case** For this inlet shape, the Reynolds number of the flow is the same as that of the bell-mouth inlet ( $\text{Re} = 7651$ ). However, it is necessary to check the type of flow regime for this particular inlet with  $8 \text{ kW/m}^2$  of heating. From Table 8–6, the transition Reynolds number range for this case is  $3860 < \text{Re} < 5200$ , which means that the flow in this case is turbulent and Eq. 8–82 is the appropriate equation to use. It gives

$$C_{f,\text{turb}} = \left( \frac{0.0791}{\text{Re}^{0.25}} \right) \left( \frac{\mu_b}{\mu_s} \right)^m = \left( \frac{0.0791}{7651^{0.25}} \right) (1.14)^{-0.25} = \mathbf{0.0082}$$

**Discussion** Note that the friction factors  $f$  can be determined by multiplying the friction coefficient values by 4.

## Heat Transfer in the Transition Region

Ghajar and coworkers also experimentally investigated the inlet configuration effects on heat transfer in the transition region between laminar and turbulent flows in tubes for the same three inlet configurations shown in Fig. 8–35. They proposed some prediction methods for this regime to bridge between laminar methods and turbulent methods, applicable to forced and mixed convection in the entrance and fully developed regions for the three types of inlet configurations, which are presented next. For a detailed discussion on this topic refer to Tam and Ghajar (2006). The local heat transfer coefficient in transition flow is obtained from the transition Nusselt number,  $\text{Nu}_{\text{trans}}$ , which is calculated as follows at a distance  $x$  from the entrance:

$$\text{Nu}_{\text{trans}} = \text{Nu}_{\text{lam}} + \{\exp[(a - \text{Re})/b] + \text{Nu}_{\text{turb}}^c\}^c \quad (8-87)$$

where  $\text{Nu}_{\text{lam}}$  is the laminar flow Nusselt number for entrance region laminar flows with natural convection effects,

$$\text{Nu}_{\text{lam}} = 1.24 \left[ \left( \frac{\text{RePr}D}{x} \right) + 0.025(\text{GrPr})^{0.75} \right]^{1/3} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad (8-88)$$

and  $\text{Nu}_{\text{turb}}$  is the turbulent flow Nusselt number with developing flow effects,

$$\text{Nu}_{\text{turb}} = 0.023\text{Re}^{0.8}\text{Pr}^{0.385} \left( \frac{x}{D} \right)^{-0.0054} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad (8-89)$$

The physical properties appearing in the dimensionless numbers Nu, Re, Pr, and Gr all are evaluated at the bulk fluid temperature  $T_b$ . The values of the empirical constants  $a$ ,  $b$ , and  $c$  in Eq. 8–87 depend on the inlet configuration and are given in Table 8–8. The viscosity ratio accounts for the temperature effect on the process. The range of application of the heat transfer method based on their database of 1290 points (441 points for re-entrant inlet, 416 for square-edged inlet, and 433 points for bell-mouth inlet) is as follows:

*Re-entrant:*  $3 \leq x/D \leq 192$ ,  $1700 \leq \text{Re} \leq 9100$ ,  $5 \leq \text{Pr} \leq 51$ ,  $4000 \leq \text{Gr} < 210,000$ ,  $1.2 < \mu_b/\mu_s < 2.2$

*Square-edged:*  $3 \leq x/D \leq 192$ ,  $1600 \leq \text{Re} \leq 10,700$ ,  $5 \leq \text{Pr} \leq 55$ ,  $4000 \leq \text{Gr} \leq 250,000$ ,  $1.2 \leq \mu_b/\mu_s \leq 2.6$

*Bell-mouth:*  $3 \leq x/D \leq 192$ ,  $3300 \leq \text{Re} \leq 11,100$ ,  $13 \leq \text{Pr} \leq 77$ ,  $6000 \leq \text{Gr} \leq 110,000$ ,  $1.2 \leq \mu_b/\mu_s \leq 3.1$

These correlations capture about 70 percent of measured data within an error band of  $\pm 10\%$ , and 97% of measured data with  $\pm 20\%$ , which is remarkable for transition flows. The individual expressions above for  $\text{Nu}_{\text{lam}}$  and  $\text{Nu}_{\text{turb}}$  can be used alone for developing flows in those respective regimes. The lower and upper limits of the heat transfer transition Reynolds number ranges for the three different inlets are summarized in Table 8–9. The results shown in this table indicate that the re-entrant inlet configuration causes the earliest transition from laminar flow into the transition regime (at about 2000) while the bell-mouth entrance retards this regime change (at about 3500). The square-edged entrance falls in between (at about 2400), which is close to the often quoted value of 2300 in most textbooks.

TABLE 8–8

Constants for transition heat transfer correlation

| Inlet Geometry | $a$  | $b$ | $c$    |
|----------------|------|-----|--------|
| Re-entrant     | 1766 | 276 | -0.955 |
| Square-edged   | 2617 | 207 | -0.950 |
| Bell-mouth     | 6628 | 237 | -0.980 |

**TABLE 8–9**

The lower and upper limits of the heat transfer transition Reynolds numbers

| Inlet Geometry | Lower Limit                             | Upper Limit                               |
|----------------|---|---|
| Re-entrant     | $Re_{lower} = 2157 - 0.65[192 - (x/D)]$ | $Re_{upper} = 8475 - 9.28[192 - (x/D)]$   |
| Square-edged   | $Re_{lower} = 2524 - 0.82[192 - (x/D)]$ | $Re_{upper} = 8791 - 7.69[192 - (x/D)]$   |
| Bell-mouth     | $Re_{lower} = 3787 - 1.80[192 - (x/D)]$ | $Re_{upper} = 10,481 - 5.47[192 - (x/D)]$ |

Figure 8–38 clearly shows the influence of inlet configuration on the beginning and end of the heat transfer transition region. This figure plots the local average peripheral heat transfer coefficients in terms of the Colburn  $j_H$  factor ( $j_H = St Pr^{0.67}$ ) versus local Reynolds number for all flow regimes at the length-to-diameter ratio of 192, and  $St$  is the Stanton number, which is also a dimensionless heat transfer coefficient (see Chapter 6 for more details), defined as  $St = Nu/(Re Pr)$ . The filled symbols in Fig. 8–38 represent the start and end of the heat transfer transition region for each inlet configuration. Note the large influence of natural convection superimposed on the forced convective laminar-flow heat transfer process ( $Nu = 4.364$  for a fully developed laminar flow with a uniform heat-flux boundary condition without buoyancy effects), yielding a mixed convection value of about  $Nu = 14.5$ . Equation 8–88 includes this buoyancy effect through the Grashof number.
